Earth System Modeling Framework

ESMF Reference Manual for Fortran

Version 6.3.0r

January 31, 2014

http://www.earthsystemmodeling.org
Acknowledgements

The ESMF software is based on the contributions of a broad community. Below are the software packages that are included in ESMF or strongly influenced our design. We’d like to express our gratitude to the developers of these codes for access to their software as well as their ideas and advice.

- Parallel I/O (PIO) developers at NCAR and DOE Laboratories for their excellent work on this package and their help in making it work with ESMF
- The Spherical Coordinate Remapping and Interpolation Package (SCRIP) from Los Alamos, which informed the design of our regridding functionality
- The Model Coupling Toolkit (MCT) from Argonne National Laboratory, on which we based our sparse matrix multiply approach to general regridding
- The Inpack configuration attributes package from NASA Goddard, which was adapted for use in ESMF by members of NASA Global Modeling and Assimilation group
- The Flexible Modeling System (FMS) package from GFDL and the Goddard Earth Modeling System (GEMS) from NASA Goddard, both of which provided inspiration for the overall ESMF architecture
- The Common Component Architecture (CCA) effort within the Department of Energy, from which we drew many ideas about how to design components
- The Vector Signal Image Processing Library (VSIPL) and its predecessors, which informed many aspects of our design, and the radar system software design group at Lincoln Laboratory
- The Portable, Extensible Toolkit for Scientific Computation (PETSc) package from Argonne National Laboratories, on which we based our initial makefile system
- The Community Climate System Model (CCSM) and Weather Research and Forecasting (WRF) modeling groups at NCAR, who have provided valuable feedback on the design and implementation of the framework

      25.3.3 Get Grid, Array, and other information from a Field ....................... 272
      25.3.4 Create a Field with a Grid, typekind, and rank .............................. 273
      25.3.5 Create a Field with a Grid and Arrayspec ....................................... 273
      25.3.6 Create a Field with a Grid and Array ............................................ 275
      25.3.7 Create an empty Field and complete it with FieldEmptySet and FieldEmptyComplete ........................................ 275
      25.3.8 Create an empty Field and complete it with FieldEmptyComplete .......... 276
      25.3.9 Create a 7D Field with a 5D Grid and 2D ungridded bounds from a Fortran data array ......................................................... 277
      25.3.10 Create a 2D Field with a 2D Grid and a Fortran data array .......... 278
      25.3.11 Create a 2D Field with a 2D Grid and a Fortran data pointer ......... 279
      25.3.12 Create a 3D Field with a 2D Grid and a 3D Fortran data array ....... 279
25.3.13 Create a 3D Field with a 2D Grid and a 3D Fortran data array with gridToFieldMap argument
25.3.14 Create a 3D Field with a 2D Grid and a 3D Fortran data array with halos
25.3.15 Create a Field from a LocStream, typekind, and rank
25.3.16 Create a Field from a LocStream and arrayspec
25.3.17 Create a Field from a Mesh, typekind, and rank
25.3.18 Create a Field from a Mesh and arrayspec
25.3.19 Create a Field from a Mesh and an Array
25.3.20 Create a Field from a Mesh and an ArraySpec with optional features
25.3.21 Create a Field with replicated dimensions
25.3.22 Create a Field on an arbitrarily distributed Grid with replicated dimensions & ungridded bounds
25.3.23 Create a Field on an arbitrarily distributed Grid
25.3.24 Field regridding
25.3.25 Field regrid with masking
25.3.26 Field regrid example: Mesh to Mesh
25.3.27 Gather Field data onto root PET
25.3.28 Scatter Field data from root PET onto its set of joint PETs
25.3.29 Redistribute data from source Field to destination Field
25.3.30 FieldRedist as a form of scatter involving arbitrary distribution
25.3.31 FieldRedist as a form of gather involving arbitrary distribution
25.3.32 Sparse matrix multiplication from source Field to destination Field
25.3.33 Field Halo solving a domain decomposed heat transfer problem
25.4 Restrictions and Future Work
25.5 Design and Implementation Notes

### 29 ArraySpec Class

| 29.1 | Description | 547 |
| 29.2 | Use and Examples | 547 |
| 29.2.1 | Set ArraySpec values | 548 |
| 29.2.2 | Get ArraySpec values | 548 |
| 29.3 | Restrictions and Future Work | 549 |
| 29.4 | Design and Implementation Notes | 549 |
| 29.5 | Class API | 549 |
| 29.5.1 | ESMF_ArraySpecAssignment(=) | 549 |
| 29.5.2 | ESMF_ArraySpecOperator(==) | 550 |
| 29.5.3 | ESMF_ArraySpecOperator(/=) | 550 |
| 29.5.4 | ESMF_ArraySpecGet | 551 |
| 29.5.5 | ESMF_ArraySpecPrint | 552 |
| 29.5.6 | ESMF_ArraySpecSet | 552 |
| 29.5.7 | ESMF_ArraySpecValidate | 553 |

### 30 Grid Class

| 30.1 | Description | 554 |
| 30.1.1 | Grid Representation in ESMF | 554 |
| 30.1.2 | Supported Grids | 555 |
| 30.1.3 | Grid Topologies and Periodicity | 555 |
| 30.1.4 | Grid Distribution | 556 |
| 30.1.5 | Grid Coordinates | 556 |
| 30.1.6 | Coordinate Specification and Generation | 557 |
| 30.1.7 | Staggering | 557 |
| 30.1.8 | Masking | 557 |
| 30.2 | Constants | 558 |
| 30.2.1 | ESMF_GRIDCONN | 558 |
| 30.2.2 | ESMFGRIDITEM | 559 |
| 30.2.3 | ESMFGRIDMATCH | 559 |
| 30.2.4 | ESMFGRIDSTATUS | 559 |
| 30.2.5 | ESMFPOLEKIND | 560 |
| 30.2.6 | ESMFSTAGGERLOC | 560 |
| 30.2.7 | ESMFFILEFORMAT | 562 |
| 30.3 | Use and Examples | 562 |
| 30.3.1 | Create single-tile Grid shortcut method | 562 |
| 30.3.2 | Create a 2D regularly distributed rectilinear Grid with uniformly spaced coordinates | 565 |
| 30.3.3 | Create a periodic 2D regularly distributed rectilinear Grid | 566 |
| 30.3.4 | Create a 2D irregularly distributed rectilinear Grid with uniformly spaced coordinates | 568 |
| 30.3.5 | Create a 2D irregularly distributed Grid with curvilinear coordinates | 569 |
| 30.3.6 | Create an irregularly distributed rectilinear Grid with a non-distributed vertical dimension | 571 |
32.1 Description

32.1.1 Mesh representation in ESMF

32.1.2 Supported Meshes

32.2 Constants

32.2.1 ESMF_MESHELEMENTTYPE

32.2.2 ESMF_FILEFORMAT

32.3 Use and Examples

32.3.1 Mesh creation

32.3.2 Create a small single PET Mesh in one step

32.3.3 Create a small single PET Mesh in three steps

32.3.4 Create a small Mesh on 4 PETs in one step

32.3.5 Create a copy of a Mesh with a new distribution

32.3.6 Create a Mesh from an unstructured grid file

32.3.7 Remove Mesh memory

32.3.8 Mesh Masking

32.4 Class API

32.4.1 ESMF_MeshAssignment(=)

32.4.2 ESMF_MeshOperator(==)

32.4.3 ESMF_MeshOperator(/=)

32.4.4 ESMF_MeshAddElements

32.4.5 ESMF_MeshAddNodes

32.4.6 ESMF_MeshCreate

32.4.7 ESMF_MeshCreate

32.4.8 ESMF_MeshCreate

32.4.9 ESMF_MeshCreate

32.4.10 ESMF_MeshDestroy

32.4.11 ESMF_MeshFreeMemory

32.4.12 ESMF_MeshGet

33 XGrid Class

33.1 Description

33.2 Constants

33.2.1 ESMF_XGRIDSIDE

33.3 Use and Examples

33.3.1 Create an XGrid from Grids then use it for regridding

33.3.2 Using XGrid in Earth System modeling

33.3.3 Create an XGrid from user input data then use it for regridding

33.3.4 Query the XGrid for its internal information

33.3.5 Destroying the XGrid and other resources

33.4 Restrictions and Future Work

33.5 Design and Implementation Notes

33.6 Class API

33.6.1 ESMF_XGridAssignment(=)

33.6.2 ESMF_XGridOperator(==)

33.6.3 ESMF_XGridOperator(/=)

33.6.4 ESMF_XGridCreate

33.6.5 ESMF_XGridCreateFromSparseMat

33.6.6 ESMF_XGridDestroy

33.6.7 ESMF_XGridGet

33.6.8 ESMF_XGridGet

Part I

ESMF Overview
1 What is the Earth System Modeling Framework?

The Earth System Modeling Framework (ESMF) is a suite of software tools for developing high-performance, multi-component Earth science modeling applications. Such applications may include a few or dozens of components representing atmospheric, oceanic, terrestrial, or other physical domains, and their constituent processes (dynamical, chemical, biological, etc.). Often these components are developed by different groups independently, and must be “coupled” together using software that transfers and transforms data among the components in order to form functional simulations.

ESMF supports the development of these complex applications in a number of ways. It introduces a set of simple, consistent component interfaces that apply to all types of components, including couplers themselves. These interfaces expose in an obvious way the inputs and outputs of each component. It offers a variety of data structures for transferring data between components, and libraries for regridding, time advancement, and other common modeling functions. Finally, it provides a growing set of tools for using metadata to describe components and their input and output fields. This capability is important because components that are self-describing can be integrated more easily into automated workflows, model and dataset distribution and analysis portals, and other emerging “semantically enabled” computational environments.

ESMF is not a single Earth system model into which all components must fit, and its distribution doesn’t contain any scientific code. Rather it provides a way of structuring components so that they can be used in many different user-written applications and contexts with minimal code modification, and so they can be coupled together in new configurations with relative ease. The idea is to create many components across a broad community, and so to encourage new collaborations and combinations.

ESMF offers the flexibility needed by this diverse user base. It is tested nightly on more than two dozen platform/compiler combinations; can be run on one processor or thousands; supports shared and distributed memory programming models and a hybrid model; can run components sequentially (on all the same processors) or concurrently (on mutually exclusive processors); and supports single executable or multiple executable modes.

ESMF’s generality and breadth of function can make it daunting for the novice user. To help users navigate the software, we try to apply consistent names and behavior throughout and to provide many examples. The large-scale structure of the software is straightforward. The utilities and data structures for building modeling components are called the ESMF infrastructure. The coupling interfaces and drivers are called the superstructure. User code sits between these two layers, making calls to the infrastructure libraries underneath and being scheduled and synchronized by the superstructure above. The configuration resembles a sandwich, as shown in Figure 1.

ESMF users may choose to extensively rewrite their codes to take advantage of the ESMF infrastructure, or they may decide to simply wrap their components in the ESMF superstructure in order to utilize framework coupling services. Either way, we encourage users to contact our support team if questions arise about how to best use the software, or how to structure their application. ESMF is more than software; it’s a group of people dedicated to realizing the vision of a collaborative model development community that spans institutional and national bounds.

2 The ESMF Reference Manual for Fortran

ESMF has a complete set of Fortran interfaces and some C interfaces. This ESMF Reference Manual is a listing of ESMF interfaces for Fortran.

Interfaces are grouped by class. A class is comprised of the data and methods for a specific concept like a physical field. Superstructure classes are listed first in this Manual, followed by infrastructure classes.

1 Since the customer base for it is small, we have not yet prepared a comprehensive reference manual for C.
Figure 1: Schematic of the ESMF “sandwich” architecture. The framework consists of two parts, an upper level **superstructure** layer and a lower level **infrastructure** layer. User code is sandwiched between these two layers.

The major classes in the ESMF superstructure are Components, which usually represent large pieces of functionality such as atmosphere and ocean models, and States, which are the data structures used to transfer data between Components. There are both data structures and utilities in the ESMF infrastructure. Data structures include multi-dimensional Arrays, Fields that are comprised of an Array and a Grid, and collections of Arrays and Fields called ArrayBundles and FieldBundles, respectively. There are utility libraries for data decomposition and communications, time management, logging and error handling, and application configuration.

3 How to Contact User Support and Find Additional Information

The ESMF team can answer questions about the interfaces presented in this document. For user support, please contact **esmf_support@list.woc.noaa.gov**.

The website, [http://www.earthsystemmodeling.org](http://www.earthsystemmodeling.org) provides more information of the ESMF project as a whole. The website includes release notes and known bugs for each version of the framework, supported platforms, project history, values, and metrics, related projects, the ESMF management structure, and more. The **ESMF User’s Guide** contains build and installation instructions, an overview of the ESMF system and a description of how its classes interrelate (this version of the document corresponds to the last public version of the framework). Also available on the ESMF website is the **ESMF Developer’s Guide** that details ESMF procedures and conventions.

4 How to Submit Comments, Bug Reports, and Feature Requests

We welcome input on any aspect of the ESMF project. Send questions and comments to **esmf_support@list.woc.noaa.gov**.
5 Conventions

5.1 Typeface and Diagram Conventions

The following conventions for fonts and capitalization are used in this and other ESMF documents.

<table>
<thead>
<tr>
<th>Style</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>italics</em></td>
<td>documents</td>
<td><em>ESMF Reference Manual</em></td>
</tr>
<tr>
<td><strong>courier</strong></td>
<td>code fragments</td>

<td>An <em>address space</em> is ...</td>
</tr>
<tr>
<td>boldface</td>
<td>web links and tabs</td>
<td>Developers tab on the website</td>
</tr>
<tr>
<td>Capitals</td>
<td>ESMF class name</td>
<td>DataMap</td>
</tr>
</tbody>
</table>

ESMF class names frequently coincide with words commonly used within the Earth system domain (field, grid, component, array, etc.) The convention we adopt in this manual is that if a word is used in the context of an ESMF class name it is capitalized, and if the word is used in a more general context it remains in lower case. We would write, for example, that an ESMF Field class represents a physical field.

Diagrams are drawn using the Unified Modeling Language (UML). UML is a visual tool that can illustrate the structure of classes, define relationships between classes, and describe sequences of actions. A reader interested in more detail can refer to a text such as *The Unified Modeling Language Reference Manual.*

5.2 Method Name and Argument Conventions

Method names begin with `ESMF_`, followed by the class name, followed by the name of the operation being performed. Each new word is capitalized. Although Fortran interfaces are not case-sensitive, we use case to help parse multi-word names.

For method arguments that are multi-word, the first word is lower case and subsequent words begin with upper case. ESMF class names (including typed flags) are an exception. When multi-word class names appear in argument lists, all letters after the first are lower case. The first letter is lower case if the class is the first word in the argument and upper case otherwise. For example, in an argument list the DELayout class name may appear as `delayout` or `srcDelayout`.

Most Fortran calls in the ESMF are subroutines, with any returned values passed through the interface. For the sake of convenience, some ESMF calls are written as functions.

