

Earth System Modeling Framework

ESMF User Guide

Version 2.1

ESMF Joint Specification Team: V. Balaji, Byron Boville, Nancy Collins, Tony Craig, Carlos Cruz, Arlindo da Silva, Cecelia DeLuca, Brian Eaton, Bob Hallberg, Chris Hill, Mark Iredell, Rob Jacob, Phil Jones, Brian Kauffman, Jay Larson, John Michalakes, David Neckels, Chuck Panaccione, Jim Rosinski, Earl Schwab, Shepard Smithline, Max Suarez, Spencer Swift, Gerhard Theurich, Silverio Vasquez, Jon Wolfe, Weiyu Yang, Mike Young, Leonid Zaslavsky

11th March 2005

Acknowledgements

The ESMF software is based on the contributions of a broad community. Below are the software packages that are included in ESMF or strongly influenced our design. We'd like to express our gratitude to the developers of these codes for access to their software as well as their ideas and advice.

- The Spherical Coordinate Remapping and Interpolation Package (SCRIP) from Los Alamos, on which we based our regridding functionality with the help of SCRIP author Phil Jones
- The Inpack configuration attributes package from NASA Goddard, which was adapted for use in ESMF by members of NASA Global Modeling and Assimilation group
- The Flexible Modeling System (FMS) package from GFDL and the Goddard Earth Modeling System (GEMS) from NASA Goddard, both of which provided inspiration for overall ESMF structure
- The Weather Research and Forecast (WRF) modeling system, on which we based our underlying I/O implementation
- The Common Component Architecture (CCA) effort within the DoE, from which we drew many ideas about how to design components
- The Portable, Extensible Toolkit for Scientific Computation (PETSc) package from Argonne National Laboratories, on which we based our initial makefile system

1 Release Notes

ESMF v2.1 is a first usable release of the Earth System Modeling Framework. While the ESMF still has much growing to do over the coming years, we expect modelers to find in this release tools that benefit real codes. You may choose to start with the highest level of functionality in the framework, the software for representing models as components and coupling them to other models; or the lowest level, the toolkits for data communication, I/O, logging, or calendar management. Wherever you begin, we hope that you find the ESMF useful, and look forward to hearing your comments on any aspect of the software. Section 4 of this document includes instructions on submitting comments on ESMF to our development team.

2 What is the Earth System Modeling Framework?

The Earth System Modeling Framework (ESMF) is a structured collection of software building blocks that can be used or customized to develop Earth system model components, and assemble them into applications. The simplest view of the ESMF is that it consists of an *infrastructure* of utilities and data structures for creating model components, and a *superstructure* for coupling them. User code sits between these two layers, making calls to the infrastructure libraries beneath it and being scheduled and synchronized by the superstructure above it. The configuration resembles a sandwich, as shown in Figure 1.

The ESMF architecture is a scalable, flexible paradigm for building highly complex climate, weather, and related applications from components such as atmospheric models, land models, and data assimilation systems. The ESMF is not a single master application into which all components must fit; rather it is a way of developing components so that they can be used in many different user-written applications. Model components that adopt ESMF are usable in different contexts without code modification, and may be incorporated into other ESMF-based modeling systems within the Earth science community. In addition to high-level organization, ESMF provides a set of robust, portable, performance optimized libraries for regridding, data transfers, I/O, time management, and other common modeling functions. ESMF users may choose to extensively rewrite their codes to take advantage of the ESMF infrastructure, or they may decide to simply wrap user-written components in ESMF interfaces in order to adopt the ESMF architecture and utilize framework coupling services.

3 The ESMF User's Guide

This *ESMF User's Guide* will eventually serve as an introduction for the new ESMF user and as a reference for the experienced user. This edition of the *User's Guide* is designed to guide you through the introduction process to the software. We strongly encourage you to download the ESMF software and try running a demonstration program, `ESMF_COUPLED_FLOW`, that illustrates both ESMF utilities and coupling services.

The next two sections, 4 and 5, concern user support and how to submit comments on the ESMF system to our development team. Section 6 contains a *Quick Start* guide that explains how to install the ESMF software and run the demonstration program. Section 7 is an architectural overview that describes the framework's basic goals and features. The next few Sections, beginning with 8, describe in detail the `ESMF_COUPLED_FLOW` demo application. More detail on ESMF structure and operation, such as a description of the directory structure and how to run the ESMF self-tests, is provided in Section 11. Section 12 details the steps required to adapt a component for use with ESMF. Finally, to help you become familiar with ESMF terminology, the last section in the *User's Guide* is a glossary.

4 How to Contact User Support and Find Additional Information

The ESMF team can provide assistance in using the framework in your applications. For user support, please contact `esmf_support@ucar.edu`.

Figure 1: Schematic of the ESMF “sandwich” architecture. In this design the framework consists of two parts, an upper level **superstructure** layer and a lower-level **infrastructure** layer. User code is sandwiched between these two layers.

More information on the ESMF project as a whole is available on the ESMF website, <http://www.esmf.ucar.edu>. The website includes a description of ESMF testbed applications, related projects, the ESMF management structure, and much more. Those curious about specific interfaces should refer to the *ESMF Reference Manual for Fortran*, which contains a detailed listing and description of the ESMF API. Other documents available on the ESMF site include an exhaustive *ESMF Requirements Document* and an *ESMF Developer's Guide* that details our project procedures and conventions.

5 How to Submit New Requirements

The **Development** link on the ESMF website includes on-line forms for the submission of new requirements, if it seems that the current API does not satisfy the needs of your application. We welcome input on any aspect of the ESMF project; general questions and comments should be sent to esmf@ucar.edu.

6 Quick Start

This section describes how to get the ESMF software, install it, and run a demonstration application. More detailed information about setting up the ESMF, such as how to modify library paths in the makefiles and how to run diagnostic self-tests, can be found in Section 11.

6.1 ESMF Download Options

Major releases of the ESMF software can be downloaded by following the instructions on the the **Downloads & Documentation** link on the ESMF website, <http://www.esmf.ucar.edu>.

The ESMF is distributed as a full source code tree. You will need to compile the code into the `libesmf.a` library. On some platforms a shared library, `libesmf.so`, is also created. Follow the instructions in the following sections of the *Quick Start* guide, beginning with Section 6.2, Installation, to build the library and link it with your application.

6.2 Installation

6.2.1 System Requirements

The following compilers and utilities are required for compiling and linking the ESMF software:

- a Fortran90 compiler and libraries;
- a C++ compiler;
- if the C++ compiler is not gcc, a gcc compiler - we need this for a standard cpp preprocessor implementation;
- a MPI implementation compatible with these compilers (but see below);
- the GNU make utility;
- the tar utility, for unpacking data files;
- the GNU zip utility, for unpacking data files;
- the Perl programming language, for running test scripts.

An alternative to the MPI library is provided with the ESMF, a single-process MPI-bypass library. It allows applications which use MPI to be linked but only run single process.

In order to build html and pdf version of the ESMF documentation, \LaTeX , the latex2html conversion utility, and the Unix/Linux dvipdf utility must be installed.

6.2.2 ESMF Environment Variables

Currently the `ESMF_DIR` environment variable must be set on all platforms. `ESMF_DIR` should be set to the path of the top level ESMF directory.

There are several other environment variables that the build system uses. In most cases they do not have to be set by the user. If they are not set, then the build system will assign default values to them. For the current supported platforms, the default values are fine. The other environment variables are:

ESMF_ARCH Variable that has the value of `uname -s`. For example, this will be AIX for IBM RS6000's.

There should be no reason for the user to set `ESMF_ARCH` since the proper value should be determined automatically.

ESMF_BOPT Build option value of `g` (for debug mode) or `O` (for optimize mode). Default value will be `O`.

ESMF_COMM Defines which MPI communications library to use. Many times a machine will come with its own MPI library and in those cases the default setting will be the native mpi. Otherwise the default setting will be mpiuni so that the mpi stub library will be used. This is the case for Linux and Darwin systems. Other possible settings are mpich and lam.

ESMF_COMPILER Variable specifying which compiler to use. Value can be default, absoft, intel, lahey, nag, pgi, or xlf. If the value is default or ESMF_COMPILER is left unset, then the default compiler will be used. On systems which usually come with a single vendor-supplied compiler, the default is to use this compiler. On systems like Linux clusters where there is no single vendor compiler installed on all systems, you will generally want to set this. The default for Linux systems is lahey and on Darwin (Mac OS X) systems it is absoft.

ESMF_C_COMPILER Variable specifying which C/C++ compiler to use. In most cases this should not be set; the default is to use the vendor-supplied compilers on those systems which normally come with a single development environment; on other systems like Linux clusters, the default is to use the ESMF_COMPILER setting. However, some Fortran compilers support linking with C and C++ code compiled with the GNU compilers; in these cases, you can set this variable to the value gnu in order to compile with the vendor Fortran compiler and the GNU C/C++. This option is only supported for ESMF_ARCH=Darwin, ESMF_COMPILER=xlf, and ESMF_ARCH=Linux, ESMF_COMPILER=intel.

ESMF_C_LIBRARY Variable specifying which C/C++ libraries to link with. In most cases this should not be set; the default is to use the vendor-supplied libraries on those systems which normally come with a single development environment; on other systems like Linux clusters, the default is to use the ESMF_COMPILER setting. However, some vendor compilers support compiling with their compilers but linking with the GNU C/C++ libraries. In these cases, you can set this variable to the value gnu in order to link with the GNU C/C++ libraries. This option is only supported for ESMF_ARCH=Linux, ESMF_COMPILER=intel.

ESMF_EXHAUSTIVE Variable specifying how to compile the unit tests. If set to the value ON, then all unit tests will be compiled and will be executed when the test is run. If unset or set to any other value, only a subset of the unit tests will be included to verify basic functions. Note that this is a compile-time selection, not a run-time option.

ESMF_NO_IOCODE This version of the framework is prepared to use the netCDF I/O library. However, because the location of the library and include files varies widely from system to system the support for I/O is disabled by default. To enable support, edit build/common.mk and comment out the two lines which set ESMF_NO_IOCODE to ON and set the CPP flag, and recompile.

ESMF_PREC Variable specifying the size of an address on systems which can build either 32 or 64 bit executables. When possible the default value will be 64, otherwise it will be 32.

ESMF_SITE Build configure file site name or the value default. If not set, then the value of default is assumed.

On Alpha machines an additional environment variable needs to be set:

ESMF_PROJECT Load Sharing Facility (LSF) project name

On an Alpha machine, test and demo applications are run using the bsub command. The value of ESMF_PROJECT is used as the argument for bsub's -P option. The -P option assigns a job to a specific project.

Environment variables must be set in the user's shell and not inside an ESMF makefile or build system file. Here is an example of setting an environment variable in tcsh and csh shells:

```
setenv ESMF_PREC 32
```

In ksh shell environment variables are set this way:

```
export ESMF_PREC=32
```

Environment variables can also be set from the gmake command line:

```
gmake ESMF_PREC=32
```

6.2.3 Supported Platforms

The following two tables list various combinations of environment variable settings used by the ESMF build system. A `default` value in the compiler column indicates the vendor compiler.

The first table lists the exact combinations which are tested regularly and are fully supported. The second table lists all possible combinations which are included in the build system.

Fully tested combinations:

	ESMF_ARCH	ESMF_COMPILER	ESMF_COMM	ESMF_PREC
Alpha	OSF1	default	mpi	64
Cray X1	Unicos	default	mpi	64
IBM RS6000	AIX	default	mpi	32
IBM RS6000	AIX	default	mpi	64
Linux	Linux	absoft	mpich	32
Linux	Linux	intel	mpich	32
Linux	Linux	intel	lam	64
Linux	Linux	lahey	mpich	32
Linux	Linux	lahey	mpiuni	32
Linux	Linux	nag	mpich	32
Linux	Linux	pgi	mpich	32
Linux	Linux	pgi	mpiuni	32
Mac OS X	Darwin	absoft	lam	32
Mac OS X	Darwin	absoft	mpiuni	32
Mac OS X	Darwin	xlf	lam	32
Mac OS X	Darwin	xlf	mpiuni	32
SGI	IRIX64	default	mpi	32
SGI	IRIX64	default	mpi	64
SGI Altix	Linux	intel	mpi	64

All possible options, by platform/compiler. Where multiple options exist, the default value is in bold:

	ESMF_ARCH	ESMF_COMPILER	ESMF_COMM	ESMF_PREC
Alpha	OSF1	default	mpi , mpiuni	64
Cray X1	Unicos	default	mpi , mpiuni	64
IBM RS6000	AIX	default	mpi , mpiuni	32, 64
Linux	Linux	absoft	lam, mpich, mpiuni	32
Linux	Linux	intel	lam, mpi, mpich, mpiuni	32, 64
Linux	Linux	lahey	lam, mpich, mpiuni	32
Linux	Linux	nag	lam, mpich, mpiuni	32
Linux	Linux	pgi	lam, mpich, mpiuni	32
Mac OS X	Darwin	absoft	lam, mpich, mpiuni	32
Mac OS X	Darwin	nag	lam, mpich, mpiuni	32
Mac OS X	Darwin	xlf	lam, mpich, mpiuni	32
SGI	IRIX64	default	mpi , mpiuni	32, 64
SGI Altix	Linux	intel	mpi , mpiuni	64

Simultaneous multiple architecture builds are supported, with one restriction; the test cases may only be run on one platform at a time.

6.2.4 Building the ESMF Libraries

GNU make is required to build the library. On some systems this will be just the command `make`. On others it might be installed as `gmake` or even `gnumake`. In any event, use the `-version` option with the `make` command to determine if it is GNU make.

Build the library with the command:

```
gmake
```

or

```
gmake ESMF_BOPT=O
```

for an optimized version or

```
gmake ESMF_BOPT=g
```

for the debug version.

Build options that enable you to copy the library and `*.mod` files to specified directories are explained in Section 11.2.

Makefiles throughout the framework are configured to allow users to compile files only in the directory where `gmake` is entered. Shared libraries are rebuilt only if necessary. In addition the entire ESMF framework may be built from any directory by entering `gmake all`, assuming that all the environmental variables are set correctly as described in Section 6.2.2.

Users may also run examples or execute unit tests of specific classes by changing directories to the desired class `examples` or `tests` directories and entering `gmake run_examples` or `gmake run_tests`, respectively. For non-multiprocessor machines, uni-processor targets are available as `gmake run_examples_uni` or `gmake run_tests_uni`.

6.2.5 Building the ESMF Documentation

The documentation consists of an *ESMF User's Guide*, *ESMF Requirements Document*, and *ESMF Reference Manual for Fortran*. To build documentation:

```
gmake doc           ! Builds the manuals, including pdf and html.
```

The resulting documentation files will be located in the top level directory `$ESMF_DIR/doc`.

6.3 Using the ESMF

To use ESMF from Fortran, add the directory that contains the ESMF `*.mod` file(s),

```
$ESMF_DIR/mod/mod$ESMF_BOPT/$ESMF_ARCH.$ESMF_COMPILER.$ESMF_PREC.$ESMF_SITE
```

to your search path for `*.mod` files. For most compilers this path is identified either with a `-I` or a `-M`. You must also link with the ESMF library. For most compilers, adding the `-L` directory search flag with the following directory:

```
$ESMF_DIR/lib/lib$ESMF_BOPT/$ESMF_ARCH.$ESMF_COMPILER.$ESMF_PREC.$ESMF_SITE
```

followed by the `-lesmf` flag, will link in the ESMF library.

More details of how to link on specific platforms are included in the next section.

There is a single ESMF module, called `ESMF_Mod`, that should be included in applications with the Fortran `USE` statement. It is not necessary to include any header files in Fortran.

To use ESMF from C/C++, link with the ESMF library and include the `ESMC.h` file.

6.3.1 Shared Object Libraries

On some platforms, a shared object library is created in addition to the standard `.a` library. Shared object libraries are libraries that are loaded by the first program that uses them. All programs that start afterwards automatically use the existing shared library. The library is kept in memory as long as any active program is still using it.

Since shared object libraries are pre-linked to system libraries, using them simplifies life for the user when a variety of system libraries are required or when system libraries vary a great deal on a platform-to-platform basis. ESMF requires linking to both Fortran90 and C++ libraries on a set of very non-standardized platforms, and using shared objects helps to hide some of this complexity.

The order in which shared libraries are presented to the linker is important. Library routines must be called before they are defined. So, if a library **A** uses functionality provided by library **B**, then library **A** must appear before library **B** on the link line.

6.3.2 Linking

When building the ESMF libraries on platforms that support both 32 and 64 bit addressing, verify that the `ESMF_PREC` environment variable is set to match the compile option that was specified to build your application.

To link a Fortran application to the ESMF libraries please refer to the `link_rules` files found in the following directories:

```
$ESMF_DIR/build_config/AIX.default.default
$ESMF_DIR/build_config/IRIX64.default.default
$ESMF_DIR/build_config/Linux.intel.default
$ESMF_DIR/build_config/Linux.lahey.default
$ESMF_DIR/build_config/Linux.pgi.default
$ESMF_DIR/build_config/OSF1.default.default
```

In an effort to provide platform specific information for building ESMF and linking the libraries with your application, a SourceForge site, `esmcontrib`, has been created. To locate the platform makefiles for a specific institution, check out the `build_config_files` using the appropriate `CVSROOT`. The URL for the `esmcontrib` SourceForge site is:

<http://sourceforge.net/projects/esmfcontrib/>

Additionally, you may check out all the platform makefile fragments for a particular institution from the `esmcontrib` site. For example, to check out the available makefile fragments for platforms at the National Center for Atmospheric Research, `ncar`, change directories to

```
$ESMF_DIR/build_config
```

and use the following CVS command:

```
cvs -z3 -d:ext:$username@cvs.sourceforge.net:/cvsroot/esmfcontrib checkout ncar
```

The following directories will be checked out:

```
AIX.default.blackforest
AIX.default.bluesky
Linux.lahey.longs
```

To build using these makefiles you must set the environment variable `ESMF_SITE` to `blackforest`, `bluesky`, or `longs`.

At the present time, we have files for the following institutions:

anl - Argonne National Laboratory
cola - Center for Ocean-Land-Atmosphere Studies
gsfc - Goddard Space Flight Center
ncar - National Center for Atmospheric Research

Users are encouraged to contribute pertinent information to the `esmcontrib` repository.

6.4 Demonstration Application

The `ESMF_COUPLED_FLOW` demonstration illustrates use of both the ESMF infrastructure and superstructure. It is described in detail in Section 8.

6.4.1 Running the Demonstration

To run the `ESMF_COUPLED_FLOW` demo starting from ESMF source code, type

```
gmake ESMF_COUPLED_FLOW
```

or

```
gmake ESMF_COUPLED_FLOW_uni
```

from the `$ESMF_DIR` directory. This will compile both the ESMF library and the demo and then run the demo.

To simply run the demo, type:

```
gmake run_demos
```

or

```
gmake run_demos_uni
```

7 Architectural Overview

The ESMF architecture is characterized by the layering strategy shown in Figure 1. User code components that implement the *science* portions of an application, for example a sea ice or land model, are sandwiched between two layers. The upper layer is denoted the **superstructure** layer and the lower layer the **infrastructure** layer. The role of the superstructure layer is to provide a shell which encompasses user code and provides a context for interconnecting input and output data streams between components. The key elements of the superstructure are described in Section 7.2. These elements include classes that wrap user code, ensuring that all components present consistent interfaces. The infrastructure layer provides a foundation that developers of science components can use to speed construction and to ensure consistent, guaranteed behavior. The elements of the infrastructure include constructs to support parallel processing with data types tailored to Earth science applications, specialized libraries to support consistent time and calendar management and performance, error handling and scalable I/O tools. The infrastructure layer is described in Section 7.3. A hierarchical combination of superstructure, user code components, and infrastructure are joined together to form an ESMF application.

7.1 Key Concepts

The ESMF architecture and programming paradigm are based upon five key concepts: modularity, flexibility, hierarchical organization, communication within components, and a uniform communication API.

7.1.1 Modularity

The ESMF design is based upon modular components. There are two types of components, one of which represents models (Gridded Components) and one which represents couplers (Coupler Components). Data are always passed between components using a data structure called a State, which can store Fields, Bundles of Fields, Arrays, and other States. A Gridded Component stores no information about the internals of the Gridded Components that it interacts with; this information is passed in through the argument lists of its initialize, run, and finalize methods. The information that is passed in through the argument list can be a State from another Gridded Component, or it can be a function pointer that performs a computation or communication on a State. These function pointers (not yet implemented) are called Transforms, and they are created by Coupler Components. They are called inside the Gridded Component they are passed into. Although Transforms add some complexity to the framework (and their use is not required), they are what will enable ESMF to accommodate virtually any model of communication between components.

Modularity means that an ESMF component stores nothing about the internals of other components. This allows components to be used more easily in multiple contexts.

7.1.2 Flexibility

The ESMF does not dictate how models should be coupled; it simply provides tools for creating couplers. For example, both a hub-and-spokes type coupling strategy and pairwise strategies are supported. The ESMF also allows model communications to occur mid-timestep, if desired. Sequential, concurrent, and mixed modes of execution are supported.

The ESMF does not impose restrictions on how data flows through an application. This accommodates scientific innovation - if you want your atmospheric model to communicate with your sea ice model mid-timestep, ESMF will not stop you.

7.1.3 Hierarchical Organization

The ESMF allows applications to be composed hierarchically. For example, physics and dynamics modules can be defined as separate Gridded Components, coupled together with a Coupler Component, and all of these nested within a single atmospheric Gridded Component. The atmospheric Gridded Component can be run standalone, or can be included in a larger climate or data assimilation application. See Figure 2 for an illustrative example.

The data structure that enables scalability in ESMF is the derived type Gridded Component. Fortran alone doesn't allow you to create generic components - you'd have to create derived types for PhysComp, and DynComp, and PhysDynCouplerComp, and AtmComp. In ESMF, these are always of type GridComp or CplComp, so they can be called by the same drivers (whether that driver is a standard ESMF driver or another model), and use the same methods without having to overload them with many specific derived types. It's the same idea when you want to support different implementations of the same component, like multiple dynamics.

The ESMF defines a hierarchical, scalable architecture that is natural for organizing very complex applications, and for allowing exchangeable components.