A typical ESMF call looks like this:

```fortran
call ESMF_<ClassName><Operation>(classname, firstArgument, secondArgument, ..., rc)
```

where

- `<ClassName>` is the class name,
- `<Operation>` is the name of the action to be performed,
- `classname` is a variable of the derived type associated with the class,
- the `arg` arguments are whatever other variables are required for the operation,
- and `rc` is a return code.
6 The ESMF Application Programming Interface

The ESMF Application Programming Interface (API) is based on the object-oriented programming concept of a class. A class is a software construct that is used for grouping a set of related variables together with the subroutines and functions that operate on them. We use classes in ESMF because they help to organize the code, and often make it easier to maintain and understand. A particular instance of a class is called an object. For example, Field is an ESMF class. An actual Field called temperature is an object. That is about as far as we will go into software engineering terminology.

The Fortran interface is implemented so that the variables associated with a class are stored in a derived type. For example, an ESMF_Field derived type stores the data array, grid information, and metadata associated with a physical field. The derived type for each class is stored in a Fortran module, and the operations associated with each class are defined as module procedures. We use the Fortran features of generic functions and optional arguments extensively to simplify our interfaces.

The modules for ESMF are bundled together and can be accessed with a single USE statement, USE ESMF.

6.1 Standard Methods and Interface Rules

ESMF defines a set of standard methods and interface rules that hold across the entire API. These are:

- ESMF_<Class>Create() and ESMF_<Class>Destroy(), for creating and destroying objects of ESMF classes that require internal memory management (called ESMF deep classes). The ESMF_<Class>Create() method allocates memory for the object itself and for internal variables, and initializes variables where appropriate. It is always written as a Fortran function that returns a derived type instance of the class, i.e. an object.

- ESMF_<Class>Set() and ESMF_<Class>Get(), for setting and retrieving a particular item or flag. In general, these methods are overloaded for all cases where the item can be manipulated as a name/value pair. If identifying the item requires more than a name, or if the class is of sufficient complexity that overloading in this way would result in an overwhelming number of options, we define specific ESMF_<Class>Set<Something>() and ESMF_<Class>Get<Something>() interfaces.

- ESMF_<Class>Add(), ESMF_<Class>AddReplace(), ESMF_<Class>Remove(), and ESMF_<Class>Replace(), for manipulating objects of ESMF container classes - such as ESMF_State and ESMF_FieldBundle. For example, the ESMF_FieldBundleAdd() method adds another Field to an existing FieldBundle object.

- ESMF_<Class>Print(), for printing the contents of an object to standard out. This method is mainly intended for debugging.

- ESMF_<Class>ReadRestart() and ESMF_<Class>WriteRestart(), for saving the contents of a class and restoring it exactly. Read and write restart methods have not yet been implemented for most ESMF classes, so where necessary the user needs to write restart values themselves.

- ESMF_<Class>Validate(), for determining whether a class is internally consistent. For example, ESMF_FieldValidate() validates the internal consistency of a Field object.

6.2 Deep and Shallow Classes

The ESMF contains two types of classes.
**Deep** classes require ESMF_<Class>Create() and ESMF_<Class>Destroy() calls. They involve memory allocation take significant time to set up (involving memory management) and should not be created in a time-critical portion of code. Deep objects persist even after the method in which they were created has returned. Most classes in ESMF, including GridComp, CplComp, State, Fields, FieldBundles, Arrays, ArrayBundles, Grids, and Clocks, fall into this category.

**Shallow** classes do not possess ESMF_<Class>Create() and ESMF_<Class>Destroy() calls. They are simply declared and their values set using an ESMF_<Class>Set() call. Examples of shallow classes are Time, TimeInterval, and ArraySpec. Shallow classes do not take long to set up and can be declared and set within a time-critical code segment. Shallow objects stop existing when the method in which they were declared has returned.

An exception to this is when a shallow object, such as a Time, is stored in a deep object such as a Clock. The Clock then carries a copy of the Time in persistent memory. The Time is deallocated with the ESMF_ClockDestroy() call.

See Section 9, Overall Design and Implementation Notes, for a brief discussion of deep and shallow classes from an implementation perspective. For an in-depth look at the design and inter-language issues related to deep and shallow classes, see the ESMF Implementation Report.

### 6.3 Special Methods

The following are special methods which, in one case, are required by any application using ESMF, and in the other case must be called by any application that is using ESMF Components.

- ESMF_Initialize() and ESMF_Finalize() are required methods that must bracket the use of ESMF within an application. They manage the resources required to run ESMF and shut it down gracefully. ESMF does not support restarts in the same executable, i.e. ESMF_Initialize() should not be called after ESMF_Finalize().

- ESMF_<Type>CompInitialize(), ESMF_<Type>CompRun(), and ESMF_<Type>CompFinalize() are component methods that are used at the highest level within ESMF. <Type> may be <Grid>, for Gridded Components such as oceans or atmospheres, or <Cpl>, for Coupler Components that are used to connect them. The content of these methods is not part of the ESMF. Instead the methods call into associated subroutines within user code.

### 6.4 The ESMF Data Hierarchy

The ESMF API is organized around an hierarchy of classes that contain model data. The operations that are performed on model data, such as regridding, redistribution, and halo updates, are methods of these classes.

The main data classes in ESMF, in order of increasing complexity, are:

- **Array** An ESMF Array is a distributed, multi-dimensional array that can carry information such as its type, kind, rank, and associated halo widths. It contains a reference to a native Fortran array.

- **ArrayBundle** An ArrayBundle is a collection of Arrays, not necessarily distributed in the same manner. It is useful for performing collective data operations and communications.

- **Field** A Field represents a physical scalar or vector field. It contains a reference to an Array along with grid information and metadata.
• **FieldBundle** A FieldBundle is a collection of Fields discretized on the same grid. The staggering of data points may be different for different Fields within a FieldBundle. Like the ArrayBundle, it is useful for performing collective data operations and communications.

• **State** A State represents the collection of data that a Component either requires to run (an Import State) or can make available to other Components (an Export State). States may contain references to Arrays, ArrayBundles, Fields, FieldBundles, or other States.

• **Component** A Component is a piece of software with a distinct function. ESMF currently recognizes two types of Components. Components that represent a physical domain or process, such as an atmospheric model, are called Gridded Components since they are usually discretized on an underlying grid. The Components responsible for regridding and transferring data between Gridded Components are called Coupler Components. Each Component is associated with an Import and an Export State. Components can be nested so that simpler Components are contained within more complex ones.

Underlying these data classes are native language arrays. ESMF allows you to reference an existing Fortran array to an ESMF Array or Field so that ESMF data classes can be readily introduced into existing code. You can perform communication operations directly on Fortran arrays through the VM class, which serves as a unifying wrapper for distributed and shared memory communication libraries.

### 6.5 ESMF Spatial Classes

Like the hierarchy of model data classes, ranging from the simple to the complex, ESMF is organized around an hierarchy of classes that represent different spaces associated with a computation. Each of these spaces can be manipulated, in order to give the user control over how a computation is executed. For Earth system models, this hierarchy starts with the address space associated with the computer and extends to the physical region described by the application. The main spatial classes in ESMF, from those closest to the machine to those closest to the application, are:

• **The Virtual Machine**, or VM The ESMF VM is an abstraction of a parallel computing environment that encompasses both shared and distributed memory, single and multi-core systems. Its primary purpose is resource allocation and management. Each Component runs in its own VM, using the resources it defines. The elements of a VM are **Persistent Execution Threads**, or PETs, that are executing in **Virtual Address Spaces**, or VASs. A simple case is one in which every PET is associated with a single MPI process. In this case every PET is executing in its own private VAS. If Components are nested, the parent component allocates a subset of its PETs to its children. The children have some flexibility, subject to the constraints of the computing environment, to decide how they want to use the resources associated with the PETs they’ve received.

• **DELayout** A DELayout represents a data decomposition (we also refer to this as a distribution). Its basic elements are **Decomposition Elements**, or DEs. A DELayout associates a set of DEs with the PETs in a VM. DEs are not necessarily one-to-one with PETs. For cache blocking, or user-managed multi-threading, more DEs than PETs may be defined. Fewer DEs than PETs may also be defined if an application requires it.

• **DistGrid** A DistGrid represents the index space associated with a grid. It is a useful abstraction because often a full specification of grid coordinates is not necessary to define data communication patterns. The DistGrid contains information about the sequence and connectivity of data points, which is sufficient information for many operations. Arrays are defined on DistGrids.

• **Array** An Array defines how the index space described in the DistGrid is associated with the VAS of each PET. This association considers the type, kind and rank of the indexed data. Fields are defined on Arrays.

• **Grid** A Grid is an abstraction of a physical space. It associates a coordinate system, a set of coordinates, and a topology to a collection of grid cells. Grids in ESMF are comprised of DistGrids plus additional coordinate information.
• **Field** A Field may contain more dimensions than the Grid that it is discretized on. For example, for convenience during integration, a user may want to define a single Field object that holds snapshots of data at multiple times. Fields also keep track of the stagger location of a Field data point within its associated Grid cell.

### 6.6 ESMF Maps

In order to define how the index spaces of the spatial classes relate to each other, we require either implicit rules (in which case the relationship between spaces is defined by default), or special Map arrays that allow the user to specify the desired association. The form of the specification is usually that the position of the array element carries information about the first object, and the value of the array element carries information about the second object. ESMF includes a `distGridToArrayMap`, a `gridToFieldMap`, a `distGridToGridMap`, and others.

### 6.7 ESMF Specification Classes

It can be useful to make small packets of descriptive parameters. ESMF has one of these:

- **ArraySpec**, for storing the specifics, such as type/kind/rank, of an array.

### 6.8 ESMF Utility Classes

There are a number of utilities in ESMF that can be used independently. These are:

- **Attributes**, for storing metadata about Fields, FieldBundles, States, and other classes.
- **TimeMgr**, for calendar, time, clock and alarm functions.
- **LogErr**, for logging and error handling.
- **Config**, for creating resource files that can replace namelists as a consistent way of setting configuration parameters.

### 7 Integrating ESMF into Applications

Depending on the requirements of the application, the user may want to begin integrating ESMF in either a top-down or bottom-up manner. In the top-down approach, tools at the superstructure level are used to help reorganize and structure the interactions among large-scale components in the application. It is appropriate when interoperability is a primary concern; for example, when several different versions or implementations of components are going to be swapped in, or a particular component is going to be used in multiple contexts. Another reason for deciding on a top-down approach is that the application contains legacy code that for some reason (e.g., intertwined functions, very large, highly performance-tuned, resource limitations) there is little motivation to fully restructure. The superstructure can usually be incorporated into such applications in a way that is non-intrusive.

In the bottom-up approach, the user selects desired utilities (data communications, calendar management, performance profiling, logging and error handling, etc.) from the ESMF infrastructure and either writes new code using them, introduces them into existing code, or replaces the functionality in existing code with them. This makes sense when maximizing code reuse and minimizing maintenance costs is a goal. There may be a specific need for functionality or the component writer may be starting from scratch. The calendar management utility is a popular place to start.
7.1 Using the ESMF Superstructure

The following is a typical set of steps involved in adopting the ESMF superstructure. The first two tasks, which occur before an ESMF call is ever made, have the potential to be the most difficult and time-consuming. They are the work of splitting an application into components and ensuring that each component has well-defined stages of execution. ESMF aside, this sort of code structure helps to promote application clarity and maintainability, and the effort put into it is likely to be a good investment.

1. Decide how to organize the application as discrete Gridded and Coupler Components. This might involve reorganizing code so that individual components are cleanly separated and their interactions consist of a minimal number of data exchanges.

2. Divide the code for each component into initialize, run, and finalize methods. These methods can be multi-phase, e.g., init_1, init_2.

3. Pack any data that will be transferred between components into ESMF Import and Export State data structures. This is done by first wrapping model data in either ESMF Arrays or Fields. Arrays are simpler to create and use than Fields, but carry less information and have a more limited range of operations. These Arrays and Fields are then added to Import and Export States. They may be packed into ArrayBundles or FieldBundles first, for more efficient communications. Metadata describing the model data can also be added. At the end of this step, the data to be transferred between components will be in a compact and largely self-describing form.

4. Pack time information into ESMF time management data structures.

5. Using code templates provided in the ESMF distribution, create ESMF Gridded and Coupler Components to represent each component in the user code.

6. Write a set services routine that sets ESMF entry points for each user component’s initialize, run, and finalize methods.

7. Run the application using an ESMF Application Driver.

8 Overall Rules and Behavior

8.1 Local and Global Views and Associated Conventions

ESMF data objects such as Fields are distributed over DEs, with each DE getting a portion of the data. Depending on the task, a local or global view of the object may be preferable. In a local view, data indices start with the first element on the DE and end with the last element on the same DE. In a global view, there is an assumed or specified order to the set of DEs over which the object is distributed. Data indices start with the first element on the first DE, and continue across all the elements in the sequence of DEs. The last data index represents the number of elements in the entire object. The DistGrid provides the mapping between local and global data indices.

The convention in ESMF is that entities with a global view have no prefix. Entities with a DE-local (and in some cases, PET-local) view have the prefix “local.”

Just as data is distributed over DEs, DEs themselves can be distributed over PETs. This is an advanced feature for users who would like to create multiple local chunks of data, for algorithmic or performance reasons. Local DEs are those DEs that are located on the local PET. Local DE labeling always starts at 0 and goes to localDeCount-1, where localDeCount is the number of DEs on the local PET. Global DE numbers also start at 0 and go to deCount-1. The DELayout class provides the mapping between local and global DE numbers.
8.2 Allocation Rules

The basic rule of allocation and deallocation for the ESMF is: whoever allocates it is responsible for deallocating it. ESMF methods that allocate their own space for data will deallocate that space when the object is destroyed. Methods which accept a user-allocated buffer, for example ESMF_FieldCreate() with the ESMF_DATACOPY_REFERENCE flag, will not deallocate that buffer at the time the object is destroyed. The user must deallocate the buffer when all use of it is complete.

Classes such as Fields, FieldBundles, and States may have Arrays, Fields, Grids and FieldBundles created externally and associated with them. These associated items are not destroyed along with the rest of the data object since it is possible for the items to be added to more than one data object at a time (e.g. the same Grid could be part of many Fields). It is the user’s responsibility to delete these items when the last use of them is done.

8.3 Assignment, Equality, Copying and Comparing Objects

The equal sign assignment has not been overloaded in ESMF, thus resulting in the standard Fortran behavior. This behavior has been documented as the first entry in the API documentation section for each ESMF class. For deep ESMF objects the assignment results in setting an alias the the same ESMF object in memory. For shallow ESMF objects the assignment is essentially equivalent to a copy of the object. For deep classes the equality operators have been overloaded to test for the alias condition as a counter part to the assignment behavior. This and the not equal operator are documented following the assignment in the class API documentation sections.

Deep object copies are implemented as a special variant of the ESMF_<Class>Create() methods. It takes an existing deep object as one of the required arguments. At this point not all deep classes have ESMF_<Class>Create() methods that allow object copy.