7.1.4 Communication Within Components

Communication in ESMF always occurs within a component. It can occur internal to a Gridded Component, and have nothing to do with interactions with other components (setting aside synchronization issues), or it can occur within a Coupler Component or a Transform generated by a Coupler Component. A result of the rule that all communication happens within a component is that Coupler Components must always be defined on the union of all the components that they couple together. Models can choose to use whatever mechanism they want for intra-model communications.

The point is that although the ESMF defines some simple rules for communication, the communication mechanism that the framework uses is not hardwired into its architecture - the sends and receives or puts and gets are enclosed within Gridded Components, Coupler Components and Transforms. The intent is to accommodate multiple models of communication and technical innovations.

Figure 2: A typical building block for an ESMF application consists of a parent Gridded Component, two or more child Gridded Components, and a Coupler Component. The parent Gridded Component is called by an Application Driver. All ESMF components have initialize, run, and finalize methods. The diagram shows that when the Application Driver calls initialize on a parent Gridded Component, the call cascades down to all of its children, so that the result is that the entire “tree” of components is initialized. The run and finalize methods work the same way. In this example a hurricane simulation is built from ocean and atmosphere Gridded Components. The data exchange between the ocean and atmosphere is handled by an ocean-atmosphere Coupler Component. Since the whole hurricane simulation is a Gridded Component, it could be easily be treated as a child and coupled to another Gridded Component, rather than being driven directly by the Application Driver. A similar diagram could be drawn for an atmospheric model containing physics and dynamics components, as described in Section 7.1.3.

7.1.5 Uniform Communication API

ESMF is developing a single API for shared and distributed memory that, unlike MPI, accounts for NUMA architectures and does not treat all processes as being identical. It's possible for users to set ESMF communications to a strictly message passing mode and put in their own OpenMP commands.

The goal is to create a programming paradigm that is performance sensitive to the architecture beneath it without being discouragingly complicated.

7.2 Superstructure

The ESMF superstructure layers in an application furnish a unifying context within which user components are interconnected. Classes called **Gridded Components**, **Coupler Components**, and **States** are used within the superstructure to achieve this flexibility. We describe these classes below:

7.2.1 Import and Export State Classes

User code components under ESMF use special interface objects for component to component data exchanges. These objects are of type import State and export State. These special types support a variety of methods that allow user code components to, for example, fill an export State object with data to be shared with other components or query an import State object to determine its contents. In keeping with the overall requirements for high-performance it is permitted for import State and export State contents to use references or pointers to component data, so that costly data copies of potentially very large data structures can be avoided where possible. The content of an import State and an export State can be made self-describing.

7.2.2 Interface Standards

The import State and export State abstractions are designed to be flexible enough so that ESMF does not need to mandate a single format for fields. For example, ESMF does not prescribe the units of quantities exported or imported; instead it provides mechanisms to describe units, memory layout, and grid coordinates. This allows the ESMF software to support a range of different policies for physical fields. The interoperability experiments that we are using to demonstrate ESMF make use of the emerging CF conventions [1] for describing physical fields. This is a policy choice for that set of experiments. The ESMF software itself can support arbitrary conventions for labeling and characterizing the contents of States.

7.2.3 Gridded Component Class

The Gridded Component class describes a user component that takes in one import State and produces one export State. Examples of Gridded Components are major Earth system model components such as land surface models, ocean models, atmospheric models and sea ice models. Components used for linear algebra manipulations in a state estimation or data assimilation optimization procedure are also created as Gridded Components. In general the fields within an import State and export State of a Gridded Component will use the same discrete grid.

7.2.4 Coupler Component Class

The other top-level component class supported in the ESMF architecture is a Coupler Component. This class is used for components that take one or more import States as input and map them through spatial and temporal interpolation or extrapolation onto one or more output export States. In a Coupler Component it is often the case that the export State(s) is on a different discrete grid to that of the import State(s). For example, in a coupled ocean-atmosphere simulation a Coupler Component might be used to map a set of sea-surface fields in an ocean model to appropriate planetary boundary layer fields in an atmospheric model.

Figure 3: ESMF supports configurations with a single central Coupler Component. In this case inputs from all Gridded Components are transferred and regridded through the central coupler.

7.2.5 Flexible Data and Control Flow

Import States, export States, Gridded Components and Coupler Components can be arrayed flexibly within a superstructure layer. Using these constructs it is possible to configure a set of components with multiple pairwise Coupler Components, Figure 4. It is also possible to configure a set of concurrently executing Gridded Components joined through a single Coupler Component of the style shown in Figure 3.

The set of superstructure abstractions allows flexible data flow and control between components. However, components will often use different discrete grids, and time-stepping components may march forward with different time intervals. In a parallel compute environment different components may be distributed in a different manner on the underlying compute resources. The ESMF infrastructure layer provides elements to manage this complexity.

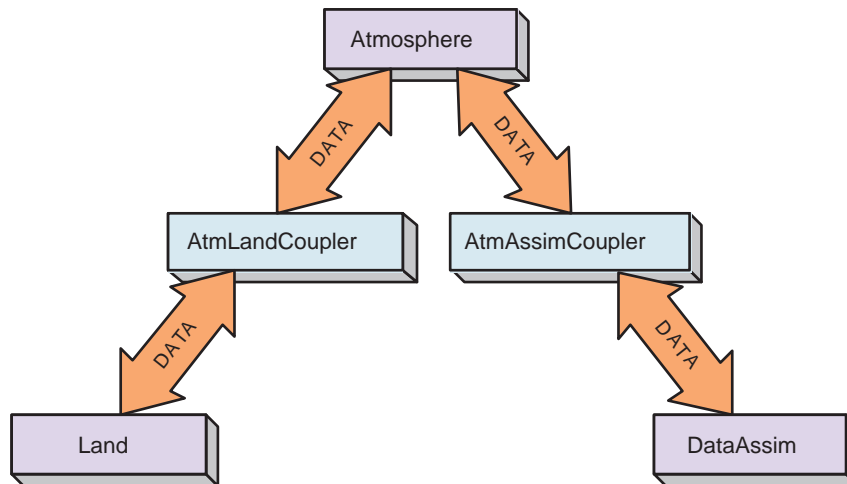

7.3 Infrastructure

Figure 5 illustrates three Gridded Components, each with a different grids, being coupled together. In order to achieve this coupling several steps beyond defining import State and export State objects to act as data conduits are required. Coupler Components are needed that can interpolate between the different grids. The necessary transformations may also involve mapping between different units and/or memory layout conventions for the fields that pass between components. In a parallel compute environment the Coupler Components may also be required to map between different domain decompositions. In order to advance in time correctly the separate Gridded Components must have compatible notions of time. Approaches to parallelism within the Gridded Components must also be compatible. The **Infrastructure** layer contains a set of classes that address these issues and assist in managing overall system complexity. We describe these classes below:

7.3.1 Bundle, Field and Array Classes

Bundle, Field and Array classes contain data together with descriptive physical and computational attribute information. The physical attributes include information that describes the units of the data. The computational attributes include information on the layout in memory of the field data. The Field class is primarily geared toward structured

Figure 4: ESMF also supports configurations with multiple point to point Coupler Components. These take inputs from one Gridded Component and transfer and regrid the data before passing it to another Gridded Component. This schematic shows a flow of data between two Coupler Components that connect three Gridded Components: an atmosphere model with a land model, and the same atmosphere model with a data assimilation system.

data. A comparable class called Location Stream, not yet implemented, will provide a self-describing container for unstructured observational data streams.

7.3.2 Grid Class

The *Grid* class is an extensible class that holds discrete grid information. It has subtypes that allow it to serve as a container for the full range of different physical grids that might arise in a coupled system. In the example in figure 5 objects of type *Grid* would hold grid information for each of the spectral grid, the latitude-longitude grid, the mosaic grid and the catchment grid.

The *Grid* class is also used to represent the decomposition of a data structure into subdomains, typically for parallel processing purposes. The class is designed to support a generalized “ghosting” for tiled decompositions of finite difference, finite volume and finite element codes.

7.3.3 Time and Calendar Management Class

To support synchronization between components Time, Time Interval, Calendar, Clock, and Alarm classes are provided. These classes allow Gridded and Coupler Component processing to be latched to a common controlling clock, and to schedule notification of regular events (such as a coupling intervals) and unique events.

7.3.4 I/O Classes

The infrastructure layer defines a set of *I/O* classes for storing and retrieving Field and Grid information to and from persistent storage. Currently the *I/O* classes support a netCDF format.

Figure 5: Schematic showing the coupling of components that use different discrete grids and different time-stepping. In this example, component *NCAR Atmosphere* might use a spectral grid based on spherical harmonics, component *GFDL Ocean* might use a latitude-longitude grid but with a patched decomposition that does not include land masses and component *NSIPP Land* might use a mosaic-based grid for representing vegetation patchiness and a catchment area based grid for river routings. The ESMF infrastructure layer contains tools to help develop software for coupling between components on different grids, mapping between components with different distributions in a multi-processor compute environment and synchronizing events between components with different time-stepping intervals and algorithms.

7.3.5 DELayout and Virtual Machine

To provide a mechanism for ensuring performance portability ESMF defines DELayout and Virtual Machine classes. These classes provide a set of high-level platform independent interfaces to performance critical parallel processing communication routines. These routines can be tuned to specific platforms to ensure optimal parallel performance on many platforms.

7.3.6 Logging and Error Handling

The LogErr class is designed to aid in managing the complexity of multi-component applications. It provides ESMF with a unified mechanism for managing logs and error reporting.

8 ESMF_COUPLED_FLOW Demonstration Program

8.1 Introduction

This section describes the organization of a demonstration program which uses the ESMF Framework, including use of both the Superstructure and Infrastructure.

8.2 ESMF_COUPLED_FLOW Description

The ESMF_COUPLED_FLOW application is comprised of two ESMF Gridded Components and a Coupler Component. The first Gridded Component, FlowSolver, solves the compressible time-dependent fluid flow equations. The algorithm applies an explicit solution technique to a staggered, Arakawa C grid that is cartesian and uniform. State variables, including density, pressure, viscosity and temperature, are located at cell-centers, while velocities are located at cell faces. This component is initialized with a steady-state, one-dimensional flow. The second Gridded Component, Injector, injects fluid into the first normal to the flow along one of the boundaries. The injected fluid can have arbitrary velocity, temperature, density and duration, effectively setting some of the boundary conditions for the first component. The FlowSolver and Injector Components sit on different cartesian grids. The Coupler Component redistributes boundary condition data from the Injector to the FlowSolver.

9 Program Organization

The demonstration program consists of a top level Application Driver, a top level Gridded Component, and nested within this Gridded Component are 3 subcomponents: a Coupler Component and 2 Gridded Components.

The following diagram shows this organization. Note that there is no direct communication between the subcomponents; all interactions are mediated by the top level Gridded Component.

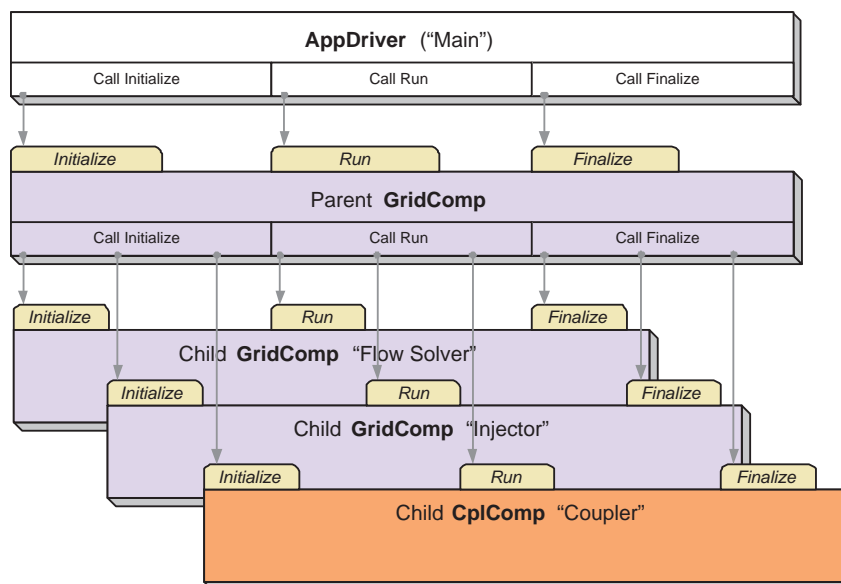

Each component communicates via Initialize, run, and finalize subroutine calls. These go through the ESMF where they are checked for validity, default values are supplied, and only those components involved in the computation are invoked.

10 Framework Usage Details

10.1 Fortran: Module Interface CoupledFlowApp.F90 - Main program source file for demo (Source File: CoupledFlowApp.F90)

ESMF Application Wrapper for Coupled Flow Demo. This file contains the main program, and creates a top level ESMF Gridded Component to contain all other Components.

Figure 6: Structure of the demonstration program.

10.1.1 Namelist Input Parameters for CoupledFlowApp:

The following variables must be input to the CoupledFlow Application to run. They are located in a file called "coupled_app_input."

The variables are:

- i_max** Global number of cells in the first grid direction.
- j_max** Global number of cells in the second grid direction.
- x_min** Minimum grid coordinate in the first direction.
- x_max** Maximum grid coordinate in the first direction.
- y_min** Minimum grid coordinate in the second direction.
- y_max** Maximum grid coordinate in the second direction.
- s_month** Simulation start time month (integer).
- s_day** Simulation start time day (integer).
- s_hour** Simulation start time hour (integer).
- s_min** Simulation start time minute (integer).
- e_month** Simulation end time month (integer).
- e_day** Simulation end time day (integer).
- e_hour** Simulation end time hour (integer).
- e_min** Simulation end time minute (integer).

10.1.2 Example of Initializing the Framework:

The first call to ESMF must be the initialize method. As part of initialization the default Calendar can be specified, some options for logging can be set, and the default global VM can be returned. Here we are setting the default Calendar to be Gregorian, and getting back the global VM:

```
! Initialize ESMF, get the default Global VM, and set
! the default calendar to be Gregorian.
call ESMF_Initialize(vm=vm, defaultCalendar=ESMF_CAL_GREGORIAN, rc=rc)

! Create the top level Gridded Component, passing in the default VM.
compGridded = ESMF_GridCompCreate(vm, "Coupled Flow Demo", rc=rc)
```

10.1.3 Example of Calendar and Clock Creation and Usage:

The following piece of code provides an example of Clock creation used in the Demo. Note that the Gregorian calendar was set as the default in the ESMF_Initialize() call above. As shown in this example, we first initialize a time interval (timestep) to 2 seconds:

```
call ESMF_TimeIntervalSet(timeStep, s=2, rc=rc)
```

And then we set the start time and stop time to input values for the month, day, and hour (assuming the year to be 2003):

```
call ESMF_TimeSet(startTime, yy=2003, mm=s_month, dd=s_day, &
                  h=s_hour, m=s_min, s=0, rc=rc)

call ESMF_TimeSet(stopTime, yy=2003, mm=e_month, dd=e_day, &
                  h=e_hour, m=e_min, s=0, rc=rc)
```

With the time interval, start time, and stop time set above, the Clock can now be created:

```
clock = ESMF_ClockCreate(timeStep=timeStep, startTime=startTime, &
                        stopTime=stopTime, rc=rc)
```

Subsequent calls to ESMF_ClockAdvance with this clock will increment the current time from the start time by the timestep.

10.1.4 Example of Grid Creation:

The following piece of code provides an example of Grid creation used in the Demo. The extents of the Grid were previously read in from an input file, but the rest of the Grid parameters are set here by default. The Grid spans the Application's PET list, while the type of the Grid is assumed to be horizontal and cartesian x-y with an Arakawa C staggering. The Grid name is set to "source grid":

```
counts(1) = i_max
counts(2) = j_max
g_min(1) = x_min
g_min(2) = y_min
g_max(1) = x_max
g_max(2) = y_max
grid = ESMF_GridCreateHorzXYUni(counts=counts, &
```

```

        minGlobalCoordPerDim=g_min, &
        maxGlobalCoordPerDim=g_max, &
        horzStagger=ESMF_GRID_HORZ_STAGGER_C_NE, &
        name="source grid", rc=rc)
call ESMF_GridDistribute(grid, delayout=DELayoutTop, rc=rc)

```

The Grid can then be attached to the Gridded Component with a set call:

```
call ESMF_GridCompSet(compGridded, grid=grid, rc=rc)
```

10.2 Fortran: Module Interface CoupledFlowDemo.F90 - Top level Gridded Component source (Source File: CoupledFlowDemo.F90)

ESMF Coupled Flow Demo - A Gridded Component which can be called either directly from an Application Driver or nested in a larger application. It contains 2 nested subcomponents and 1 Coupler Component which does two-way coupling between the subcomponents.

10.2.1 Example of Set Services Usage:

The following code registers with ESMF the subroutines to be called to Init, Run, and Finalize this component.

```

! Register the callback routines.

call ESMF_GridCompSetEntryPoint(comp, ESMF_SETINIT, &
                                coupledflow_init, ESMF_SINGLEPHASE, rc)
call ESMF_GridCompSetEntryPoint(comp, ESMF_SETRUN, &
                                coupledflow_run, ESMF_SINGLEPHASE, rc)
call ESMF_GridCompSetEntryPoint(comp, ESMF_SETFINAL, &
                                coupledflow_final, ESMF_SINGLEPHASE, rc)

```

10.2.2 Example of Component Creation:

The following code creates 2 Gridded Components on the same set of PETs (persistent execution threads) as the top level Component, but each of the Grids used by these Components will have a different connectivity. It also creates a Coupler Component on the same PET set.

```

cnameIN = "Injector model"
INcomp = ESMF_GridCompCreate(vm, cnameIN, rc=rc)

cnameFS = "Flow Solver model"
FScomp = ESMF_GridCompCreate(vm, cnameFS, rc=rc)

cplname = "Two-way coupler"
cpl = ESMF_CplCompCreate(vm, cplname, rc=rc)

```

10.2.3 Example of State Creation:

The following code creates Import and Export States for the Injection subcomponent. All information being passed between subcomponents will be described by these States.

```
INimp = ESMF_StateCreate("Injection Input", ESMF_STATE_IMPORT, rc=rc)
INexp = ESMF_StateCreate("Injection Feedback", ESMF_STATE_EXPORT, rc=rc)
```

10.3 Fortran: Module Interface FlowSolverMod.F90 - Source file for Flow Solver Component (Source File: FlowSolverMod.F90)

This component does a finite difference solution of the PDE's for semi-compressible fluid flow. It uses an explicit solution method on a staggered mesh with velocities and momentum located at cell faces and other physical quantities at cell centers. The component assumes a logically rectangular two-dimensional cartesian mesh with constant cell spacing. It also employs a donor-cell advection scheme. Although the algorithm is general, the boundary conditions are coded to assume constant inflow on the left, outflow on the right, and free-slip insulated boundaries on the top and bottom. This component will allow the user to construct flow obstacles with different energies, and it accepts a second inflow from the bottom boundary that can be controlled by a second component. For material properties, this component uses an ideal gas equation of state, and assumes constant ratio of specific heats, thermal conductivity, and specific heat capacity. There is no system of units assumed by the component – it is up to the user to ensure dimensional consistency.

The following are the semi-compressible flow equations used in this component.

$$\frac{\partial \rho}{\partial t} + \frac{\partial \rho u}{\partial x} + \frac{\partial \rho v}{\partial y} = 0$$

$$\frac{\partial \rho u}{\partial t} + \frac{\partial \rho u^2}{\partial x} + \frac{\partial \rho uv}{\partial y} = -\frac{\partial(p+q)}{\partial x}$$

$$\frac{\partial \rho v}{\partial t} + \frac{\partial \rho uv}{\partial x} + \frac{\partial \rho v^2}{\partial y} = -\frac{\partial(p+q)}{\partial y}$$

$$\frac{\partial pI}{\partial t} + \frac{\partial \rho u I}{\partial x} + \frac{\partial \rho v I}{\partial y} = -(p+q) \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \frac{k}{b} \left(\frac{\partial^2 I}{\partial x^2} + \frac{\partial^2 I}{\partial y^2} \right)$$

$$p = (\gamma - 1)\rho I$$

$$q = -q_o \rho u_{in} (dx^2 + dy^2)^{1/2} \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right)$$

$$if q < 0 set q = 0$$

ρ density
 t time
 u x-component of velocity
 v y-component of velocity
 p pressure

Where q artificial velocity
 I standard internal energy

γ ratio of specific heats
 k thermal conductivity
 b specific heat capacity
 q_o artificial viscosity coefficient, dimensionless
 u_{in} inflow velocity (representative velocity)

10.3.1 Namelist Input Parameters for Flowsolver:

The following variables must be input to the FlowSolver Component to run. They are located in a file called "coupled_flow_input."

The variables are:

uin Inflow velocity at left boundary.

rhoin Inflow density at left boundary.

siein Inflow specific internal energy at left boundary.

gamma Ratio of specific heats for the fluid (assumed constant).

akb Thermal conductivity over specific heat capacity (assumed constant).

q0 Dimensionless linear artificial viscosity coefficient (should be between 0.1 and 0.2).

u0 Initial velocity in the first grid direction.

v0 Initial velocity in the second grid direction.

sie0 Initial specific internal energy.

rho0 Initial density.

printout Number of cycles between graphical output files.

sieobs Specific internal energy of the obstacles.

nobsdesc Number of obstacle descriptors. Each descriptor defines a block of cells that will serve as an obstacle and not allow fluid flow.

iobs_min Minimum global cell number in the first grid direction defining a block of cells to be an obstacle. Must be [nobsdesc] number of these.

iobs_max Maximum global cell number in the first grid direction defining a block of cells to be an obstacle. Must be [nobsdesc] number of these.

jobs_min Minimum global cell number in the second grid direction defining a block of cells to be an obstacle. Must be [nobsdesc] number of these.

jobs_max Maximum global cell number in the second grid direction defining a block of cells to be an obstacle. Must be [nobsdesc] number of these.

iflo_min Minimum global grid cell number for the second inflow along the bottom boundary.

iflo_max Maximum global grid cell number for the second inflow along the bottom boundary.