Due to the complexity of deep classes there are many aspects when comparing two objects of the same class. ESMF provide ESMF_<Class>Match() methods, which are functions that return a class specific match flag. At this point not all deep classes have ESMF_<Class>Match() methods that allow deep object comparison.

8.4 Attributes

Attributes are (name, value) pairs, where the name is a character string and the value can be either a single value or list of integer, real, double precision, logical, or character values. Attributes can be associated with Fields, FieldBundles, and States. Mixed types are not allowed in a single attribute, and all attribute names must be unique within a single object. Attributes are set by name, and can be retrieved either directly by name or by querying for a count of attributes and retrieving names and values by index number.

8.5 Constants

Named constants are used throughout ESMF to specify the values of many arguments with multiple well defined values in a consistent way. These constants are defined by a derived type that follows this pattern:

```fortran
ESMF_<CONSTANT_NAME>_Flag
```

The values of the constant are then specified by this pattern:

```fortran
ESMF_<CONSTANT_NAME>_<VALUE1>
```
A master list of all available constants can be found in section 50.

9 Overall Design and Implementation Notes

1. **Deep and shallow classes.** The deep and shallow classes described in Section 6.2 differ in how and where they are allocated within a multi-language implementation environment. We distinguish between the implementation language, which is the language a method is written in, and the calling language, which is the language that the user application is written in. Deep classes are allocated off the process heap by the implementation language. Shallow classes are allocated off the stack by the calling language.

2. **Base class.** All ESMF classes are built upon a Base class, which holds a small set of system-wide capabilities.

10 Overall Restrictions and Future Work

1. **32-bit integer limitations.** In general, Fortran array bounds should be limited to \(2^{31}-1\) elements or less. This is due to the Fortran-95 limitation of returning default sized (e.g., 32 bit) integers for array bound and size inquiries, and consequent ESMF use of default sized integers for holding these values.
Part II

Applications

The main product delivered by ESMF is the ESMF library that allows application developers to write programs based on the ESMF API. In addition to the programming library, ESMF distributions come with a small set of applications that are of general interest to the community. These applications utilize the ESMF library to implement features such as printing general information about the ESMF installation, or generating regrid weight files. The provided ESMF applications are intended to be used as standard command line tools.

The bundled ESMF applications are built and installed during the usual ESMF installation process, which is described in detail in the ESMF User’s Guide section "Building and Installing the ESMF". After the installation the applications will be located in the ESMF_APPSDIR directory, which can be found as a Makefile variable in the esmf.mk file. The esmf.mk file can be found in the ESMF_INSTALL_LIBDIR directory after a successful installation. The ESMF User’s Guide discusses the esmf.mk mechanism to access the bundled applications in more detail in section "Using Bundled ESMF Applications".

The following sections provide in-depth documentation of the bundled ESMF applications. In addition, each application supports the standard \texttt{--help} command line argument, providing a brief description of how to invoke the program.

11 ESMF_Info

11.1 Description

The ESMF_Info application prints basic information about the ESMF installation to \texttt{stdout}.

The application usage is as follows:

\texttt{ESMF_Info \[--help\]}

where

\texttt{--help} prints a brief usage message

12 ESMF_RegridWeightGen

12.1 Description

This section describes the offline regrid weight generation application provided by ESMF (for a description of ESMF regridding in general see Section 23.2). Regridding, also called remapping or interpolation, is the process of changing the grid that underlies data values while preserving qualities of the original data. Different kinds of transformations are appropriate for different problems. Regridding may be needed when communicating data between Earth system model components such as land and atmosphere, or between different data sets to support operations such as visualization.

Regridding can be broken into two stages. The first stage is generation of an interpolation weight matrix that describes how points in the source grid contribute to points in the destination grid. The second stage is the multiplication of
values on the source grid by the interpolation weight matrix to produce values on the destination grid. This occurs through a parallel sparse matrix multiply.

There are two options for accessing ESMF regridding functionality: integrated and offline. Integrated regridding is a process whereby interpolation weights are generated via subroutine calls during the execution of the user’s code. The integrated regridding can also perform the parallel sparse matrix multiply. In other words, ESMF integrated regridding allows a user to perform the whole process of interpolation within their code. For a further description of ESMF integrated regridding please see Section 25.3.24. In contrast to integrated regridding, offline regridding is a process whereby interpolation weights are generated by a separate ESMF application, not within the user code. The ESMF offline regridding application also only generates the interpolation matrix, the user is responsible for reading in this matrix and doing the actual interpolation (multiplication by the sparse matrix) in their code. The rest of this section further describes ESMF offline regridding.

For a discussion of installing and accessing ESMF applications such as this one please see the beginning of this part of the reference manual (Section I) or for the quickest approach to just building and accessing the applications please refer to the “Building and using bundled ESMF applications” Section in the ESMF User’s Guide.

As described above, this tool reads in two grid files and outputs weights for interpolation between the two grids. The input and output files are all in NetCDF format. The grid files can be defined in four different formats: the SCRIP format as is used as an input to SCRIP, the GRIDSPEC Tile grid file following the CF metadata conventions, the ESMF unstructured grid format or the proposed CF unstructured grid data model (UGRID) in the current ESMF release. GRIDSPEC is a proposed CF extension for the annotation of complex Earth system grids. In the current ESMF release, we only support a single tile grid file for rectangular lat/lon grid. For UGRID, we support the 2D flexible mesh topology with mixed triangles and quadrilaterals and fully 3D unstructured mesh topology with hexahedrons and tetrahedrons.

The weight file is the same format as is output by SCRIP. The interpolation weights can be generated with the bilinear, patch, or first order conservative methods described below. Masking is supported for 2D logically rectangular (i.e. with grid_rank=2) grids in the SCRIP format. This application can do regrid weight generation from a global or regional source grid to a global or regional destination grid. It assumes that the source and destination grids are on a sphere and that the coordinates given in the files are latitude and longitude values. The coordinates can either be in degrees or radians (this is indicated by the "units" attribute attached to the value). As is true with many global models, this application currently assumes the latitude and longitude refer to positions on a perfect sphere, as opposed to a more complex and accurate representation of the earth’s true shape such as would be used in a GIS system. (ESMF’s current user base doesn’t require this level of detail in representing the earth’s shape, but it could be added in the future if necessary.) This file based regrid weight generation application is parallel.

This application requires the NetCDF library to read the grid files and to write out the weight files in NetCDF format. To compile ESMF with the NetCDF library, please refer to the "Third Party Libraries" Section in the ESMF User’s Guide for more information.

Internally this application uses the ESMF public API to generate the interpolation weights. If a source or destination grid is logically rectangular, then ESMF_GridCreate() is used to create an ESMF_Grid object. The cell center coordinates of the input grid are put into the center stagger location (ESMF_STAGGERLOC_CENTER). In addition, the corner coordinates are also put into the corner stagger location (ESMF_STAGGERLOC_CORNER) for conservative regridding. The method ESMF_MeshCreate() is used to create an ESMF_Mesh object, if the source or destination grid is a cubed sphere grid or an unstructured grid. When making this call, the flag convert3D is set to TRUE to convert the 2D coordinates into 3D Cartesian coordinates. Currently, ESMF only supports triangle or quadrilateral element types for a 2D Mesh. Therefore, when the cells in an unstructured grid contain more than four edges, they are broken into multiple triangle elements before ESMF_MeshCreate() is called to create the ESMF_Mesh object. After the calculation of the weight matrix based on the broken up cells, the matrix entries for the triangles are merged together, so that the output matrix is in terms of the original cells. Internally ESMF_FieldRegridStore() is used to generate the weight table and indices table representing the interpolation
The regridding occurs in 3D to avoid problems with periodicity and with the pole singularity. This application supports four options for handling the pole region (i.e. the empty area above the top row of the source grid or below the bottom row of the source grid). Note that all of these pole options currently only work for logically rectangular grids (i.e. SCRIP format grids with grid_rank=2 or GRIDSPEC format grids). The first option is to leave the pole region empty ("-p none"), in this case if a destination point lies above or below the top row of the source grid, it will fail to map, yielding an error (unless "-i" is specified). With the next two options, the pole region is handled by constructing an artificial pole in the center of the top and bottom row of grid points and then filling in the region from this pole to the edges of the source grid with triangles. The pole is located at the average of the position of the points surrounding it, but moved outward to be at the same radius as the rest of the points in the grid. The difference between these two artificial pole options is what value is used at the pole. The default pole option ("-p all") sets the value at the pole to be the average of the values of all of the grid points surrounding the pole. For the other option ("-p N"), the user chooses a number N from 1 to the number of source grid points around the pole. For each destination point, the value at the pole is then the average of the N source points surrounding that destination point. For the last pole option ("-p teeth") no artificial pole is constructed, instead the pole region is covered by connecting points across the top and bottom row of the source Grid into triangles. As this makes the top and bottom of the source sphere flat, for a big enough difference between the size of the source and destination pole regions, this can still result in unmapped destination points. Only pole option "none" is currently supported with the conservative interpolation method ("-m conserve") and with the nearest neighbor interpolation methods ("-m nearestdtos" and "-m neareststod").

Masking is supported for both the logically rectangular grids and the unstructured grids. If the grid file is in the SCRIP format, the variable "grid_imask" is used as the mask. If the value is set to 0 for a grid point, then that point is considered masked out and won’t be used in the weights generated by the application. If the grid file is in the ESMF format, the variable "elementMask" is used as the mask. For a grid defined in the GRIDSPEC Tile grid or in the UGRID convention, there is no mask variable defined. However, a GRIDSPEC or a UGRID file may contain both the grid definition and the data. The grid mask is usually constructed using the missing values defined in the data variable. The regridding application provides the argument "--src_missingvalue" or "--dst_missingvalue" for users to specify the variable name from where the mask can be constructed.

If a destination point can’t be mapped because it falls outside the unmasked source grid, then the default behavior of the application is to stop with an error. By specifying "-i" or the equivalent "--ignore_unmapped" the user can cause the application to ignore unmapped destination points. In this case, the output matrix won’t contain entries for the unmapped destination points. Note, that the unmapped point detection doesn’t currently work for nearest destination to source method ("-m nearestdtos"), so when using that method it is as if "-i" is always on.

This regridding application can be used to generate bilinear, patch, nearest neighbor, or first-order conservative interpolation weights. The following is a description of these interpolation methods as relevant to the offline weight generation application, for a more in-depth description see Section 23.2.

The default interpolation method for the weight generation application is bilinear. The algorithm used by this application to generate the bilinear weights is the standard one found in many textbooks. Each destination point is mapped to a location in the source Mesh, the position of the destination point relative to the source points surrounding it is used to calculate the interpolation weights.

This application can also be used to generate patch interpolation weights. Patch interpolation is the ESMF version of a technique called "patch recovery" commonly used in finite element modeling [6] [13]. It typically results in better approximations to values and derivatives when compared to bilinear interpolation. Patch interpolation works by constructing multiple polynomial patches to represent the data in a source element. For 2D grids, these polynomials are currently 2nd degree 2D polynomials. The interpolated value at the destination point is the weighted average of the values of the patches at that point.

The patch interpolation process works as follows. For each source element containing a destination point we construct a patch for each corner node that makes up the element (e.g. 4 patches for quadrilateral elements, 3 for triangular
To construct a polynomial patch for a corner node we gather all the elements around that node. (Note that this means that the patch interpolation weights depends on the source element’s nodes, and the nodes of all elements neighboring the source element.) We then use a least squares fitting algorithm to choose the set of coefficients for the polynomial that produces the best fit for the data in the elements. This polynomial will give a value at the destination point that fits the source data in the elements surrounding the corner node. We then repeat this process for each corner node of the source element generating a new polynomial for each set of elements. To calculate the value at the destination point we do a weighted average of the values of each of the corner polynomials evaluated at that point. The weight for a corner’s polynomial is the bilinear weight of the destination point with regard to that corner. The patch method has a larger stencil than the bilinear, for this reason the patch weight matrix can be correspondingly larger than the bilinear matrix (e.g. for a quadrilateral grid the patch matrix is around 4x the size of the bilinear matrix). This can be an issue when performing a regrid weight generation operation close to the memory limit on a machine.

The nearest neighbor interpolation options work by associating a point in one set with the closest point in another set. If two points are equally close then the point with the smallest index is arbitrarily used (i.e. the point with that would have the smallest index in the weight matrix). There are two versions of this type of interpolation available in the regrid weight generation application. One of these is the nearest source to destination method ("-m neareststod"). In this method each destination point is mapped to the closest source point. The other of these is the nearest destination to source method ("-m nearestdtsd"). In this method each source point is mapped to the closest destination point. Note, that with this method the unmapped destination point detection doesn’t work, so no error will be returned even if there destination points which don’t map to any source point.

First-order conservative interpolation [22] is also available as a regridding method. This method will typically have a larger local interpolation error than the previous two methods, but will do a much better job of preserving the value of the integral of data between the source and destination grid. In this method the value across each source cell is treated as a constant. The weights for a particular destination cell are the area of intersection of each source cell with the destination cell divided by the area of the destination cell. Areas in this case are calculated by connecting the corner coordinates of each grid cell (obtained from the grid file) with great circles. If the user doesn’t specify the user area’s option ("-a --user_areas"), then the conservation will hold for the great circle areas calculated by ESMF (and these are output to the weight file). This means the following equation will hold: \( \sum_{all-destination-cells} (V_{dj} \times A'_{dj}) = \sum_{all-source-cells} (V_{si} \times A_{si}) \) where \( V \) is the variable being regridded and \( A' \) is the area of a cell as calculated by ESMF. The subscripts s and d refer to source and destination values, and the i and j are the source and destination grid cell indices (flattening the arrays to 1 dimension). If the user does specify the user area’s option, then the conservation will be adjusted to work for the areas provided by the user in the grid files (and these areas are output to the weight file). This means the following equation will hold: \( \sum_{all-source-cells} (V_{si} \times A_{si}) = \sum_{all-destination-cells} (V_{dj} \times A_{dj}) \), where \( A \) is the area of a cell as provided by the user.

Note that since the conservative assumes great circle edges to cells, the edges of a cell won’t necessarily be the same as a straight line in latitude longitude. For small edges, this difference will be small, but for long edges it could be significant. This means if the user expects cell edges as straight lines in latitude longitude space, they should avoid using one large cell with long edges to compute an average over a region (e.g. over an ocean basin). The user should also avoid using cells which contain one edge that runs half way or more around the earth, because the regrid weight calculation assumes the edge follows the shorter great circle path. Also, there isn’t a unique great circle edge defined between points on the exact opposite side of the earth from one another (antipodal points). However, the user can work around both of these problem by breaking the long edge into two smaller edges by inserting an extra node, or by breaking the large target grid cells into two or more smaller grid cells. This allows the application to resolve the ambiguity in edge direction. One other unexpected case which might cause problems is a grid containing a concave cell with exactly four sides, this will cause the application to return an error. The application will work for a grid containing concave cells as long as all of them have more than four sides.

It is important to note that the current implementation of conservative regridding doesn’t normalize the interpolation weights by the destination fraction. This means that for a destination grid which only partially overlaps the source grid the destination field which is output from the regrid operation should be divided by the corresponding destination fraction to yield the true interpolated values for cells which are only partially covered by the source grid. The fraction...
also needs to be included when computing the total source and destination integrals.