10.3.2 Example of FieldHalo Usage:

The following piece of code provides an example of haloing the data in a Field. Currently the Field halo routine assumes the entire halo is updated completely; i.e. the user cannot specify halo width or side separately. Field halo uses a Route object to transfer data from the exclusive computational domain of one DE to the halo region of another.

```
call ESMF_FieldHalo(field_rhou, rc=status)
if(status .NE. ESMF_SUCCESS) then
  print *, "ERROR in FlowRhoVel: rhou halo"
  return
endif
```

10.4 Fortran: Module Interface FlowArraysMod.F90 - Source file for Data for Flow Solver (Source File: FlowArraysMod.F90)

Allocate and deallocate ESMF objects which handle data arrays including ESMF_Fields, ESMF_Grids, and ESMF_Arrays.

10.4.1 Example of Field Creation and Array Usage:

The following piece of code provides an example of Field creation used in the demo. In this example we create a Field from an ArraySpec, which designates the rank, type, and kind of the data. First initialize the ArraySpec with rank 2 for a two-dimensional array, type ESMF_DATA_REAL, and kind ESMF_KIND_R4:

```
call ESMF_ArraySpecSet(arrayspec, rank=2, type=ESMF_DATA_REAL, &
                      kind=ESMF_R4)
```

Next, create a Field named "SIE" using the ArraySpec with a relative location (relloc) at the cell centers:

```
field_sie = ESMF_FieldCreate(grid, arrayspec, horzRelloc=ESMF_CELL_CENTER, &
                             haloWidth=haloWidth, name="SIE", rc=status)
```

Once the Field has been created, we get a pointer to the Array data (the Fortran 90 array), and call it "sie". Inside the Component "sie" can be used like an array made by an F90 allocation but will reference the data inside "field_sie."

```
call ESMF_FieldGetDataPointer(field_sie, sie, ESMF_DATA_REF, rc=status)
```

10.5 Fortran: Module Interface CouplerMod.F90 - Source for 2-way Coupler Component (Source File: CouplerMod.F90)

The Coupler Component provides two-way coupling between the Injector and FlowSolver Models. During initialization this Component is responsible for setting that data "is needed" from the export state of each model. In its run routine it calls route to transfer the needed data directly from one Component's export state to the other Component's import state.

10.5.1 Example of Redist Usage:

The following piece of code provides an example of calling the data redistribution routine between two Fields in the Coupler Component. Unlike regrid, which translates between different Grids, redistrib translates between different DELayouts on the same Grid. The first two lines get the Fields from the States, each corresponding to a different subcomponent. One is an Export State and the other is an Import State.

```
call ESMF_StateGetField(importState, datanames(i), srcfield, rc=rc)
call ESMF_StateGetField(exportState, datanames(i), dstfield, rc=rc)
```

The redistrib routine uses information contained in the Fields and the Coupler VM object to call the communication routines to move the data. Because many Fields may share the same Grid association, the same routing information may be needed repeatedly. Route information is saved so the precomputed information can be retained. The following is an example of a Field redistrib call:

```
call ESMF_FieldRedist(srcfield, dstfield, routehandle, rc=rc)
```

10.6 Fortran: Module Interface InjectorMod - Fluid Injection Component (Source File: InjectorMod.F90)

This is a user-supplied fluid injection component which interacts with a separate fluid flow model component by altering the inflow boundary conditions during a user-specified time interval. The energy, velocity, and density of the inflow fluid during the injection time interval are user-specified. The location of the inflow is determined by the fluid

flow model component through a set of boundary condition flags which are supplied to this component in the import state. The energy, velocity, and density fields of the calculation are updated by this component and returned to the fluid flow solver for the next computational time step in the export state.

10.7 Namelist Input Parameters for Injector:

The following variables must be input to the Injector Component to run. They are located in a file called "coupled_inject_input."

The variables are:

on_month Injector start time month (integer).

on_day Injector start time day (integer).

on_hour Injector start time hour (integer).

on_min Injector start time minute (integer).

off_month Injector stop time month (integer).

off_day Injector stop time day (integer).

off_hour Injector stop time hour (integer).

off_min Injector stop time minute (integer).

in_energy Standard internal energy of the injector flow.

in_velocity Vertical velocity of the injector flow.

in_rho Density of the injector flow.

11 Building and Validating the ESMF

11.1 Make System

For most users the description of the build system in previous sections should be sufficient. Some users, however, may wish to have a more detailed knowledge of the make system either for configuring different build options or for porting to unsupported platforms.

11.1.1 General Structure

The ESMF build system is divided into two parts. The first is the series of makefiles located with the source code. The second is a set of makefile fragment files designed to be used by the source code makefiles. Makefile fragment files are files that contain makefile syntax defining build rules and actions, but do not constitute a complete build system.

The main components of the make system are:

- **Build directories**

There are two directories containing makefile fragment files used by the make system.

The `build` directory contains the generic makefile fragment file `common.mk` that is included by the top level makefile in the source tree. `common.mk` contains generic build system settings and build rules used across all platforms. A user should have no reason to edit `common.mk`.

The `build_config` directory contains makefile fragments for each supported platform defining compilers, compiler flags, and the various other definitions that are necessary to build on each platform. Files can also be added to this directory for specific machines where the build settings are different from the standards of the architecture. One of the files in this directory will be included by the `build/common.mk` file depending the values of the environment variables `ESMF_ARCH`, `ESMF_COMPILER` and `ESMF_SITE`. See below for more details on environment variables.

- **Environment Variables**

The three sets of source codes that the build system supports all need environment variables set to point to their top level source code directories.

ESMF Library

To build the ESMF library, `ESMF_DIR` needs to be set to the top level ESMF library source code directory.

Implementation Report

The build system needs `ESMF_IMPL_DIR` set to the top level source code directory of the Implementation Report source tree to build the report and to build and run the examples.

EVA Applications

An EVA source code tree does not contain a copy of the ESMF build system. Instead it uses a copy found in an ESMF library source code tree. Building the EVA applications requires that `ESMF_EVA_DIR` and `ESMF_DIR` be set. `ESMF_EVA_DIR` has to be set to the top directory of the EVA source code. `ESMF_DIR` has to be set to the top directory of an ESMF source code tree.

There are several other variables that the build system uses. If they are not set, then the build system will assign default values to them. In most cases the default values will be fine.

ESMF_ARCH

Defines the current architecture. Default value is the value returned by the command `uname -s`. There should be almost no reason for `ESMF_ARCH` to be set by a user.

ESMF_BOPT

Variable specifying that the build system use either debugging or optimization options. Value of `g` specifies the debugging options. Value of `O` (capital oh) specifies optimization options. Default value is `O`.

ESMF_COMM

Defines which MPI communications library to use. Many times a machine will come with its own MPI library and in those cases the default setting will be `mpi`. Otherwise the default setting will be `mpiuni` so that the `mpiuni` library will be used. This is the case for Linux and Darwin systems. Other possible settings are `mpich` and `lam`.

ESMF_COMPILER

Variable specifying which compiler to use. Value can be `default`, `absoft`, `intel`, `lahey`, `nag`, `pgi`, or `xf`. If the value is `default` or the `ESMF_COMPILER` is left unset, then the default compiler will be used. On systems which usually come with a single vendor-supplied compiler, the default is to use this compiler. On systems like Linux clusters where there is no single vendor compiler installed on all systems, you will generally want to set this. The default for Linux systems is `lahey` and on Darwin (Mac OS X) systems it is `absoft`.

ESMF_C_COMPILER

Variable specifying which C/C++ compiler to use. In most cases this should not be set; the default is to use the vendor-supplied compilers on those systems which normally come with a single development environment; on other systems like Linux clusters, the default is to use the `ESMF_COMPILER` setting. However, some Fortran compilers support linking with C and C++ code compiled with the GNU compilers; in these cases, you can set this variable to the value `gnu` in order to compile with the vendor Fortran compiler and the GNU C/C++. This option is only supported for `ESMF_ARCH=Darwin`, `ESMF_COMPILER=xf`, and `ESMF_ARCH=Linux`, `ESMF_COMPILER=intel`.

ESMF_C_LIBRARY

Variable specifying which C/C++ libraries to link with. In most cases this should not be set; the default is to use the vendor-supplied libraries on those systems which normally come with a single development environment; on other systems like Linux clusters, the default is to use the ESMF_COMPILER setting. However, some vendor compilers support compiling with their compilers but linking with the GNU C/C++ libraries. In these cases, you can set this variable to the value `gnu` in order to link with the GNU C/C++ libraries. This option is only supported for ESMF_ARCH=Linux, ESMF_COMPILER=intel.

ESMF_EXHAUSTIVE

The unit tests by default compile only a subset of the unit tests. If ESMF_EXHAUSTIVE is set to the value `ON`, then when compiling the unit tests, all tests will be included. Note that this is a compile time, not run time, option.

ESMF_NO_IOWCODE

The current release of the system is prepared to link with the `netCDF` I/O libraries, but since the installation of the libraries and include files varies widely from system to system support for them is disabled by default. To enable I/O support, edit the `build/common.mk` file and comment out the setting of both the `CPPFLAG` and environment variable. Additional customization will be needed in the `build_config` makefile fragments to point the framework to the location of the include and library files.

ESMF_PREC

Variable specifying the size of an address on systems which can build either 32 or 64 bit executables. When possible the default value will be 64, otherwise it will be 32.

ESMF_SITE

If ESMF_SITE is not set or has the value of default, default build settings for the current machine architecture and compiler will be used. Values are created from the user's site.

• Makefiles

Every source tree contains a makefile in its top level directory. This makefile includes the `common.mk` file from the `build` directory. The top level makefile contains makefile settings specific for the source code that it is found in.

Each directory in the source tree contains a makefile which includes the top level makefile. These local makefiles include definitions that allow the local files and documents to be built.

11.1.2 Build Configuration

A single makefile or makefile fragment from the build system never constitutes a complete set of build rules and settings. Starting from the local makefile, successive include commands are used to string together makefiles and makefile fragments to create a complete system of build rules and settings. Configuration of the build system is done by including a configuration makefile fragment. The build system can be configured for a machine's architecture or, if needed, for a particular machine and its compiler. A configuration for a specific machine or compiler is referred to as a site configuration.

The string of files included is fairly short. Makefiles below the top level makefile include the top level makefile. The top level makefile includes `build/common.mk` and then `build/common.mk` includes a configuration file from the `build_config` directory. The configuration files in the `build_config` directory contain the architecture and site specific build settings. The architecture, compiler and site that a file configures is determined by its name. The configuration makefile fragments follow this naming convention:

```
ESMF_ARCH.ESMF_COMPILER.ESMF_SITE/build_rules.mk
```

Where ESMF_ARCH, ESMF_COMPILER, and ESMF_SITE are environment variables either set by the user or given default values by the build system. ESMF_ARCH is the current architecture and will have the value returned by the command `uname -s`. ESMF_COMPILER is the compiler name. ESMF_SITE is the current machine name. If there are no site specific files for a particular architecture, then ESMF_COMPILER and ESMF_SITE will be set to default values. Examples:

```
AIX.default.default/build_rules.mk      ! Default configuration for RS6000.  
Linux.lahey.default/build_rules.mk      ! Linux configuration using lahey compilers.
```

11.1.3 Source Code Configuration

C++ and C source code written to build on a range of platforms many times require preprocessor directives to configure the source code for specific platforms. The directives are included in the source code and are processed by the C preprocessor (cpp) before the source code is compiled. The directives are used to determine among other things, the memory requirements of variable types and the system resources that are available.