The following pseudo-code shows how to adjust a destination field \((\text{dst\_field})\) by the destination fraction \((\text{dst\_frac})\) called \(\text{frac\_b}\) in the weight file:

\[
\text{for each destination element } i \\
\quad \text{if (dst\_frac}(i) \text{ not equal to } 0.0) \text{ then} \\
\quad \quad \text{dst\_field}(i)=\text{dst\_field}(i)/\text{dst\_frac}(i) \\
\quad \text{end if} \\
\text{end for}
\]

The following pseudo-code shows how to compute the total destination integral \((\text{dst\_total})\) given the destination field values \((\text{dst\_field})\) resulting from the sparse matrix multiply of the weights in the weight file by the source field, the destination area \((\text{dst\_area})\) called \(\text{area\_b}\) in the weight file, and the destination fraction \((\text{dst\_frac})\) called \(\text{frac\_b}\) in the weight file. As in the previous paragraph, it also shows how to adjust the destination field \((\text{dst\_field})\) resulting from the sparse matrix multiply by the fraction \((\text{dst\_frac})\) called \(\text{frac\_b}\) in the weight file:

\[
\text{dst\_total}=0.0 \\
\text{for each destination element } i \\
\quad \text{if (dst\_frac}(i) \text{ not equal to } 0.0) \text{ then} \\
\quad \quad \text{dst\_total}=\text{dst\_total}+\text{dst\_field}(i)\times\text{dst\_area}(i) \\
\quad \quad \text{dst\_field}(i)=\text{dst\_field}(i)/\text{dst\_frac}(i) \\
\quad \quad \text{! If mass computed here after dst\_field adjust, would need to be:} \\
\quad \quad \text{! dst\_total}=\text{dst\_total}+\text{dst\_field}(i)\times\text{dst\_area}(i)\times\text{dst\_frac}(i) \\
\quad \quad \text{end if} \\
\text{end for}
\]

The following pseudo-code shows how to compute the total source integral \((\text{src\_total})\) given the source field values \((\text{src\_field})\), the source area \((\text{src\_area})\) called \(\text{area\_a}\) in the weight file, and the source fraction \((\text{src\_frac})\) called \(\text{frac\_a}\) in the weight file:

\[
\text{src\_total}=0.0 \\
\text{for each source element } i \\
\quad \text{src\_total}=\text{src\_total}+\text{src\_field}(i)\times\text{src\_area}(i)\times\text{src\_frac}(i) \\
\text{end for}
\]

The interpolation weights generated by this application are output to a NetCDF file (specified by the "-w" or "--weight" keywords). The format of this file is the same as that generated by SCRIP. See Section 12.8 for a description of the format. Note that the sequence of the weights in the file can vary with the number of processors used to run the application. This means that two weight files generated by using different numbers of processors can contain exactly the same interpolation matrix, but can appear different in a direct line by line comparison (such as would be done by ncdiff).

### 12.2 Usage

The command line arguments are all keyword based. Both the long keyword prefixed with ‘--’ or the one character short keyword prefixed with ‘-’ are supported. The format to run the application is as follows:
ESMF_RegridWeightGen

[--help]

[--version]
[--source|-s] src_grid_filename
[--destination|-d] dst_grid_filename
[--weight|-w] out_weight_file
[--method|-m] [bilinear|patch|neareststod|neareststod|conserve]
[--pole|-p] [none|all|teeth|1|2|..]
[--ignore_unmapped|-i]
--src_type [SCRIP|GRIDSPEC|ESMF|UGRID]
--dst_type [SCRIP|GRIDSPEC|ESMF|UGRID]
-t [SCRIP|GRIDSPEC|ESMF|UGRID]
-r
--src_regional
--dst_regional
--64bit_offset
--netcdf4
--src_meshname dummy_var_name
--dst_meshname dummy_var_name
--src_missingvalue var_name
--dst_missingvalue var_name
--dst_coordinates lon_name,lat_name
--dst_coordinates lon_name,var_name
--user_areas
--check

where
--help - Print the usage message and exit.
--version - Print ESMF version and license information and exit.
--source or -s - a required argument specifying the source grid file name

--destination or -d - a required argument specifying the destination grid file name

--weight or -w - a required argument specifying the output regridding weight file name

--method or -m - an optional argument specifying which interpolation method is used. The value can be one of the following:

  bilinear - for bilinear interpolation, also the default method if not specified.
  patch - for patch recovery interpolation
  conserve - for first-order conservative interpolation

--pole or -p - an optional argument indicating what to do with the pole.
The value can be one of the following:

  none - No pole, the source grid ends at the top (and bottom) row of nodes specified in
all - Construct an artificial pole placed in the center of the top (or bottom) row of nodes, but projected onto the sphere formed by the rest of the grid. The value at this pole is the average of all the pole values. This is the default option.

teeth - No new pole point is constructed, instead the holes at the poles are filled by constructing triangles across the top and bottom row of the source grid. This can be useful because no averaging occurs, however, because the top and bottom of the sphere are now flat, for a big enough mismatch between the size of the destination and source pole regions, some destination points may still not be able to be mapped to the source grid.

<N> - Construct an artificial pole placed in the center of the top (or bottom) row of nodes, but projected onto the sphere formed by the rest of the grid. The value at this pole is the average of the N source nodes next to the pole and surrounding the destination point (i.e. the value may differ for each destination point. Here N ranges from 1 to the number of nodes around the pole.

--ignore_unmapped or -i - ignore unmapped destination points. If not specified the default is to stop with an error if an unmapped point is found.

--src_type - an optional argument specifying the source grid file type. The value could be one of SCRIP, GRIDSPEC, ESMF or UGRID. The SCRIP file can be either structured or unstructured grid. The GRIDSPEC is the only for the structured grid defined in the CF convention. The ESMF and UGRID file types are only available for the unstructured grid. The default option is SCRIP.

--dst_type - an optional argument specifying the destination grid file type. The value could be one of SCRIP, GRIDSPEC, ESMF or UGRID. The SCRIP file can be either structured or unstructured grid. The GRIDSPEC is the only for the structured grid defined in the CF convention. UGRID. The ESMF and UGRID file types are only available for the unstructured grid. The default option is SCRIP.
-t - an optional argument specifying the file types for both the source and the destination grid files. The default option is SCRIP. If both -t and --src_type or --dst_type are given at the same time and they disagree with each other, an error message will be generated.

-r - an optional argument specifying that the source and destination grids are regional grids. If the argument is not given, the grids are assumed to be global.

--src_regional - an optional argument specifying that the source is a regional grid and the destination is a global grid.

--dst_regional - an optional argument specifying that the destination is a regional grid and the source is a global grid.

--64bit_offset - an optional argument specifying that the weight file will be created in the NetCDF 64-bit offset format to allow variables larger than 2GB. Note the 64-bit offset format is not supported in the NetCDF version earlier than 3.6.0. An error message will be generated if this flag is specified while the application is linked with a NetCDF library earlier than 3.6.0.

--netcdf4 - an optional argument specifying that the output weight file will be created in the NetCDF4 format. This option only works with NetCDF library version 4.1 and above that was compiled with the NetCDF4 file format enabled (with HDF5 compression). An error message will be generated if these conditions are not met.

--src_meshname - this argument is required if the source grid type is UGRID. It defines the dummy variable name that has all the topology information stored in its attributes.

--dst_meshname - this argument is required if the destination grid type is UGRID. It defines the dummy variable name that has all the topology information stored in its attributes.

--src_missingvalue - an optional argument that defines the variable name in the source grid file if the file type is GRIDSPEC or UGRID. The regridder will generate a mask using the missing values of the data variable. The missing value is defined using an attribute called "_FillValue" or "missing_value".

--dst_missingvalue - an optional argument that defines the variable name in the destination grid file if the file type is GRIDSPEC or UGRID. The regridder will generate a mask using the missing values of the data variable. The missing value is defined using an attribute called "_FillValue".
or "missing_value"

  --src_coordinates - an optional argument that defines the longitude and
latitude variable names in the source grid file if
the file type is GRIDSPEC. The variable names are
separated by comma. This argument is required in case
there are multiple sets of coordinate variables defined
in the file. Without this argument, the offline regrid
application will terminate with an error message when
multiple coordinate variables are found in the file.

  --dst_coordinates - an optional argument that defines the longitude and
latitude variable names in the destination grid file
if the file type is GRIDSPEC. The variable names are
separated by comma. This argument is required in case
there are multiple sets of coordinate variables defined
in the file. Without this argument, the offline regrid
application will terminate with an error message when
multiple coordinate variables are found in the file.

  --user_areas - an optional argument specifying that the conservation
is adjusted to hold for the user areas provided in
the grid files. If not specified, then the
conservation will hold for the ESMF calculated
(great circle) areas.
Whichever areas the conservation holds for are output
to the weight file.

  --check - Check that the generated weights produce reasonable regridded
fields. This is done by calling ESMF_Regrid() on an analytic
source field using the weights generated by this application.
The mean relative error between the destination and analytic
field is computed, as well as the relative error between the
mass of the source and destination fields in the conservative
case.

12.3 Examples

The example below shows the command to generate a set of conservative interpolation weights between a global
SCRIP format source grid file (src.nc) and a global SCRIP format destination grid file (dst.nc). The weights are written
into file w.nc. In this case the ESMF library and applications have been compiled using an MPI parallel communication
library (e.g. setting ESMF_COMM to openmpi) to enable it to run in parallel. To demonstrate running in parallel the
mpirun script is used to run the application in parallel on 4 processors.

  mpirun -np 4 ./ESMF_RegridWeightGen -s src.nc -d dst.nc -m conserve -w w.nc
The next example below shows the command to do the same thing as the previous example except for three changes. The first change is this time the source grid is regional ("--src_regional"). The second change is that for this example bilinear interpolation ("-m bilinear") is being used. Because bilinear is the default, we could also omit the "-m bilinear". The third change is that in this example some of the destination points are expected to not be found in the source grid, but the user is ok with that and just wants those points to not appear in the weight file instead of causing an error ("-i").

```
mpirun -np 4 ./ESMF_RegridWeightGen -i --src_regional -s src.nc -d dst.nc \
   -m bilinear -w w.nc
```

The default grid file format is SCRIP, to use a grid file in another grid format, you need to use the switches "--src_type", "--dst_type" or "-t". For example, if the source grid is in UGRID format and the destination grid is in GRIDSPEC format, the command to run the application is:

```
mpirun -np 4 ./ESMF_RegridWeightGen -s src.nc -d dst.nc \
   -m conserve -w w.nc --src_type UGRID --dst_type GRIDSPEC \
   --src_meshname mesh_dummy
```

Since the source grid is a UGRID, an additional argument "--src_meshname" needs to be provided. This is the dummy variable used to define all the mesh topology information in the grid file.

The last example shows how to use the missing values of a data variable to generate the grid mask for a GRIDSPEC file, how to specify the coordinate variable names using "--src_coordinates" and use user defined area for the conservative regridding.

```
mpirun -np 4 ./ESMF_RegridWeightGen -s src.nc -d dst.nc -m conserve \
   -w w.nc --src_type GRIDSPEC --src_missingvalue datavar \
   --src_coordinates lon,lat --user_areas
```

In the above example, "datavar" is the variable name defined in the source grid that will be used to construct the mask using its missing values. In addition, "lon" and "lat" are the variable names for the longitude and latitude values, respectively.

### 12.4 SCRIP Grid File Format

A SCRIP format grid file is a NetCDF file for describing grids. This format is the same as is used by the SCRIP package, and so grid files which work with that package should also work here. SCRIP format files are capable of storing either 2D logically rectangular grids or 2D unstructured grids. The basic format for both of these grids is the same and they are distinguished by the value of the grid_rank variable. Logically rectangular grids have grid_rank set to 2, whereas unstructured grids have this variable set to 1.

The following is a sample header of a logically rectangular grid file:
The grid_size dimension is the total number of cells in the grid; grid_rank refers to the number of dimensions. In this case grid_rank is 2 for a 2D logically rectangular grid. The integer array grid_dims gives the number of grid cells along each dimension. The number of corners (vertices) in each grid cell is given by grid_corners. The grid corner coordinates need to be listed in an order such that the corners are in counter-clockwise order. Also, note that if your grid has a variable number of corners on grid cells, then you should set grid_corners to be the highest value and use redundant points on cells with fewer corners.

The integer array grid_imask is used to mask out grid cells which should not participate in the regridding. The array should by zero for any points that do not participate in the regridding and one for all other points. Coordinate arrays provide the latitudes and longitudes of cell centers and cell corners. The unit of the coordinates can be either "radians" or "degrees".

Here is a sample header from a SCRIP unstructured grid file:

```plaintext
netcdf ne4np4-pentagons {
  dimensions:
    grid_size = 866 ;
    grid_corners = 5 ;
    grid_rank = 1 ;
  variables:
    int grid_dims(grid_rank) ;
    double grid_center_lat(grid_size) ;
      grid_center_lat:units = "degrees" ;
    double grid_center_lon(grid_size) ;
      grid_center_lon:units = "degrees" ;
    double grid_corner_lon(grid_size, grid_corners) ;
      grid_corner_lon:units = "degrees" ;
    double grid_corner_lat(grid_size, grid_corners) ;
    grid_corner_lat:_FillValue = -9999. ;
}
```
The variables are the same as described above, however, here (grid_rank = 1). In this format there is no notion of which cells are next to which, so to construct the unstructured mesh the connection between cells is defined by searching for cells with the same corner coordinates. (e.g. the same grid_corner_lat and grid_corner_lon values).

Both the SCRIP grid file format and the SCRIP weight file format work with the SCRIP 1.4 tools.

12.5 ESMF Unstructured Grid File Format

ESMF supports a custom unstructured grid file format for describing meshes. This format is more compatible than the SCRIP format with the methods used to create an ESMF Mesh object, so less conversion needs to be done to create a Mesh. The ESMF format is thus more efficient than SCRIP when used with ESMF codes (e.g. the ESMF_RegridWeightGen application). However, this format doesn’t currently support conversion to a dual mesh which means that non-conservative regridding (e.g. Bilinear) is only supported on nodes.

The following is a sample header in the ESMF format followed by a description:

```netcdf mesh-esmf {
dimensions:
  nodeCount = 9 ;
  elementCount = 5 ;
  maxNodePElement = 4 ;
  coordDim = 2 ;
variables:
  double nodeCoords(nodeCount, coordDim);
    nodeCoords:units = "degrees" ;
  int elementConn(elementCount, maxNodePElement) ;
    elementConn:long_name = "Node Indices that define the element / connectivity";
    elementConn:_FillValue = -1 ;
  byte numElementConn(elementCount) ;
    numElementConn:long_name = "Number of nodes per element" ;
  double centerCoords(elementCount, coordDim) ;
    centerCoords:units = "degrees" ;
  double elementArea(elementCount) ;
    elementArea:units = "radians^2" ;
    elementArea:long_name = "area weights" ;
  int elementMask(elementCount) ;
    elementMask:_FillValue = -9999. ;
// global attributes:
  :gridType="unstructured";
  :version = "0.9" ;
```
In the ESMF format the netCDF dimensions have the following meanings. The \texttt{nodeCount} dimension is the number of nodes in the mesh. The \texttt{elementCount} dimension is the number of elements in the mesh. The \texttt{maxNodePElement} dimension is the maximum number of nodes in any element in the mesh. For example, in a mesh containing just triangles, then \texttt{maxNodePElement} would be 3. However, if the mesh contained one quadrilateral then \texttt{maxNodePElement} would need to be 4. The \texttt{coordDim} dimension is the number of dimensions of the points making up the mesh (i.e. the spatial dimension of the mesh). For example, a 2D planar mesh would have \texttt{coordDim} equal to 2.

In the ESMF format the netCDF variables have the following meanings. The \texttt{nodeCoords} variable contains the coordinates for each node. \texttt{nodeCoords} is a two-dimensional array of dimension \((\texttt{nodeCount,coordDim})\). For a 2D Grid, \texttt{coordDim} is 2 and the grid is assumed to be spherical. \texttt{nodeCoords(:,1)} contains the longitude coordinates and \texttt{nodeCoords(:,2)} contains the latitude coordinates. The same order applies to \texttt{centerCoords}. For a 3D Grid, \texttt{coordDim} is 3 and the grid is assumed to be Cartesian. \texttt{nodeCoords(:,1)} contains the \(x\) coordinates, \texttt{nodeCoords(:,2)} contains the \(y\) coordinates, and \texttt{nodeCoords(:,3)} contains the \(z\) coordinates. The same order applies to \texttt{centerCoords}.

The \texttt{elementConn} variable describes how the nodes are connected together to form each element. For each element (i.e. each iteration of the first dimension of the variable), this variable contains a list of 1-based indices into the \texttt{nodeCoords} variable pointing to the nodes which make up that element. For example, if \texttt{elementConn(2,1..3)} contains \((1,2,4)\), then that means that the second element consists of the nodes whose coordinates are described by \texttt{nodeCoords(1)}, \texttt{nodeCoords(2)}, and \texttt{nodeCoords(4)}. The order of the indices describing the element is important. The proper order for elements available in an ESMF mesh can be found in Section 32.2.1. The file format does support 2D polygons with more corners than those in that section, but internally these are broken into triangles. For these polygons, the corners should be listed such that they are in counter-clockwise order around the element. Because variables have to be rectangular, the second dimension of the \texttt{elementConn} variable has to be the size of the largest number of nodes in any element (i.e. \texttt{maxNodePElement}), the actual number of nodes in an element is given by the \texttt{numElementConn} variable. For a given dimension (i.e. \texttt{coordDim}) the number of nodes in the element indicates the element shape, for example in 2D, if \texttt{numElementConn} is 4 then the element is a quadrilateral. In 3D, if \texttt{numElementConn} is 8 then the element is a hexahedron.

The rest of the variables in the format are optional. The \texttt{centerCoords} variable gives the coordinates of the center of the corresponding element. This variable is currently not used by ESMF. The \texttt{elementArea} variable gives the area (or volume in 3D) of the corresponding element. This area is used by ESMF during conservative interpolation. If not specified, ESMF calculates the area (or volume) based on the coordinates of the nodes making up the element. The final variable is the \texttt{elementMask} variable. This variable allows the user to specify a mask value for the corresponding element. If the value is 1, then the element is unmasked and if the value is 0 the element is masked. If not specified, ESMF assumes that no elements are masked.

The following is a picture of a small example mesh and a sample ESMF format header using non-optional variables describing that mesh:

```
2.0 7 ------- 8 ------- 9
  |   |   |
  4 |   | 5 |
1.0 4 ------- 5 ------- 6
  |   |   |   |
  1 |   | \ 3 |
  \ |   |   |
0.0 1 ------- 2 ------- 3
  |   |   |   |
  |   | 2   |
  |   |\    |
0.0 1.0 2.0
```
12.6 CF Convention GRIDSPEC File Format

ESMF_RegridWeightGen supports NetCDF files that follow the CF GRIDSPEC convention for logically rectangular lat/lon grids.

GRIDSPEC is a draft proposal to extend the Climate and Forecast (CF) metadata conventions for the representation of
gridded data for Earth System Models. The original GRIDSPEC standard was proposed by V. Balaji and Z. Liang of GFDL. It was further developed by D. Kinley and A. Pletzer of Tech X (see ref). The ESMF implementation is based on the GRIDSPEC document last updated on 02/09/2012.

GRIDSPEC extends the current CF convention to support grid mosaics, i.e., a grid consisting of multiple logically rectangular grid tiles. It also provides a mechanism for storing a grid dataset in multiple files. Therefore, it introduces different types of files, such as a mosaic file that defines the multiple tiles and their connectivity, a host file that aggregates the grid mosaic and the data files, and a tile file for a single tile grid definition.

Currently, ESMF only supports the Grid creation and regridding from a single tile grid file. A tile file is a CF compliant NetCDF file for a logically rectangular lat/lon grid based on the CF Metadata Conventions V1.6. An example grid file is shown below. The cell center coordinate variables are determined by the value of its attribute units. The longitude variable has the attribute value set to either degrees_east, degree_east, degrees_E, degree_E, degreesE or degreeE. The latitude variable has the attribute value set to degrees_north, degree_north, degrees_N, degree_N, degreesN or degreeN. The latitude and the longitude variables are one-dimensional arrays if the grid is a regular lat/lon grid, two-dimensional arrays if the grid is curvilinear. The bound coordinate variables define the bound or the corner coordinates of a cell. The bound variable name is specified in the bounds attribute of the latitude and longitude variables. In the following example, the latitude bound variable is lat_bnds and the longitude bound variable is lon_bnds. The bound variables are 2D arrays for a regular lat/lon grid and a 3D array for a curvilinear grid. The first dimension of the bound array is 2 for a regular lat/lon grid and 4 for a curvilinear grid. The bound coordinates for a curvilinear grid is defined in counterclockwise order. In the example below, the grid is a regular lat/lon grid, thus the coordinate variables are 1D and the bound variables are 2D with the first dimension equal to 2. The bound coordinates will be read in and stored in a ESMF Grid object as the corner stagger coordinates when doing a conservative regrid. In case there are multiple sets of coordinate variables defined in a grid file, the offline regrid application will return an error for duplicate latitude or longitude variables unless the user uses "--src_coordinates" or "--src_coordinates" to specify the coordinate variable names to be used in the regrid.

Since a GRIDSPEC tile file does not have a way to specify the grid mask, the mask is usually derived by the missing values stored in a data variable. ESMF_RegridWeightGen provides an option for users to derive the grid mask from a data variable’s missing values. The value of the missing value is defined by the variable attribute missing_value or _FillValue. If the value of the data point is equal to the missing value, the grid mask for that grid point is set to 0, otherwise, it is set to 1. In the following grid, the variable so can be used to derive the grid mask. A data variable could be a 2D, 3D or 4D. For example, it may have additional depth and time dimensions. It is assumed that the first and the second dimensions of the data variable should be the longitude and the latitude dimension. ESMF_RegridWeightGen will use the first 2D data values to derive the grid mask.

```netcdf single_tile_grid {
  dimensions:
    time = 1 ;
    bound = 2 ;
    lat = 181 ;
    lon = 360 ;
  variables:
    double lat(lat) ;
    lat:bounds = "lat_bnds" ;
    lat:units = "degrees_north" ;
    lat:long_name = "latitude" ;
    lat:standard_name = "latitude" ;
    double lat_bnds(lat, bound) ;
    double lon(lon) ;
    lon:bounds = "lon_bnds" ;
```
12.7 CF Convention UGRID File Format

ESMF_RegridWeightGen supports NetCDF files that follow the UGRID conventions for unstructured grids.

The UGRID file format is a proposed extension to the CF metadata conventions for the unstructured grid data model. The latest proposal can be found at [https://github.com/ugrid-conventions/ugrid-conventions](https://github.com/ugrid-conventions/ugrid-conventions). The proposal is still evolving, the Mesh creation API and ESMF_RegridWeightGen in the current ESMF release is based on UGRID Version 0.9.0 published on October 29, 2013.

In the UGRID proposal, a 1D, 2D, or 3D mesh topology can be defined for an unstructured grid. Currently, ESMF supports two types of meshes: (1) the 2D flexible mesh topology where each cell (a.k.a. “face” as defined in the UGRID document) in the mesh is either a triangle or a quadrilateral, and (2) the fully 3D unstructured mesh topology where each cell (a.k.a. “volume” as defined in the UGRID document) in the mesh is either a tetrahedron or a hexahedron. Pyramids and wedges are not currently supported in ESMF, but they can be defined as degenerate hexahedrons.

The main addition of the UGRID extension is a dummy variable that defines the mesh topology. This additional variable has a required attribute cf_role with value “mesh_topology”. In addition, it has two more required attributes: topology_dimension and node_coordinates. If it is a 2D mesh (i.e., topology_dimension equals to 2), an additional attribute face_node_connectivity is required. If it is a 3D mesh (i.e., topology_dimension equals to 3), two additional attributes volume_node_connectivity and volume_shape_type are required. The value of attribute node_coordinates is a list of the names of the node longitude and latitude variables, plus the elevation variable if it is a 3D mesh. The value of attribute face_node_connectivity or volume_node_connectivity is the variable name that defines the corner node indices for each mesh cell. The additional attribute volume_shape_type for the 3D mesh points to a flag variable that specifies the shape type of each cell in the mesh.

12.7.1 2D UGRID Example

Below is a sample 2D mesh called FVCOM_grid2d. The dummy mesh topology variable is fvcom_mesh. As described above, its cf_role attribute has to be mesh_topology and topology_dimension attribute has to be 2 for a 2D mesh. It defines the node coordinate variable names to be lon and lat. It also specifies the face/node connectivity variable name as nv.

The variable nv is a two-dimensional array that defines the node indices of each face. The first dimension defines the maximal number of nodes for each face. In this example, it is a triangle mesh so the number of nodes per face is 3. Since each face may have different number of corner nodes, some of the cells may have fewer nodes than the specified dimension. In that case, it is filled with the missing values defined by the attribute _FillValue. The nodes are in counter clockwise order. An optional attribute start_index defines whether the node index is 1-based or 0-based.

The coordinate variables follows the CF metadata convention for coordinates. They are 1D array with attribute standard_name being either latitude or longitude. The units of the coordinates can be either degrees
The UGRID files may also contain data variables. The data may be located at the nodes or at the faces. Two additional attributes are introduced in the UGRID extension for the data variables: \textit{location} and \textit{mesh}. The \textit{location} attribute defines where the data is located, it can be either \textit{face} or \textit{node}. The \textit{mesh} attribute defines which mesh topology this variable belongs to since multiple mesh topologies may be defined in one file. The \textit{coordinates} attribute defined in the CF conventions can also be used to associate the variables to their locations. ESMF checks both \textit{location} and \textit{coordinates} attributes to determine where the data variable is defined upon. If both attributes are present, \textit{location} attribute takes the precedence. ESMF\textsubscript{RegridWeightGen} uses the data variable on the face to derive the element masks for the mesh cell and variable on the node to derive the node masks for the mesh.

When creating a ESMF Mesh from a UGRID file, user has to provide the mesh topology \textit{mesh} variable name to \texttt{ESMF\_MeshCreate()}. 

```netcdf
netcdf FVCOM_grid2d {
  dimensions:
    node = 417642 ;
    nele = 826866 ;
    three = 3 ;
    time = 1 ;
  variables:
    // Mesh topology
    int fvcom_mesh;
    fvcom_mesh:cf_role = "mesh_topology" ;
    fvcom_mesh:topology_dimension = 2. ;
    fvcom_mesh:node_coordinates = "lon lat" ;
    fvcom_mesh:face_node_connectivity = "nv" ;
    int nv(nele, three) ;
    nv:standard_name = "face_node_connectivity" ;
    nv:start_index = 1. ;
    // Mesh node coordinates
    float lon(node) ;
      lon:standard_name = "longitude" ;
      lon:units = "degrees_east" ;
    float lat(node) ;
      lat:standard_name = "latitude" ;
    lat:units = "degrees_north" ;
    // Data variable
    float ua(time, nele) ;
      ua:standard_name = "barotropic_eastward_sea_water_velocity" ;
      ua:missing_value = -999. ;
      ua:location = "face" ;
      ua:mesh = "fvcom_mesh" ;
    float va(time, nele) ;
      va:standard_name = "barotropic_northward_sea_water_velocity" ;
      va:missing_value = -999. ;
      va:location = "face" ;
      va:mesh = "fvcom_mesh" ;
}
```
12.7.2 3D UGRID Example

Following is a sample 3D UGRID file containing hexahedron cells. The dummy mesh topology variable is `fvcom_mesh`. Its `cf_role` attribute has to be `mesh_topology` and `topology_dimension` attribute has to be 3 for a 3D mesh. There are two additional required attributes: `volume_node_connectivity` specifies a variable name that defines the corner indices of the mesh cells and `volume_shape_type` specifies a variable name that defines the type of the mesh cells.