The ESMF build system provides preprocessor directives in `ESMC_Conf.h` and `ESMF_Conf.inc` files that are included in the source code. The path to these files is

```
build_config/ESMF_ARCH.ESMF_COMPILER.ESMF_PREC.ESMF_SITE
```

Where `ESMF_ARCH`, `ESMF_COMPILER`, `ESMF_PREC` and `ESMF_SITE` are environment variables set by the user or given default values by the build system. Based on the settings of these environment variables, the build system provides a path to the correct files during source code compiles.

11.1.4 Building on New Platforms

The build system can be ported to other Unix platforms by adding new makefile fragments and configuration files. The new makefile fragment file has to follow the naming convention used by the existing makefile fragment files and be created in the directory `build_config`. The new file will also have to define the same makefile variables as the existing makefile fragment files.

Porting to a new machine will require new configuration files as well. New configuration files have to define the same machine attributes as existing configuration files. Example:

```
build_config/Linux.pgi.mysite/build_rules.mk  
build_config/Linux.pgi.mysite/ESMF_Conf.inc  
build_config/Linux.pgi.mysite/ESMC_Conf.h
```

11.2 Install Options

There is an `install` target which will copy the library and `*.mod` files to specified directories. To invoke this target use:

```
gmake ESMF_BOPT=[O,g] ESMF_LIB_INSTALL=<path for library>  
      ESMF_MOD_INSTALL=<path for *.mod files> install
```

Some users may wish for the library to be built in a directory different from where the source code resides. To do this, build using:

```
gmake ESMF_BUILD=<path>
```

The `ESMF_BUILD` variable gives an alternate path in which to place the libraries, `*.mod` files and object files. This variable defaults to `ESMF_DIR`. If it is assigned another value, the `ESMF_BUILD` variable will need to be passed as an additional argument to the the above make commands. (Alternatively the variable `ESMF_BUILD` can be set in the environment (using `setenv` or `export`) and then it need not be passed to any make calls).

11.3 Running ESMF Self-Tests

Robustness and portability are primary goals of the ESMF development effort. To ensure that these goals are met, the ESMF includes a comprehensive suite of tests. They allow testing and validation of everything from individual functions to complete system tests. These test suites are used by the ESMF development team as part of their regular development process. ESMF users can run the testing suites to verify that the framework software was built and installed properly, and is running correctly on a particular platform.

Test targets will compile the ESMF library if it has not already been built.

11.3.1 Running ESMF Unit Tests

The unit tests provided with the ESMF library evaluate the following:

- correctness of individual functions
- behavior of individual modules or classes
- appropriate error handling

Unit tests can be run in either an exhaustive or a non-exhaustive (sanity check) mode. The exhaustive mode includes the sanity check tests. Typically, sanity checks for each ESMF capability include creating and destroying an object and testing its basic function using a valid argument set. In the exhaustive mode, a wide range of valid and non-valid arguments are evaluated for correct behavior.

The following commands are used to build and run the unit tests provided with the ESMF:

```
gmake [ ESMF_EXHAUSTIVE=<ON,OFF> ] tests
gmake [ ESMF_EXHAUSTIVE=<ON,OFF> ] tests_uni
```

The `tests_uni` target runs the tests on a single processor. The `tests` target runs the test on multiple processors.

The non-exhaustive set of unit tests should all pass. At this point in development, the exhaustive tests do not all pass. Current problems with unit tests are being tracked and corrected by the ESMF development team.

The results of running the unit tests can be found in the following location:

```
${ESMF_DIR}/test/test${ESMF_BOPT}/${ESMF_ARCH}.${ESMF_COMPILER}.${ESMF_PREC}.${ESMF_SITE}
```

For example, if your esmf source files have been placed in:

```
/usr/local/esmf
```

If your platform is a Linux uni-processor that has an installed Lahey Fortran compiler and `ESMF_COMPILER` has been set to `lahey`, then the build system configuration file will be:

```
build_config/Linux.lahey.default/build_rules.mk
```

If you want to run a debug version of non-exhaustive unit tests, then you use these commands from `/usr/local/esmf`:

```
setenv ESMF_DIR /usr/local/esmf
gmake ESMF_BOPT=g ESMF_SITE=lahey ESMF_EXHAUSTIVE=OFF tests_uni
```

If you are using ksh, then replace the setenv command with:

```
export ESMF_DIR=/usr/local/esmf
```

The results of the unit tests will be in:

```
/usr/local/esmf/test/testg/Linux.lahey.32.default/
```

At the end of unit test execution a script runs to analyze the results.

The script output indicates whether there are any unit test failures. The following is a sample from the script output:

There are a total of 1224 exhaustive multi processor unit tests, 1220 pass and 4 fail.

The unit tests in the following files all pass:

```
src/Infrastructure/Array/tests/ESMF_ArrayUTest.F90
src/Infrastructure/ArrayDataMap/tests/ESMF_ArrayDataMapUTest.F90
src/Infrastructure/Base/tests/ESMF_BaseUTest.F90
src/Infrastructure/Bundle/tests/ESMF_BundleUTest.F90
src/Infrastructure/BundleDataMap/tests/ESMF_BundleDataMapUTest.F90
src/Infrastructure/Config/tests/ESMF_ConfigUTest.F90
src/Infrastructure/DELayout/tests/ESMF_DELayoutUTest.F90
src/Infrastructure/Field/tests/ESMF_FRoute4UTest.F90
src/Infrastructure/Field/tests/ESMF_FieldUTest.F90
src/Infrastructure/FieldComm/tests/ESMF_FieldGatherUTest.F90
src/Infrastructure/FieldDataMap/tests/ESMF_FieldDataMapUTest.F90
src/Infrastructure/Grid/tests/ESMF_GridUTest.F90
src/Infrastructure/IOSpec/tests/ESMF_IOSpecUTest.F90
src/Infrastructure/LocalArray/tests/ESMF_ArrayDataUTest.F90
src/Infrastructure/LocalArray/tests/ESMF_ArrayF90PtrUTest.F90
src/Infrastructure/LocalArray/tests/ESMF_LocalArrayUTest.F90
src/Infrastructure/LogErr/tests/ESMF_LogErrUTest.F90
src/Infrastructure/Regrid/tests/ESMF_Regrid1UTest.F90
src/Infrastructure/Regrid/tests/ESMF_RegridUTest.F90
src/Infrastructure/TimeMgr/tests/ESMF_AlarmUTest.F90
src/Infrastructure/TimeMgr/tests/ESMF_CalRangeUTest.F90
src/Infrastructure/TimeMgr/tests/ESMF_ClockUTest.F90
src/Infrastructure/TimeMgr/tests/ESMF_TimeIntervalUTest.F90
src/Infrastructure/TimeMgr/tests/ESMF_TimeUTest.F90
src/Infrastructure/VM/tests/ESMF_VMBarrierUTest.F90
src/Infrastructure/VM/tests/ESMF_VMBroadcastUTest.F90
src/Infrastructure/VM/tests/ESMF_VMGatherUTest.F90
src/Infrastructure/VM/tests/ESMF_VMScatterUTest.F90
src/Infrastructure/VM/tests/ESMF_VMSendVMRecvUTest.F90
src/Infrastructure/VM/tests/ESMF_VMUTest.F90
src/Superstructure/Component/tests/ESMF_CplCompCreateUTest.F90
src/Superstructure/Component/tests/ESMF_GridCompCreateUTest.F90
src/Superstructure/State/tests/ESMF_StateUTest.F90
```

The following unit test files failed to build, failed to execute or crashed during execution:

```
src/Infrastructure/TimeMgr/tests/ESMF_CalendarUTest.F90
```

```
src/Infrastructure/VM/tests/ESMF_VMSendRecvUTest.F90
```

The following unit test files had failed unit tests:

```
src/Infrastructure/Field/tests/ESMF_FRoute8UTest.F90
src/Infrastructure/Grid/tests/ESMF_GridCreateUTest.F90
```

The following individual unit tests fail:

```
FAIL  DELayout Get Test, ESMF_FRoute8UTest.F90, line 139
FAIL  Grid Distribute Test, ESMF_GridCreateUTest.F90, line 198
```

The stdout files for the unit tests can be found at:

```
/home/bluedawn/svasquez/script_dirs/daily_builds/esmf/test/testO/AIX.default.64.default
```

The following is an example of the output generated when a unit test fails:

```
ESMF_FieldUTest.stdout: FAIL Unique default Field names Test, FLD1.5.1 & 1.7.1,
                        ESMF_FieldUTest.F90, line 204 Field names not unique
```

11.3.2 Running ESMF System Tests

The system tests provided with the ESMF library evaluate:

- interface agreement between parts of the system
- behavior of the system as a whole

The current system test suite includes tests that perform layout reduction operations, redistribution-transpose, halo operations, component creation and intra-grid communication. Some of the system tests are no longer compatible with the current API, but are included in the release for completeness. A complete description of each available system test and its current compatibility status can be found at the ESMF website, <http://www.esmf.ucar.edu>. The testing and validation page is accessible from the **Development** link on the navigation bar.

The following commands are used to build and run the system tests:

```
gmake [SYSTEM_TEST=xxx] system_tests
gmake [SYSTEM_TEST=xxx] system_tests_uni
```

The `system_tests_uni` target runs the tests on a single processor. The `system_tests` target runs the test on multiple processors.

If a particular `SYSTEM_TEST` is not specified, then all available system tests are built and run.

The results of the test can be found in the following location:

```
${ESMF_DIR}/test/test${ESMF_BOPT}/${ESMF_ARCH}.${ESMF_COMPILER}.${ESMF_PREC}.${ESMF_SITE}
```

For example, if your ESMF source files have been placed in your home directory:

~/esmf

and your platform and compiler configuration is:

Alpha multi-processor using the native compiler

and you want to run an optimized version of system test SimpleCoupling, then you use these commands from the directory ~/esmf.

```
setenv ESMF_PROJECT <project_name>
gmake ESMF_DIR='pwd' SYSTEM_TEST=ESMF_SimpleCoupling system_tests
```

If you are using ksh then replace the setenv command with this:

```
export ESMF_PROJECT=<project_name>
```

The results will be in:

~/esmf/test/test0/OSF1.default.64.default/ESMF_SimpleCouplingSTest.stdout

At the end of system test execution a script runs to analyze the results.

The script output indicates whether there are any system test failures. The following is a sample from the script output:

There are 14 system tests, 12 passed and 2 failed.