The node coordinates are defined by variables `nodelon`, `nodelat` and `height`. Currently, the units attribute for the `height` variable is either kilometers, km or meters. The variable `vertids` is a two-dimensional array that defines the corner node indices of each mesh cell. The first dimension defines the maximal number of nodes for each cell. There is only one type of cells in the sample grid, i.e. hexahedrons, so the maximal number of nodes is 8. The node order is defined in 12.2.1. The index can be either 1-based or 0-based and the default is 0-based. Setting an optional attribute `start_index` to 1 changed it to 1-based index scheme. The variable `meshtype` is a one-dimensional integer array that defines the shape type of each cell. Currently, ESMF only supports tetrahedron and hexahedron shapes. There are three attributes in `meshtype`: `flag_range`, `flag_values`, and `flag_meanings` representing the range of the flag values, all the possible flag values, and the meaning of each flag value, respectively. `flag_range` and `flag_values` are either a scaler or an array of integers. `flag_meanings` is a text string containing a list of shape types separated by space. In this example, there is only one shape type, thus, the values of `meshtype` are all 1.

```c
netcdf wam_ugrid100_110 {
    dimensions:
    nnodes = 78432 ;
    ncells = 66030 ;
    eight = 8 ;
    variables:
    int mesh ;
    mesh:cf_role = "mesh_topology" ;
    mesh:topology_dimension = 3. ;
    mesh:node_coordinates = "nodelon nodelat height" ;
    mesh:volume_node_connectivity = "vertids" ;
    mesh:volume_shape_type = "meshtype" ;
    double nodelon(nnodes) ;
    nodelon:standard_name = "longitude" ;
    nodelon:units = "degrees_east" ;
    double nodelat(nnodes) ;
    nodelat:standard_name = "latitude" ;
    nodelat:units = "degrees_north" ;
    double height(nnodes) ;
    height:standard_name = "elevation" ;
    height:units = "kilometers" ;
    int vertids(ncells, eight) ;
    vertids:cf_role = "volume_node_connectivity" ;
    vertids:start_index = 1. ;
    int meshtype(ncells) ;
    meshtype:cf_role = "volume_shape_type" ;
    meshtype:flag_range = 1. ;
    meshtype:flag_values = 1. ;
    meshtype:flag_meanings = "hexahedron" ;
}
```
12.8 Regrid Interpolation Weight File Format

The regridding weight output file is in NetCDF format and contains some grid information from each grid as well as the regridding indices and weights. Following is the header of a sample output weight file that was generated by regridding a logically rectangular 2D grid to a triangle mesh unstructured grid:

```plaintext
netcdf t42mpas-bilinear {
  dimensions:
  n_a = 8192 ;
  n_b = 20480 ;
  n_s = 42456 ;
  nv_a = 4 ;
  nv_b = 3 ;
  num_wgts = 1 ;
  src_grid_rank = 2 ;
  dst_grid_rank = 1 ;
  variables:
    int src_grid_dims(src_grid_rank) ;
    int dst_grid_dims(dst_grid_rank) ;
    double yc_a(n_a) ;
    yc_a:units = "degrees" ;
    double yc_b(n_b) ;
    yc_b:units = "radians" ;
    double xc_a(n_a) ;
    xc_a:units = "degrees" ;
    double xc_b(n_b) ;
    xc_b:units = "radians" ;
    double yv_a(n_a, nv_a) ;
    yv_a:units = "degrees" ;
    double xv_a(n_a, nv_a) ;
    xv_a:units = "degrees" ;
    double yv_b(n_b, nv_b) ;
    yv_b:units = "radians" ;
    double xv_b(n_b, nv_b) ;
    xv_b:units = "radians" ;
    int mask_a(n_a) ;
    mask_a:units = "unitless" ;
    int mask_b(n_b) ;
    mask_b:units = "unitless" ;
    double area_a(n_a) ;
    area_a:units = "square radians" ;
    double area_b(n_b) ;
    area_b:units = "square radians" ;
    double frac_a(n_a) ;
    frac_a:units = "unitless" ;
    double frac_b(n_b) ;
    frac_b:units = "unitless" ;
    int col(n_s) ;
    int row(n_s) ;
    double S(n_s) ;
}
```
Variables ended with "_a" are the variables for the source grid and the ones ended with "_b" are the variables for the destination grid. For instance, xc_a and yc_a are corresponding to the grid_center_lon and grid_center_lat variables in the source grid file. The grid information includes the center and corner coordinates and the grid mask arrays (mask_a and mask_b) from the input grid files. The grid areas (area_a and area_b) are either provided by the user or computed by ESMF_RegridWeightGen. The grid area array is only output when the conservative remapping option is used. The values of the area array are set to zero for bilinear and patch remappings. The grid frac arrays (frac_a and frac_b) are calculated by ESMF_RegridWeightGen. For conservative remapping, the grid frac array returns the area fraction of the grid cell which participates in the remapping. For bilinear and patch remapping, the destination grid frac array is one where the grid point participates in the remapping and zero otherwise. For bilinear and patch remapping, the source grid frac array is always set to zero.

The indices and weights generated by ESMF_FieldRegridStore() are stored in the output file as variables col, row and S. Where col and row are the indices to the source and the destination grid cells. These are a one-dimensional array with length defined by dimension n_s. S is the weight which is multiplied by the source value indicated by col and then summed with the destination value indicated by row to build the final interpolated value of the destination.

The global attributes in the interpolation weight file describe some information about the process which generated the weights. The title is always fixed at "ESMF Offline Regridding Weight Generator" for a weight file generated by the ESMF offline weight generation application. The normalization attribute describes how the conservative weights are calculated, currently this is always set to "destarea" because this is the only option which we currently support. The setting "destarea" means that the conservative weights are calculated by dividing the area of the intersection of the source and destination cells by the area of the destination cell. This is set even when the weights are not conservative in which case it can be ignored. The map_method attribute indicates the interpolation type. The format of the interpolation weight file was developed by a group outside of ESMF, because of its use by utilities outside of ESMF control, the range of some of the meta data is constrained. The map_method is one of these. Because of this constraint, there is no map method corresponding to patch interpolation. A weight file generated with the "patch" interpolation method will have map_method set to "Bilinear remapping". The conventions attribute indicates the format of the weight file, currently only "NCAR-CSM" is supported. The attributes domain_a and grid_file_src both indicate the source grid file name. The attributes domain_b and grid_file_dst both indicate the destination grid file name. CVS_revision indicates the version of ESMF containing the application which was used to generate the weight file.

The following code shows how to apply the weights in the weight file to interpolate a source field (src_field) defined over the source grid to a destination field (dst_field) defined over the destination grid. The variables n_s, n_b, row, col, and S are from the weight file.

```fortran
! Initialize destination field to 0.0
do i=1, n_b
  dst_field(i)=0.0
end do
```
enddo

! Apply weights
do i=1, n_s
    dst_field(row(i))=dst_field(row(i))+S(i)*src_field(col(i))
enddo

If the first-order conservative interpolation method was specified ("-m conserve") then the destination field may need to be adjusted by the destination fraction (frac_b) if the destination grid extends outside the unmasked source grid. (If it isn’t known if the destination extends outside the source, then it doesn’t hurt to apply the destination fraction in either case. If it doesn’t extend outside, then the fraction will be 1.0 everywhere anyway.) The following code shows how to adjust an already interpolated destination field (dst_field) by the destination fraction. The variables n_b, and frac_b are from the weight file:

! Adjust destination field by fraction
do i=1, n_b
    if (frac_b(i) .ne. 0.0) then
        dst_field(i)=dst_field(i)/frac_b(i)
    endif
enddo

12.9 ESMF_RegridWeightGenCheck

The ESMF_RegridWeightGen application is used in the ESMF_RegridWeightGenCheck external demo to generate interpolation weights. These weights are then tested by using them for a regridding operation and then comparing them against an analytic function on the destination grid. This external demo is also used to regression test ESMF regridding, and it is run nightly on over 90 combinations of structured and unstructured, regional and global grids, and regridding methods.

13 ESMF_Scrip2Unstruct

13.1 Description

The ESMF_Scrip2Unstruct application is a parallel program that converts a SCRIP format grid file into an unstructured grid file in the ESMF Unstructured file format or in the UGRID file format. This application does not use ESMF library. It uses MPI for communication. This application program can be used together with ESMF_RegridWeightGen application for the unstructured SCRIP format grid files. An unstructured SCRIP grid file will be converted into the ESMF unstructured file format internally in ESMF_RegridWeightGen. The conversion subroutine used in ESMF_RegridWeightGen is sequential and could be slow if the grid file is very big. It will be more efficient to run the ESMF_Scrip2Unstruct first and then regrid the output ESMF or UGRID file using ESMF_RegridWeightGen. Note that a logically rectangular grid file in the SCRIP format (i.e. the dimension grid_rank is equal to 2) can also be converted into an unstructured grid file with this application.

The application usage is as follows:

```bash
ESMF_Scrip2Unstruct inputfile outputfile dualflag [fileformat]
```
where

inputfile - a SCRIP format grid file

outputfile - the output file name

dualflag - 0 for straight conversion and 1 for dual mesh. A dual mesh is a mesh constructed by putting the corner coordinates in the center of the elements and using coordinates to form the mesh corner vertices.

fileformat - an optional argument for the output file format. It could be either ESMF. If not specified, the output file is in the ESMF format.
Part III

Superstructure
14 Overview of Superstructure

ESMF superstructure classes define an architecture for assembling Earth system applications from modeling components. A component may be defined in terms of the physical domain that it represents, such as an atmosphere or sea ice model. It may also be defined in terms of a computational function, such as a data assimilation system. Earth system research often requires that such components be coupled together to create an application. By coupling we mean the data transformations and, on parallel computing systems, data transfers, that are necessary to allow data from one component to be utilized by another. ESMF offers regridding methods and other tools to simplify the organization and execution of inter-component data exchanges.

In addition to components defined at the level of major physical domains and computational functions, components may be defined that represent smaller computational functions within larger components, such as the transformation of data between the physics and dynamics in a spectral atmosphere model, or the creation of nested higher resolution regions within a coarser grid. The objective is to couple components at varying scales both flexibly and efficiently. ESMF encourages a hierarchical application structure, in which large components branch into smaller sub-components (see Figure 2). ESMF also makes it easier for the same component to be used in multiple contexts without changes to its source code.

Key Features
Modular, component-based architecture.
Hierarchical assembly of components into applications.
Use of components in multiple contexts without modification.
Sequential or concurrent component execution.
Single program, multiple datastream (SPMD) applications for maximum portability and reconfigurability.
Multiple program, multiple datastream (MPMD) option for flexibility.

14.1 Superstructure Classes

There are a small number of classes in the ESMF superstructure:

- **Component** An ESMF component has two parts, one that is supplied by ESMF and one that is supplied by the user. The part that is supplied by the framework is an ESMF derived type that is either a Gridded Component (GridComp) or a Coupler Component (CplComp). A Gridded Component typically represents a physical domain in which data is associated with one or more grids - for example, a sea ice model. A Coupler Component arranges and executes data transformations and transfers between one or more Gridded Components. Gridded Components and Coupler Components have standard methods, which include initialize, run, and finalize. These methods can be multi-phase.

  The second part of an ESMF Component is user code, such as a model or data assimilation system. Users set entry points within their code so that it is callable by the framework. In practice, setting entry points means that within user code there are calls to ESMF methods that associate the name of a Fortran subroutine with a corresponding standard ESMF operation. For example, a user-written initialization routine called myOceanInit might be associated with the standard initialize routine of an ESMF Gridded Component named “myOcean” that represents an ocean model.

- **State** ESMF Components exchange information with other Components only through States. A State is an ESMF derived type that can contain Fields, FieldBundles, Arrays, ArrayBundles, and other States. A Component is associated with two States, an **Import State** and an **Export State**. Its Import State holds the data that it receives from other Components. Its Export State contains data that it makes available to other Components.
Figure 2: ESMF enables applications such as the atmospheric general circulation model GEOS-5 to be structured hierarchically, and reconfigured and extended easily. Each box in this diagram is an ESMF Gridded Component.

An ESMF coupled application typically involves a parent Gridded Component, two or more child Gridded Components and one or more Coupler Components.

The parent Gridded Component is responsible for creating the child Gridded Components that are exchanging data, for creating the Coupler, for creating the necessary Import and Export States, and for setting up the desired sequencing. The application’s “main” routine calls the parent Gridded Component’s initialize, run, and finalize methods in order to execute the application. For each of these standard methods, the parent Gridded Component in turn calls the corresponding methods in the child Gridded Components and the Coupler Component. For example, consider a simple coupled ocean/atmosphere simulation. When the initialize method of the parent Gridded Component is called by the application, it in turn calls the initialize methods of its child atmosphere and ocean Gridded Components, and the initialize method of an ocean-to-atmosphere Coupler Component. Figure 3 shows this schematically.

14.2 Hierarchical Creation of Components

Components are allocated computational resources in the form of Persistent Execution Threads, or PETs. A list of a Component’s PETs is contained in a structure called a Virtual Machine, or VM. The VM also contains information about the topology and characteristics of the underlying computer. Components are created hierarchically, with parent Components creating child Components and allocating some or all of their PETs to each one. By default ESMF creates a new VM for each child Component, which allows Components to tailor their VM resources to match their needs. In some cases a child may want to share its parent’s VM - ESMF supports this too.
A Gridded Component may exist across all the PETs in an application. A Gridded Component may also reside on a subset of PETs in an application. These PETs may wholly coincide with, be wholly contained within, or wholly contain another Component.

### 14.3 Sequential and Concurrent Execution of Components

When a set of Gridded Components and a Coupler runs in sequence on the same set of PETs the application is executing in a **sequential** mode. When Gridded Components are created and run on mutually exclusive sets of PETs, and are coupled by a Coupler Component that extends over the union of these sets, the mode of execution is **concurrent**.

Figure 4 illustrates a typical configuration for a simple coupled sequential application, and Figure 5 shows a possible configuration for the same application running in a concurrent mode.

Parent Components can select if and when to wait for concurrently executing child Components, synchronizing only when required.
It is possible for ESMF applications to contain some Component sets that are executing sequentially and others that are executing concurrently. We might have, for example, atmosphere and land Components created on the same subset of PETs, ocean and sea ice Components created on the remainder of PETs, and a Coupler created across all the PETs in the application.

14.4 Intra-Component Communication

All data transfers within an ESMF application occur within a component. For example, a Gridded Component may contain halo updates. Another example is that a Coupler Component may redistribute data between two Gridded Components. As a result, the architecture of ESMF does not depend on any particular data communication mechanism, and new communication schemes can be introduced without affecting the overall structure of the application.

Since all data communication happens within a component, a Coupler Component must be created on the union of the PETs of all the Gridded Components that it couples.

14.5 Data Distribution and Scoping in Components

The scope of distributed objects is the VM of the currently executing Component. For this reason, all PETs in the current VM must make the same distributed object creation calls. When a Coupler Component running on a super-set of a Gridded Component’s PETs needs to make communication calls involving objects created by the Gridded Component, an ESMF-supplied function called ESMF_StateReconcile() creates proxy objects for those PETs that had no previous information about the distributed objects. Proxy objects contain no local data but can be used in communication calls (such as regrid or redistribute) to describe the remote source for data being moved to the current PET, or to describe the remote destination for data being moved from the local PET. Figure 6 is a simple schematic that shows the sequence of events in a reconcile call.

14.6 Performance

The ESMF design enables the user to configure ESMF applications so that data is transferred directly from one component to another, without requiring that it be copied or sent to a different data buffer as an interim step. This is likely to be the most efficient way of performing inter-component coupling. However, if desired, an application can also be configured so that data from a source component is sent to a distinct set of Coupler Component PETs for processing before being sent to its destination.

The ability to overlap computation with communication is essential for performance. When running with ESMF the user can initiate data sends during Gridded Component execution, as soon as the data is ready. Computations can then proceed simultaneously with the data transfer.
Figure 4: Schematic of the run method of a coupled application, with an “Atmosphere” and an “Ocean” Gridded Component running sequentially with an “Atm-Ocean Coupler.” The top-level “Hurricane Model” Gridded Component contains the sequencing information and time advancement loop. The application driver, Coupler, and all Gridded Components are distributed over nine PETs.
Figure 5: Schematic of the run method of a coupled application, with an “Atmosphere” and an “Ocean” Gridded Component running concurrently with an “Atm-Ocean Coupler.” The top-level “Hurricane Model” Gridded Component contains the sequencing information and time advancement loop. The application driver, Coupler, and top-level “Hurricane Model” Gridded Component are distributed over nine PETs. The “Atmosphere” Gridded Component is distributed over three PETs and the “Ocean” Gridded Component is distributed over six PETs.
Figure 6: An ESMF_StateReconcile() call creates proxy objects for use in subsequent communication calls. The reconcile call would normally be made during Coupler initialization.
14.7 Object Model

The following is a simplified UML diagram showing the relationships among ESMF superstructure classes. See Appendix A, *A Brief Introduction to UML*, for a translation table that lists the symbols in the diagram and their meaning.

![Object Model Diagram](image)

15 Application Driver and Required ESMF Methods

15.1 Description

Every ESMF application needs a driver code. Typically the driver layer is implemented as the "main" of the application, although this is not strictly an ESMF requirement. For most ESMF applications the task of the application driver will be very generic: Initialize ESMF, create a top level Component and call its Initialize, Run and Finalize methods, before destroying the top level Component again and calling ESMF Finalize.

ESMF provides a number of different application driver templates in the `$ESMF_DIR/src/Superstructure/AppDriver` directory. An appropriate one can be chosen depending on how the application is to be structured:

**Sequential vs. Concurrent Execution** In a sequential execution model every Component executes on all PETs, with each Component completing execution before the next Component begins. This has the appeal of simplicity of data consumption and production: when a Gridded Component starts all required data is available for use, and when a Gridded Component finishes all data produced is ready for consumption by the next Gridded Component. This approach also has the possibility of less data movement if the grid and data decomposition is done such that each processor’s memory contains the data needed by the next Component.

In a concurrent execution model subgroups of PETs run Gridded Components and multiple Gridded Components are active at the same time. Data exchange must be coordinated between Gridded Components so that data deadlock does not occur. This strategy has the advantage of allowing coupling to other Gridded Components at any time during the computational process, including not having to return to the calling level of code before making data available.

**Pairwise vs. Hub and Spoke** Coupler Components are responsible for taking data from one Gridded Component and putting it into the form expected by another Gridded Component. This might include regridding, change of units, averaging, or binning.
Coupler Components can be written for *pairwise* data exchange: the Coupler Component takes data from a single Component and transforms it for use by another single Gridded Component. This simplifies the structure of the Coupler Component code.

Couplers can also be written using a *hub and spoke* model where a single Coupler accepts data from all other Components, can do data merging or splitting, and formats data for all other Components.

Multiple Couplers, using either of the above two models or some mixture of these approaches, are also possible.

**Implementation Language** The ESMF framework currently has Fortran interfaces for all public functions. Some functions also have C interfaces, and the number of these is expected to increase over time.

**Number of Executables** The simplest way to run an application is to run the same executable program on all PETs. Different Components can still be run on mutually exclusive PETs by using branching (e.g., if this is PET 1, 2, or 3, run Component A, if it is PET 4, 5, or 6 run Component B). This is a *SPMD* model, Single Program Multiple Data.

The alternative is to start a different executable program on different PETs. This is a *MPMD* model, Multiple Program Multiple Data. There are complications with many job control systems on multiprocessor machines in getting the different executables started, and getting inter-process communications established. ESMF currently has some support for MPMD: different Components can run as separate executables, but the Coupler that transfers data between the Components must still run on the union of their PETs. This means that the Coupler Component must be linked into all of the executables.

## 15.2 Constants

### 15.2.1 ESMF_END

**DESCRIPTION:**
The `ESMF_End_Flag` determines how an ESMF application is shut down.

The type of this flag is:

```fortran
type(ESMF_End_Flag)
```

The valid values are:

- **ESMF_END_ABORT** Global abort of the ESMF application. There is no guarantee that all PETs will shut down cleanly during an abort. However, all attempts are made to prevent the application from hanging and the LogErr of at least one PET will be completely flushed during the abort. This option should only be used if a condition is detected that prevents normal continuation or termination of the application. Typical conditions that warrant the use of `ESMF_END_ABORT` are those that occur on a per PET basis where other PETs may be blocked in communication calls, unable to reach the normal termination point.

- **ESMF_END_NORMAL** Normal termination of the ESMF application. Wait for all PETs of the global VM to reach `ESMF_Finalize()` before termination. This is the clean way of terminating an application. `MPI_Finalize()` will be called in case of MPI applications.

- **ESMF_END_KEEPMPI** Same as `ESMF_END_NORMAL` but `MPI_Finalize()` will *not* be called. It is the user code’s responsibility to shut down MPI cleanly if necessary.
15.3 Use and Examples

ESMF encourages application organization in which there is a single top-level Gridded Component. This provides a simple, clear sequence of operations at the highest level, and also enables the entire application to be treated as a sub-Component of another, larger application if desired. When a simple application is organized in this fashion the standard AppDriver can probably be used without much modification.

Examples of program organization using the AppDriver can be found in the src/Superstructure/AppDriver directory. A set of subdirectories within the AppDriver directory follows the naming convention:

<seq|concur>_<_pairwise|hub>_<_f|c>driver_<spmd|mpmd>

The example that is currently implemented is seq_pairwise_fdriver_spmd, which has sequential component execution, a pairwise coupler, a main program in Fortran, and all processors launching the same executable. It is also copied automatically into a top-level quick_start directory at compilation time.

The user can copy the AppDriver files into their own local directory. Some of the files can be used unchanged. Others are template files which have the rough outline of the code but need additional application-specific code added in order to perform a meaningful function. The README file in the AppDriver subdirectory or quick_start directory contains instructions about which files to change.

Examples of concurrent component execution can be found in the system tests that are bundled with the ESMF distribution.

EXAMPLE: This is an AppDriver.F90 file for a sequential ESMF application.

The ChangeMe.F90 file that’s included below contains a number of definitions that are used by the AppDriver, such as the name of the application’s main configuration file and the name of the application’s SetServices routine. This file is in the same directory as the AppDriver.F90 file.

#include "ChangeMe.F90"

program ESMF_AppDriver
#define ESMF_METHOD "program ESMF_AppDriver"
#include "ESMF.h"

! ESMF module, defines all ESMF data types and procedures
use ESMF

! Gridded Component registration routines. Defined in "ChangeMe.F90"
use USER_APP_Mod, only : SetServices => USER_APP_SetServices

implicit none
Define local variables

! Components and States
type(ESMF_GridComp) :: compGridded
type(ESMF_State) :: defaultstate

! Configuration information
type(ESMF_Config) :: config

! A common Grid
type(ESMF_Grid) :: grid

! A Clock, a Calendar, and timesteps
type(ESMF_Clock) :: clock
type(ESMF_TimeInterval) :: timeStep
type(ESMF_Time) :: startTime
type(ESMF_Time) :: stopTime

! Variables related to the Grid
integer :: i_max, j_max

! Return codes for error checks
integer :: rc, localrc

Initialize ESMF. Note that an output Log is created by default.

call ESMF_Initialize(defaultCalKind=ESMF_CALKIND_GREGORIAN, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)
call ESMF_LogWrite("ESMF AppDriver start", ESMF_LOGMSG_INFO)

Create and load a configuration file.
The USER_CONFIG_FILE is set to sample.rc in the ChangeMe.F90 file.
The sample.rc file is also included in the directory with the
AppDriver.F90 file.

call ESMF_ConfigCreate(rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)
call ESMF_ConfigLoadFile(config, USER_CONFIG_FILE, rc = localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Get configuration information.
A configuration file like sample.rc might include:
- size and coordinate information needed to create the default Grid.
- the default start time, stop time, and running intervals for the main time loop.

```fortran
call ESMF_ConfigGetAttribute(config, i_max, label='I Counts:', &
    default=10, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_ConfigGetAttribute(config, j_max, label='J Counts:', &
    default=40, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Create the top Gridded Component.

compGridded = ESMF_GridCompCreate(name="ESMF Gridded Component", &
    rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_LogWrite("Component Create finished", ESMF_LOGMSG_INFO)

Register the set services method for the top Gridded Component.

call ESMF_GridCompSetServices(compGridded, userRoutine=SetServices, rc=rc)
if (ESMF_LogFoundError(rc, msg="Registration failed", rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Create and initialize a Clock.

call ESMF_TimeIntervalSet(timeStep, s=2, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_TimeSet(startTime, yy=2004, mm=9, dd=25, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_TimeSet(stopTime, yy=2004, mm=9, dd=26, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
```

73
call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

clock = ESMF_ClockCreate(timeStep, startTime, stopTime=stopTime, &
    name="Application Clock", rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Create and initialize a Grid.

The default lower indices for the Grid are (/1,1/).
The upper indices for the Grid are read in from the sample.rc file, where they are set to (/10,40/). This means a Grid will be
created with 10 grid cells in the x direction and 40 grid cells in the y direction. The Grid section in the Reference Manual shows how to set
coordinates.

grid = ESMF_GridCreateNoPeriDim(maxIndex=(/i_max, j_max/), &
    name="source grid", rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

! Attach the grid to the Component
call ESMF_GridCompSet(compGridded, grid=grid, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Create and initialize a State to use for both import and export.
In a real code, separate import and export States would normally be
created.

defaultstate = ESMF_StateCreate(name="Default State", rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

Call the initialize, run, and finalize methods of the top component.
When the initialize method of the top component is called, it will in
turn call the initialize methods of all its child components, they
will initialize their children, and so on. The same is true of the
run and finalize methods.

call ESMF_GridCompInitialize(compGridded, importState=defaultstate, &
    exportState=defaultstate, clock=clock, rc=localrc)
if (ESMF_LogFoundError(rc, msg="Initialize failed", rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)
call ESMF_GridCompRun(compGridded, importState=defaultstate, &
    exportState=defaultstate, clock=clock, rc=localrc)
if (ESMF_LogFoundError(rc, msg="Run failed", rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_GridCompFinalize(compGridded, importState=defaultstate, &
    exportState=defaultState, clock=clock, rc=localrc)
if (ESMF_LogFoundError(rc, msg="Finalize failed", rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

--------------------------------------------------- -------------------------
Destroy objects.
--------------------------------------------------- -------------------------

call ESMF_ClockDestroy(clock, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_StateDestroy(defaultstate, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

call ESMF_GridCompDestroy(compGridded, rc=localrc)
if (ESMF_LogFoundError(localrc, ESMF_ERR_PASSTHRU, &
    ESMF_CONTEXT, rcToReturn=rc)) &
    call ESMF_Finalize(rc=localrc, endflag=ESMF_END_ABORT)

--------------------------------------------------- -------------------------
Finalize and clean up.
--------------------------------------------------- -------------------------

call ESMF_Finalize()

end program ESMF_AppDriver

15.4 Required ESMF Methods

There are a few methods that every ESMF application must contain. First, ESMF_Initialize() and
ESMF_Finalize() are in complete analogy to MPI_Init() and MPI_Finalize() known from MPI. All
ESMF programs, serial or parallel, must initialize the ESMF system at the beginning, and finalize it at the end of exec-
ution. The behavior of calling any ESMF method before ESMF_Initialize(), or after ESMF_Finalize() is
undefined.

Second, every ESMF Component that is accessed by an ESMF application requires that its set services routine is called
through ESMF_GRID/CompSetServices(). The Component must implement one public entry point, its
set services routine, that can be called through the ESMF_GRID/CompSetServices() library routine.
The Component set services routine is responsible for setting entry points for the standard ESMF Component methods
Initialize, Run, and Finalize.
Finally, the Component library call ESMF_<Grid/Cpl>CompSetVM() can optionally be issued before calling ESMF_<Grid/Cpl>CompSetServices(). Similar to ESMF_<Grid/Cpl>CompSetServices(), the ESMF_<Grid/Cpl>CompSetVM() call requires a public entry point into the Component. It allows the Component to adjust certain aspects of its execution environment, i.e. its own VM, before it is started up.

The following sections discuss the above mentioned aspects in more detail.

15.4.1 ESMF_Initialize - Initialize ESMF

INTERFACE:

    subroutine ESMF_Initialize(defaultConfigFileName, defaultCalKind, &
    defaultLogFileName, logkindflag, mpiCommunicator, &
    ioUnitLBound, ioUnitUBound, vm, rc)

ARGUMENTS:

    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(len= *), intent(in), optional :: defaultConfigFileName
    type(ESMF_CalKind_Flag), intent(in), optional :: defaultCalKind
    character(len= *), intent(in), optional :: defaultLogFileName
    type(ESMF_LogKind_Flag), intent(in), optional :: logkindflag
    integer, intent(in), optional :: mpiCommunicator
    integer, intent(in), optional :: ioUnitLBound
    integer, intent(in), optional :: ioUnitUBound
    type(ESMF_VM), intent(out), optional :: vm
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method must be called once on each PET before any other ESMF methods are used. The method contains a barrier before returning, ensuring that all processes made it successfully through initialization.

Typically ESMF_Initialize() will call MPI_Init() internally unless MPI has been initialized by the user code before initializing the framework. If the MPI initialization is left to ESMF_Initialize() it inherits all of the MPI implementation dependent limitations of what may or may not be done before MPI_Init(). For instance, it is unsafe for some MPI implementations, such as MPICH, to do IO before the MPI environment is initialized. Please consult the documentation of your MPI implementation for details.

Note that when using MPICH as the MPI library, ESMF needs to use the application command line arguments for MPI_Init(). However, ESMF acquires these arguments internally and the user does not need to worry about providing them. Also, note that ESMF does not alter the command line arguments, so that if the user obtains them they will be as specified on the command line (including those which MPICH would normally strip out).
By default, `ESMF_Initialize()` will open multiple error log files, one per processor. This is very useful for debugging purpose. However, when running the application on a large number of processors, opening a large number of log files and writing log messages from all the processors could become a performance bottleneck. Therefore, it is recommended to turn the Error Log feature off in these situations by setting `logkindflag` to `ESMF_LOGKIND_NONE`.

When integrating ESMF with applications where Fortran unit number conflicts exist, the optional `ioUnitLBound` and `ioUnitUBound` arguments may be used to specify an alternate unit number range. See section 49.2.1 for more information on how ESMF uses Fortran unit numbers.

Before exiting the application the user must call `ESMF_Finalize()` to release resources and clean up ESMF gracefully.

The arguments are:

- `[defaultConfigFilename]` Name of the default configuration file for the entire application.
- `[defaultCalKind]` Sets the default calendar to be used by ESMF Time Manager. See section 40.2.1 for a list of valid options. If not specified, defaults to ESMF_CALKIND_NOCALENDAR.
- `[defaultLogFileName]` Name of the default log file for warning and error messages. If not specified, defaults to ESMF_ErrorLog.
- `[logkindflag]` Sets the default Log Type to be used by ESMF Log Manager. See section 46.2.2 for a list of valid options. If not specified, defaults to ESMF_LOGKIND_MULTI.
- `[mpiCommunicator]` MPI communicator defining the group of processes on which the ESMF application is running. If not specified, defaults to MPI_COMM_WORLD.
- `[ioUnitLBound]` Lower bound for Fortran unit numbers used within the ESMF library. Fortran units are primarily used for log files. Legal unit numbers are positive integers. A value higher than 10 is recommended in order to avoid the compiler-specific reservations which are typically found on the first few units. If not specified, defaults to ESMF_LOG_FORT_UNIT_NUMBER, which is distributed with a value of 50.
- `[ioUnitUBound]` Upper bound for Fortran unit numbers used within the ESMF library. Must be set to a value at least 5 units higher than `ioUnitLBound`. If not specified, defaults to ESMF_LOG_UPPER, which is distributed with a value of 99.
- `[vm]` Returns the global ESMF_VM that was created during initialization.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.