The following system tests passed:

```
src/system_tests/ESMF_CompCreate/ESMF_CompCreateSTest.F90
src/system_tests/ESMF_FieldExcl/ESMF_FieldExclSTest.F90
src/system_tests/ESMF_FieldHalo/ESMF_FieldHaloSTest.F90
src/system_tests/ESMF_FieldHaloPer/ESMF_FieldHaloPerSTest.F90
src/system_tests/ESMF_FieldRedist/ESMF_FieldRedistSTest.F90
src/system_tests/ESMF_FieldRegrid/ESMF_FieldRegridSTest.F90
src/system_tests/ESMF_FieldRegridMulti/ESMF_FieldRegridMultiSTest.F90
src/system_tests/ESMF_FieldRegridOrder/ESMF_FieldRegridOrderSTest.F90
src/system_tests/ESMF_FlowComp/ESMF_FlowCompSTest.F90
src/system_tests/ESMF_FlowWithCoupling/ESMF_FlowWithCouplingSTest.F90
src/system_tests/ESMF_SimpleCoupling/ESMF_SimpleCouplingSTest.F90
src/system_tests/ESMF_VectorStorage/ESMF_VectorStorageSTest.F90
```

The following system tests failed, did not build, or did not execute:

```
src/system_tests/ESMF_FieldRegridConserv/ESMF_FieldRegridConsrvSTest.F90
src/system_tests/ESMF_RowReduce/ESMF_RowReduceSTest.F90
```

The stdout files for the system_tests can be found at:

/home/bluedawn/svasquez/script_dirs/daily_builds/esmf/test/test0/AIX.default.64.default

11.4 Running ESMF Examples

11.4.1 Example Source Code

Example source code for each class is found in the class's example directory. For example, source code for the Time Manager class examples are found in this directory:

```
ESMF_DIR/src/Infrastructure/TimeMgr/examples/
```

While the example code is formatted to be included in the documentation, it also runs and compiles to ensure accuracy. Examples generally contain simple usage of the basic methods for the class.

11.4.2 Building and Running Examples

The GNU makefile targets `examples` and `examples_uni` build and run programs found in a class's examples directory. After the examples are built, the `examples` target runs the examples using multiple processors, while `examples_uni` runs the examples on a single processor.

These targets first build the ESMF library.

Run from `ESMF_DIR`, this command will build and run all examples on multiple processors:

```
gmake examples
```

If the command is run in an example source code directory, then only the example from that directory will be built and run. The examples and output files are created in this directory:

```
ESMF_DIR/examples/examples$ESMF_BOPT/$ESMF_ARCH.$ESMF_COMPILER.$ESMF_PREC.$ESMF_SIT
```

The name of an output file will begin with the name of the example that created it followed by `.stdout`.

At the end of examples execution a script runs to analyze the results.

The script output indicates whether there are any examples failures. The following is a sample from the script output:

There are 34 examples, 32 passed and 2 failed.

The following examples passed:

```
src/Infrastructure/Array/examples/ESMF_ArrayCreateEx.F90
src/Infrastructure/Array/examples/ESMF_ArrayGetEx.F90
src/Infrastructure/ArrayComm/examples/ESMF_ArrayCommEx.F90
src/Infrastructure/ArrayDataMap/examples/ESMF_ArrayDataMapEx.F90
src/Infrastructure/ArraySpec/examples/ESMF_ArraySpecEx.F90
src/Infrastructure/Bundle/examples/ESMF_BundleCreateEx.F90
src/Infrastructure/BundleDataMap/examples/ESMF_BundleDataMapEx.F90
src/Infrastructure/DELayout/examples/ESMF_DELayoutEx.F90
src/Infrastructure/Field/examples/ESMF_FieldCreateEx.F90
```

```

src/Infrastructure/Field/examples/ESMF_FieldFromUserEx.F90
src/Infrastructure/Field/examples/ESMF_FieldGlobalEx.F90
src/Infrastructure/Field/examples/ESMF_FieldWriteEx.F90
src/Infrastructure/FieldComm/examples/ESMF_FieldCommEx.F90
src/Infrastructure/FieldDataMap/examples/ESMF_FieldDataMapEx.F90
src/Infrastructure/LogErr/examples/ESMF_LogErrEx.F90
src/Infrastructure/Regrid/examples/ESMF_RegridEx.F90
src/Infrastructure/Route/examples/ESMF_RouteEx.F90
src/Infrastructure/TimeMgr/examples/ESMF_AlarmEx.F90
src/Infrastructure/TimeMgr/examples/ESMF_CalendarEx.F90
src/Infrastructure/TimeMgr/examples/ESMF_ClockEx.F90
src/Infrastructure/TimeMgr/examples/ESMF_TimeEx.F90
src/Infrastructure/VM/examples/ESMF_VMAllFullReduceEx.F90
src/Infrastructure/VM/examples/ESMF_VMComponentEx.F90
src/Infrastructure/VM/examples/ESMF_VMDefaultBasicsEx.F90
src/Infrastructure/VM/examples/ESMF_VMGetMPICommunicatorEx.F90
src/Infrastructure/VM/examples/ESMF_VMScatterVMGatherEx.F90
src/Infrastructure/VM/examples/ESMF_VMSendVMRecvEx.F90
src/Superstructure/Component/examples/ESMF_AppMainEx.F90
src/Superstructure/Component/examples/ESMF_CplEx.F90
src/Superstructure/Component/examples/ESMF_GCompEx.F90
src/Superstructure/State/examples/ESMF_StateEx.F90
src/Superstructure/State/examples/ESMF_StateReconcileEx.F90

```

The following examples failed, did not build, or did not execute:

```

src/Infrastructure/Grid/examples/ESMF_GridCreateEx.F90
src/Infrastructure/TimeMgr/examples/ESMF_TimeIntervalEx.F90

```

The stdout files for the examples can be found at:

/home/bluedawn/svasquez/script_dirs/daily_builds/esmf/examples/examplesO/AIX.default.64.de

12 How to Adapt Applications for ESMF

In this section we describe how to bring existing applications into the framework.

12.1 Individual Components

- Decide what parts will become Gridded Components

A Gridded Component is a self-contained piece of code which will be initialized, will be called once or many times to run, and then will be finalized. It will be expected to either take in data from other components/models, produce data, or both.

Generally a computational model like an ocean or atmosphere model will map either to a single component or to a set of multiple nested components.

- Decide what data is produced

A component provides data to other components using an ESMF State object. A component should fill the State object with a description of all possible values that it can export. Generally, a piece of code external to the component (the AppDriver, or a parent component) will be responsible for marking which of these items are actually going to be needed. Then the component can choose to either produce all possible data items (simpler but less efficient) or only produce the data items marked as being needed. The component should consult the CF data naming conventions when it is listing what data it can produce.

- Decide what data is needed

A component gets data from other components using an ESMF State object. The application developer must figure out how to get any required fields from other components in the application.

- Make the data blocks private

A component should communicate to other components only through the framework. All global data items should be private to Fortran modules, and ideally would be isolated to a single derived type which is allocated at run time.

- Divide the code up into start/middle/end phases

A component needs to provide 3 routines which handle initialization, running, and finalization. (For codes which have multiple phases of initialize, run, and finalize it is possible to have multiple initialize, run, and finalize routines.)

The initialize routine needs to allocate space, initialize data items, boundary conditions, and do whatever else is necessary in order to prepare the component to run.

For a sequential application in which all components are on the same set of processors, the run phase will be called multiple times. Each time the model is expected to take in any new data from other models, do its computation, and produce data needed by other components. A concurrent model, in which different components are run on different processors, may execute the same way. Alternatively, it may have its run routine called only once and may use different parts of the framework to arrange data exchange with other models. This feature is not yet implemented in ESMF.

The finalize routine needs to release space, write out results, close open files, and generally close down the computation gracefully.

- Make a "Set Services" subroutine

Components need to provide only a single externally visible entry point. It will be called at start time, and its job is to register with the framework which routines satisfy the initialize, run, and finalize requirements. It can also register the address of its private data block.

- Create ESMF Fields and Bundles for holding data

An ESMF State object is fundamentally an annotated list of other ESMF items, most often expected to be ESMF Bundles (groups of Fields on the same grid). Other things which can be placed in a State object are Fields, Arrays (raw data with no gridding/coordinate information) and other States (generally used by coupling code). Any data which is going to be received from other components or sent to other components needs to be represented as an ESMF object.

To create an ESMF Field the code must create an ESMF Array object to contain the data values, and usually an ESMF Grid object to describe the computational grid where the values are located. If this is an observational data stream the locations of the data values will be held in an ESMF Location Stream object instead of a Grid. (Location Streams are not yet fully implemented.)

- Be able to read an ESMF clock

During the execution of the run routine, information about time is transferred between components through ESMF Clocks. The component needs to be able to at least query a Clock for the current time using framework methods.

- Decide how much of the lower level infrastructure to use

The ESMF framework provides a rich set of time management functions, data management and query functions, IO functions, and other utility routines which help to insulate the user's code from the vast differences in hardware architectures, system software, and runtime environments. It is up to the user to select which parts of these functions they choose to use.

12.2 Full Application

- Decide on which components to use

Select from the set of ESMF components available.

- Understand the data flow in order to customize a Coupler Component

Examine what data is produced by each component and what data is needed by each component. The role of Coupler Components in the ESMF is to set up any necessary regridding and data conversions to match output data from one component to input data in another.

- Write or adapt a Coupler Component

Decide on a strategy for how to do the coupling. There can be a single coupler for the application or multiple couplers. Single couplers follow a "hub and spoke" model. Multiple couplers can couple between subsets of the components, and can be written to couple either only one-way (e.g. output of component A into input of component B), or two-way (both A to B and B to A).

The coupler must understand States, Fields, Bundles, Grids, and Arrays and ESMF execution/environment objects such as DELayouts.

- Use or adapt a main program

The main program can be an unchanged copy of the file found in the `AppDriver` directory. The only customization needed is to set the name of the top level Gridded Component, and to set the name of the `SetServices` routine. The template file includes a call to `ESMF_Initialize()` which ensures the framework initialization code is run, and will provide the environment for components to be created and run.

Although ESMF provides source code for the main program, it is **not** considered part of the framework and can be changed by the user as needed.

The final thing the main program must do is call `ESMF_Finalize()`. This will close down the framework and release any associated resources.

The main program is responsible for creating a top-level Gridded Component, which in turn creates other Gridded and Coupler Components. We encourage this hierarchical design because it aids in extensibility. The top-level component contains the main time loop and is responsible for calling the `SetServices` entry point for each child component it creates.

13 Glossary

This glossary defines terms used in Earth system modeling to describe parallel computer architectures, grids and grid decompositions, and numerical and computational methods.

360-day calendar A calendar in which every one of twelve months has thirty days. See also Calendar, no-leap calendar.

Accumulator A facility for collecting and averaging data values. Generally accumulators are associated with temporal averaging, although they might be associated with other weighted averaging operations. ESMF does not yet have accumulators.

Address space (ASP) A term that refers to the memory that a computer program can write to directly using simple language primitives.

Alarm The ESMF Alarm class represents an event that occurs at a particular time (or set of times). It is like an alarm on a real alarm clock except that in order to determine whether it is "ringing", an ESMF Alarm is "read" by an explicit application action. An Alarm is associated with a particular Clock.

Application A coherent computational entity run as a single executable or set of communicating executables. It typically consists of a set of interacting components. See also component.

Array An ESMF class that represents a multi-dimensional data array. Unlike a native Fortran or C++ array, an ESMF Array can store information about its halo. See also halo.

Background grid A background grid associates each point in an observational data stream (Location Stream) with a location on a grid. A single grid cell may contain zero or more Location Stream points. See also Location Stream, cell.

Bundle The ESMF Bundle class represents a set of fields that are associated with the same physical grid and are distributed in a similar fashion across the same physical axes. Fields within a Bundle may be staggered differently and may have different dimensions. See also Field.

Calendar Calendar is an ESMF class that stores a representation of a particular calendar type, such as Gregorian. In this glossary we list calendars specific to modeling, such as 360-day and no-leap.

Cell A physical location that is specified by both its extent (vertices) and nominal central location, and is associated with a single integer index value or a set of integer index values (e.g. (i) for 1-d, (i,j) for 2-d, (i,j,k) for 3d). See also index.

Clock Clock is an ESMF class that tracks the passage of time and reports the current time instant, like a real clock. An ESMF Clock is stepped forward in increments of a time step, and can be associated with one or more Alarms. See also Time, Time Interval, Alarm.

Component A large-scale computational entity associated with a particular physical process or computational function, such as a land model. A component is also an ESMF class that represents a large-scale computational entity; currently ESMF supports Gridded Component and Coupler Component classes. Components may be generic or user-supplied.

Computational domain For a given DE, the data points that have unique global indices and are updated by the DE. See also exclusive domain, total domain, halo.

Compute resource Something that appears as a physical or virtual computer resource. Example of compute resources are a CPU, a network connection, a communication API, a protocol, a particular network fabric or a piece of computer memory.

Concurrent execution Concurrent execution of model components occurs when two or more components, whether in the same or different executables, run simultaneously. Components executing concurrently may have coincident or non-overlapping distributions. See also sequential execution.

Coupler Component An ESMF component that includes all data and actions needed to enable communication between two or more Gridded Components. See also component, Gridded Component.

Data dependency The property of a computational operator that defines the data indices required to perform the computation at a point.

Data parallel The quality of an application that allows roughly the same calculation to be performed by all processors at the same time on the same data set, which is partitioned among multiple memory locations. Single components that do not contain nested components are often data parallel. See also task parallel, SPMD, MPMD.

Data transpose Rearrangement of data arrays that share the same global domain.

Day of year The day number in the calendar year. January 1 is day 1 of the year. Day of year expressed in a floating point format is used to express the day number plus the time of day. For example, assuming a Gregorian calendar:

<u>date</u>	<u>day of year</u>
10 January 2000, 6Z	10.25
31 December 2000, 18Z	366.75

DE Short for Decomposition Element.

DELayout DELayout is the ESMF class that defines the topology of a set of DEs and specifies how the DEs are assigned to PETs in an ESMF Virtual Machine.

Decomposition Element (DE) Decomposition Elements represent a virtual portion of a computational task. A DELayout assigns a topology to Decomposition Elements. See also DELayout.

Deep object In an environment in which the calling and implementation language of a library are different, deep objects are defined as those whose memory is allocated by the implementation language. See also shallow object.

Distributed Grid Distributed Grid is a private ESMF class that defines the decomposition of a Grid's global index space across a DELayout. Distributed Grid objects are contained in an ESMF Grid. See also Grid, Physical Grid, DELayout.

Distribution The function that expresses the relationship between the indices in a Distributed Grid and the elements in a DELayout. See also Distributed Grid, DELayout.

Domain decomposition The act of grid distribution: creating a DELayout; and associating grid points with the DELayout. The dimensionality of the domain decomposition is the same as the dimensionality of the associated DELayout.

Exact The word exact is used to denote entities, such as time instants and time intervals, for which truncation-free arithmetic is required.

Exchange grid A grid whose vertices are formed by the intersection of the vertices of two overlying grids. Each cell in the exchange grid overlies exactly one cell in each grid of the exchange. See also grid, cell.

Exchange Packets Exchange Packets are a private ESMF class that contains data in an optimal form for data transfers.

Exclusive domain For a given DE, the set of data points that are not replicated on any other DE. See also total domain, computational domain, halo.

Executable A program that is under independent control by the operating system.

Export State The data and metadata that a component can make available for exchange with other components. This may be data at a physical boundary (e.g land-atmosphere interface) or in other cases, it might be the entire model state. See also State, import State.

Field The ESMF Field class represents a physical quantity defined within a region of space. A Field includes a Grid and any metadata necessary for a full description of its data. See also Grid.

Framework We use the term framework to refer to a structured collection of software building blocks that can be used and customized to develop components, assemble them into an application, and run the application.

Generic component A generic component is one supplied by the framework. The user is not expected to customize or otherwise modify it. ESMF does not currently contain any generic components. See also user component, component.

Generic transform A generic transform is an operation supplied by the framework, for example, a method that converts gridded data from one supported Physical Grid and/or decomposition to another using a specified technique. See also user transform.

Global domain A global domain refers to the full extent of a DELayout or Grid.

Global reduction Reduction operations (sum, max, min, etc.) that condense data distributed over a global domain. See also global broadcast.

Global broadcast Scatter operations on data distributed over a global domain. See also global reduction.

Grid The discrete division of space associated with a particular coordinate system. The ESMF Grid class contains all Physical Grid and memory organization information (via Distributed Grid and DELayout) required to manipulate Fields, as well as to create and execute Grid transforms. See also Physical Grid, Distributed Grid, DELayout.

Grid metrics Terms relating measurements in index space to Physical Grid quantities like distances and areas.

Grid staggering A descriptor of relative locations of scalar and vector data on a structured grid. On different staggered grids, vector data may lie at cell faces or vertices, while scalar data may lie in the interior.

Grid topology Description of data connectivities for a grid.

Grid union The formation of a new grid by taking the union of the vertices of two input grids. See also Grid.

Gridded Component An ESMF class that represents a component that is associated with one or more grids. No requirements may be placed on the physical content of a Gridded Component's data or on the nature of its computations. See also component, Coupler Component.

Halo For a given DE, a halo is a set of data points from the computational domains of neighboring DEs that are replicated locally for computational convenience. A halo can be defined as all the data points in a DE's total domain excluding those in its computational domain. See also computational domain, total domain, exclusive domain.

Halo update A halo update operation involves synchronization of the values of some or all halo points with the current values of those points on other DEs. See also halo.

Import State The data and metadata that a component requires from other components in order to run. See also State, export State.

Index An integer value associated with a set of coordinates.

Index space The space implied by a set of indices. An index space has a defined dimensionality and connectivity.

Index space location A location within an index space. A index space location may be fractional. See also physical location.

Instantiate To create an actual instance of a software class. For example, each variable of derived type Field in an ESMF Fortran application is an instance of the Field class.

Interface Used generally to refer to a set of operations that characterize the behavior of a class or a component. Also used to refer to the name and argument list of a particular method.

JMC Joint Milestone Codeset. This is the set of climate, weather and data assimilation applications that will be used as ESMF testbeds during the initial NASA-funded phase of ESMF development.

Location Stream An ESMF class that represents a list of locations with no assumed relationship between these locations. The elements of a Location Stream are not assumed to share the same metadata. Location Streams are not yet implemented. See also background grid.

Logically rectangular grid A grid in which sequential indices are physically adjacent, and in which the extent of each index is independent of the other indices. See also Grid.

Loose Bundle A loose Bundle is an ESMF Bundle object that contains fields whose data is not contiguous in memory. See also Bundle, packed Bundle.

Machine model A generic representation of the computing platform architecture.

Mask A data field marking a span within a larger data field.

Memory domain The portion of memory associated with the data on a given DE. The memory domain is always at least as large as the total domain. See also total domain.

MPMD Multiple Program Multiple Datastream. Multiple executables, any of which could itself be an SPMD executable, executing independently within an application. See also SPMD

Node A node is a set of computational resources that is typically located in close proximity on a computing platform and that is associated with a single shared memory buffer.

No-leap calendar In this calendar every year uses the same months and days per month as in a non-leap year of a Gregorian calendar. See also Calendar, 360-day calendar.

Packed Bundle A packed Bundle is an ESMF Bundle object that contains a data buffer with field data arranged contiguously in memory. See also Bundle, loose Bundle.

PE Short for Processing Element.

PET Short for Persistent Execution Thread.

Persistent Execution Thread (PET) Provides a path for executing an instruction sequence. A PET has a lifetime at least as long as the associated data objects. The PET is a key abstraction used in the ESMF Virtual Machine.

Physical Grid Physical Grid is a private ESMF class that contains a variety of information on the location in physical space and physical metrics (area, grid lengths, etc.) of various grid points. Physical Grid objects are contained in an ESMF Grid. See also Grid, Distributed Grid.

Physical location A point in physical space to which a data point pertains. See also index space location.

Platform The processor hardware, operating system, compiler and parallel library that together form a unique compilation target.

Processing Element (PE) A Processing Element (PE) is the smallest physical processing unit available on a particular hardware platform.

Scheduler An operating system component that assigns system resources (processors, memory, CPU time, I/O channels, etc.) to executables.

Sequential execution Sequential execution of model components describes the case in which one component waits for another to finish before it begins to run. Components executing sequentially may be in the same or different executables and may have coincident or non-overlapping memory distributions. See concurrent execution glos:ConcurrentExecution.

Shallow object In an environment in which the calling and implementation language of a library are different, shallow objects are defined as those whose memory is allocated by the calling language. See also deep object.

Span The physical extent associated with a grid.

SPMD Single Program Multiple Datastream. A single executable, possibly with many components (representing for example the atmosphere, the ocean, land surface) executing serially or concurrently. See also MPMD.

State The ESMF State class may contain Arrays, Bundles, Fields, or other States. It is used to transfer data between components. See also import State, export State.

System time Time spent doing system tasks such as I/O or in system calls. May also include time spent running other processes on a multiprocessor system. See also user time, wall clock time.

Task parallel The quality of an application that allows different calculations to be performed by different processors at the same time on what are usually different data sets. Large-scale task parallelism is often associated with multi-component applications in which each component represents a separate domain or function. Task parallel applications may be run with components executing either sequentially or concurrently, and either in a SPMD or MPMD mode. See also data parallel, SPMD, MPMD, sequential execution, concurrent execution.

Time Time is an ESMF class that is made up of a time and date and an associated calendar. It may include a time zone. *Jan 3rd 1999, 03:30:24.56s, UTC* is one example of a Time. See also Calendar.

Time Interval Time Interval is an ESMF class that represents the period between any two time instants, measured in units, such as days, seconds, and fractions of a second. The periods *2 days and 10 seconds, 86400 and 1/3 seconds* and *31104000.75 seconds* are all possible values for Time Intervals. Mathematical operations such as addition, multiplication, and subdivision can be applied to Time Intervals, and they can have negative values. See also Time

Total domain For a given DE, the entirety of the data points allocated, included replicated points from neighboring DEs. See also computational domain, exclusive domain, halo

User component A component that is customized or written by the user. All ESMF components are currently user components. See also generic component.

User time Processor time actually spent executing a PET's code. See also system time, wall clock time.

User transform A user-supplied method that is used to extend framework capabilities beyond generic transforms. See also generic transform.

VM Short for Virtual Machine.

Virtual Machine (VM) An ESMF class that abstracts hardware and operating system details. The VM's responsibilities are resource management and topological description of the underlying compute resources in terms of PETs. In addition the VM provides a transparent, low level communication API.

Wall clock time Elapsed real-world time (i.e. difference between start time minus stop time). See also system time, user time.