### 15.4.2 ESMF_Finalize - Clean up and shut down ESMF

**INTERFACE:**

```fortran
subroutine ESMF_Finalize(endflag, rc)
```

**ARGUMENTS:**

- `endflag` (optional, type `ESMF_End_Flag`, intent(in))
- `rc` (optional, intent(out), integer)

---

77
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This must be called once on each PET before the application exits to allow ESMF to flush buffers, close open connections, and release internal resources cleanly. The optional argument `endflag` may be used to indicate the mode of termination. Note that this call must be issued only once per PET with `endflag=ESMF_END_NORMAL`, and that this call may not be followed by `ESMF_Initialize()`. This last restriction means that it is not possible to restart ESMF within the same execution.

The arguments are:

- **[endflag]** Specify mode of termination. The default is `ESMF_END_NORMAL` which waits for all PETs of the global VM to reach `ESMF_Finalize()` before termination. See section [15.2.1](#) for a complete list and description of valid flags.

- **[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

### 15.4.3 User-code SetServices method

Many programs call some library routines. The library documentation must explain what the routine name is, what arguments are required and what are optional, and what the code does.

In contrast, all ESMF components must be written to be called by another part of the program; in effect, an ESMF component takes the place of a library. The interface is prescribed by the framework, and the component writer must provide specific subroutines which have standard argument lists and perform specific operations. For technical reasons none of the arguments in user-provided subroutines must be declared as optional.

The only required public interface of a Component is its SetServices method. This subroutine must have an externally accessible name (be a public symbol), take a component as the first argument, and an integer return code as the second. Both arguments are required and must not be declared as optional. If an intent is specified in the interface it must be `intent(inout)` for the first and `intent(out)` for the second argument. The subroutine name is not predefined, it is set by the component writer, but must be provided as part of the component documentation.

The required function that the SetServices subroutine must provide is to specify the user-code entry points for the standard ESMF Component methods. To this end the user-written SetServices routine calls the `ESMF_<Grid/Cpl>CompSetEntryPoint()` method to set each Component entry point. See sections [16.2.1](#) and [17.2.1](#) for examples of how to write a user-code SetServices routine.

Note that a component does not call its own SetServices routine; the AppDriver or parent component code, which is creating a component, will first call `ESMF_<Grid/Cpl>CompCreate()` to create a component object, and then must call into `ESMF_<Grid/Cpl>CompSetServices()`, supplying the user-code SetServices routine as an argument. The framework then calls into the user-code SetServices, after the Component’s VM has been started up.

It is good practice to package the user-code implementing a component into a Fortran module, with the user-code SetService routine being the only public module method. ESMF supports three mechanisms for accessing the user-code SetServices routine from the calling AppDriver or parent component.

- **Fortran USE association**: The AppDriver or parent component utilizes the standard Fortran USE statement on the component module to make all public entities available. The user-code SetServices routine can then be
passed directly into the `ESMF_<Grid/Cpl>CompSetServices()` interface documented in [16.4.18](#16.4.18) and [17.4.18](#17.4.18) respectively.

**Pros:** Standard Fortran module use: name mangling and interface checking is handled by the Fortran compiler.  

**Cons:** Fortran 90/95 has no mechanism to implement a "smart" dependency scheme through USE association. Any change in a lower level component module (even just adding or changing a comment!) will trigger a complete recompilation of all of the higher level components throughout the component hierarchy. This situation is particularly annoying for ESMF componentized code, where the prescribed ESMF component interfaces, in principle, remove all interdependencies between components that would require recompilation.

Fortran **submodules**, introduced as an extension to Fortran 2003, and now part of the Fortran 2008 standard, are designed to avoid this "false" dependency issue. A code change to an ESMF component that keeps the actual implementation within a submodule, will not trigger a recompilation of the components further up in the component hierarchy. Unfortunately, as of late 2012, support for submodules is virtually absent across the common Fortran compilers.

- **External routine:** The AppDriver or parent component provides an explicit interface block for an external routine that implements (or calls) the user-code SetServices routine. This routine can then be passed directly into the `ESMF_<Grid/Cpl>CompSetServices()` interface documented in [16.4.18](#16.4.18) and [17.4.18](#17.4.18). (In practice this can be implemented by the component as an external subroutine that simply calls into the user-code SetServices module routine.)

  **Pros:** Avoids Fortran USE dependencies: a change to lower level component code will not trigger a complete recompilation of all of the higher level components throughout the component hierarchy. Name mangeling is handled by the Fortran compiler.  

  **Cons:** The user-code SetServices interface is not checked by the compiler. The user must ensure uniqueness of the external routine name across the entire application.

- **Name lookup:** The AppDriver or parent component specifies the user-code SetServices routine by name. The actual lookup and code association does not occur until runtime. The name string is passed into the `ESMF_<Grid/Cpl>CompSetServices()` interface documented in [16.4.19](#16.4.19) and [17.4.19](#17.4.19).  

  **Pros:** Avoids Fortran USE dependencies: a change to lower level component code will not trigger a complete recompilation of all of the higher level components throughout the component hierarchy. The component code does not have to be accessible until runtime and may be located in a shared object, thus avoiding relinking of the application.  

  **Cons:** The user-code SetServices interface is not checked by the compiler. The user must explicitly deal with all of the Fortran name mangling issues: 1) Accessing a module routine requires precise knowledge of the name mangeling rules of the specific compiler. Alternatively the user-code SetServices routine may be implemented as an external routine, avoiding the module name mangeling. 2) Even then, Fortran compilers typically append one or two underscores on a symbol name. This must be considered when passing the name into the `ESMF_<Grid/Cpl>CompSetServices()` method.

### 15.4.4 User-code Initialize, Run, and Finalize methods

The required standard ESMF Component methods, for which user-code entry points must be set, are Initialize, Run, and Finalize. Currently optional, a Component may also set entry points for the WriteRestart and ReadRestart methods. Sections [16.2.1](#16.2.1) and [17.2.1](#17.2.1) provide examples of how the entry points for Initialize, Run, and Finalize are set during the user-code SetServices routine, using the `ESMF_<Grid/Cpl>CompSetEntryPoint()` library call.

All standard user-code methods must abide exactly to the prescribed interfaces. None of the arguments must be declared as *optional*. 

79
The names of the Initialize, Run, and Finalize user-code subroutines do not need to be public; in fact it is far better for them to be private to lower the chances of public symbol clashes between different components.

See sections 16.2.2, 16.2.3, 16.2.4, and 17.2.2, 17.2.3, 17.2.4 for examples of how to write entry points for the standard ESMF Component methods.

15.4.5 User-code SetVM method

When the AppDriver or parent component code calls ESMF_<Grid/Cpl>CompCreate() it has the option to specify a petList argument. All of the parent PETs contained in this list become resources of the child component. By default, without the petList argument, all of the parent PETs are provided to the child component.

Typically each component has its own virtual machine (VM) object. However, using the optional contextflag argument during ESMF_<Grid/Cpl>CompCreate() a child component can inherit its parent component’s VM. Unless a child component inherits the parent VM, it has the option to set certain aspects of how its VM utilizes the provided resources. The resources provided via the parent PETs are the associated processing elements (PEs) and virtual address spaces (VASs).

The optional user-written SetVM routine is called from the parent for the child through the ESMF_<Grid/Cpl>CompSetVM() method. This is the only place where the child component can set aspects of its own VM before it is started up. The child component’s VM must be running before the SetServices routine can be called, and thus the parent must call the optional ESMF_<Grid/Cpl>CompSetVM() method before ESMF_<Grid/Cpl>CompSetServices().

Inside the user-code called by the SetVM routine, the component has the option to specify how the PETs share the provided parent PEs. Further, PETs on the same single system image (SSI) can be set to run multi-threaded within a reduced number of virtual address spaces (VAS), allowing a component to leverage shared memory concepts.

Sections 16.2.5 and 17.2.5 provide examples for simple user-written SetVM routines.

16 GridComp Class

16.1 Description

In Earth system modeling, the most natural way to think about an ESMF Gridded Component, or ESMF_GridComp, is as a piece of code representing a particular physical domain, such as an atmospheric model or an ocean model. Gridded Components may also represent individual processes, such as radiation or chemistry. It’s up to the application writer to decide how deeply to “componentize.”

Earth system software components tend to share a number of basic features. Most ingest and produce a variety of physical fields, refer to a (possibly noncontiguous) spatial region and a grid that is partitioned across a set of computational resources, and require a clock for things like stepping a governing set of PDEs forward in time. Most can also be divided into distinct initialize, run, and finalize computational phases. These common characteristics are used within ESMF to define a Gridded Component data structure that is tailored for Earth system modeling and yet is still flexible enough to represent a variety of domains.

A well designed Gridded Component does not store information internally about how it couples to other Gridded Components. That allows it to be used in different contexts without changes to source code. The idea here is to avoid situations in which slightly different versions of the same model source are maintained for use in different contexts - standalone vs. coupled versions, for example. Data is passed in and out of Gridded Components using an ESMF State, this is described in Section 20.1.
An ESMF Gridded Component has two parts, one which is user-written and another which is part of the framework. The user-written part is software that represents a physical domain or performs some other computational function. It forms the body of the Gridded Component. It may be a piece of legacy code, or it may be developed expressly for use with ESMF. It must contain routines with standard ESMF interfaces that can be called to initialize, run, and finalize the Gridded Component. These routines can have separate callable phases, such as distinct first and second initialization steps.

ESMF provides the Gridded Component derived type, ESMF_GridComp. An ESMF_GridComp must be created for every portion of the application that will be represented as a separate component. For example, in a climate model, there may be Gridded Components representing the land, ocean, sea ice, and atmosphere. If the application contains an ensemble of identical Gridded Components, every one has its own associated ESMF_GridComp. Each Gridded Component has its own name and is allocated a set of computational resources, in the form of an ESMF Virtual Machine, or VM.

The user-written part of a Gridded Component is associated with an ESMF_GridComp derived type through a routine called ESMF_SetServices(). This is a routine that the user must write, and declare public. Inside the SetServices routine the user must call ESMF_SetEntryPoint() methods that associate a standard ESMF operation with the name of the corresponding Fortran subroutine in their user code.

### 16.2 Use and Examples

A Gridded Component is a computational entity which consumes and produces data. It uses a State object to exchange data between itself and other Components. It uses a Clock object to manage time, and a VM to describe its own and its child components’ computational resources.

This section shows how to create Gridded Components. For demonstrations of the use of Gridded Components, see the system tests that are bundled with the ESMF software distribution. These can be found in the directory esmf/src/system_tests.

#### 16.2.1 Implement a user-code SetServices routine

Every ESMF_GridComp is required to provide and document a public set services routine. It can have any name, but must follow the declaration below: a subroutine which takes an ESMF_GridComp as the first argument, and an integer return code as the second. Both arguments are required and must not be declared as optional. If an intent is specified in the interface it must be intent(inout) for the first and intent(out) for the second argument.

The set services routine must call the ESMF method ESMF_GridCompSetEntryPoint() to register with the framework what user-code subroutines should be called to initialize, run, and finalize the component. There are additional routines which can be registered as well, for checkpoint and restart functions.

Note that the actual subroutines being registered do not have to be public to this module; only the set services routine itself must be available to be used by other code.

```fortran
module ESMF_GriddedCompEx
  public GComp_SetServices
  public GComp_SetVM
contains
```

! Example Gridded Component
module ESMF_GriddedCompEx
  use ESMF
  implicit none
  public GComp_SetServices
  public GComp_SetVM
```
subroutine GComp_SetServices(comp, rc)
    type(ESMF_GridComp) :: comp ! must not be optional
    integer, intent(out) :: rc ! must not be optional

    ! Set the entry points for standard ESMF Component methods
    call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_INITIALIZE, &
        userRoutine=GComp_Init, rc=rc)
    call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_RUN, &
        userRoutine=GComp_Run, rc=rc)
    call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_FINALIZE, &
        userRoutine=GComp_Final, rc=rc)

    rc = ESMF_SUCCESS
end subroutine

16.2.2 Implement a user-code Initialize routine

When a higher level component is ready to begin using an ESMF_GridComp, it will call its initialize routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

At initialization time the component can allocate data space, open data files, set up initial conditions; anything it needs to do to prepare to run.

The rc return code should be set if an error occurs, otherwise the value ESMF_SUCCESS should be returned.

subroutine GComp_Init(comp, importState, exportState, clock, rc)
    type(ESMF_GridComp) :: comp ! must not be optional
    type(ESMF_State) :: importState ! must not be optional
    type(ESMF_State) :: exportState ! must not be optional
    type(ESMF_Clock) :: clock ! must not be optional
    integer, intent(out) :: rc ! must not be optional

    print *, "Gridded Comp Init starting"

    ! This is where the model specific setup code goes.

    ! If the initial Export state needs to be filled, do it here.
    !call ESMF_StateAdd(exportState, field, rc)
    !call ESMF_StateAdd(exportState, bundle, rc)
    print *, "Gridded Comp Init returning"

    rc = ESMF_SUCCESS
end subroutine GComp_Init
16.2.3 Implement a user-code Run routine

During the execution loop, the run routine may be called many times. Each time it should read data from the importState, use the clock to determine what the current time is in the calling component, compute new values or process the data, and produce any output and place it in the exportState.

When a higher level component is ready to use the ESMF_GridComp it will call its run routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

It is expected that this is where the bulk of the model computation or data analysis will occur.

The rc return code should be set if an error occurs, otherwise the value ESMF_SUCCESS should be returned.

```fortran
subroutine GComp_Run(comp, importState, exportState, clock, rc)
  type(ESMF_GridComp) :: comp ! must not be optional
  type(ESMF_State) :: importState ! must not be optional
  type(ESMF_State) :: exportState ! must not be optional
  type(ESMF_Clock) :: clock ! must not be optional
  integer, intent(out) :: rc ! must not be optional

  print *, "Gridded Comp Run starting"
  ! call ESMF_StateGet(), etc to get fields, bundles, arrays
  ! from import state.

  ! This is where the model specific computation goes.

  ! Fill export state here using ESMF_StateAdd(), etc

  print *, "Gridded Comp Run returning"
  rc = ESMF_SUCCESS
end subroutine GComp_Run
```

16.2.4 Implement a user-code Finalize routine

At the end of application execution, each ESMF_GridComp should deallocate data space, close open files, and flush final results. These functions should be placed in a finalize routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

The rc return code should be set if an error occurs, otherwise the value ESMF_SUCCESS should be returned.

```fortran
subroutine GComp_Final(comp, importState, exportState, clock, rc)
  type(ESMF_GridComp) :: comp ! must not be optional
  type(ESMF_State) :: importState ! must not be optional
  type(ESMF_State) :: exportState ! must not be optional
  type(ESMF_Clock) :: clock ! must not be optional
  integer, intent(out) :: rc ! must not be optional
```

83
print *, "Gridded Comp Final starting"
! Add whatever code here needed
print *, "Gridded Comp Final returning"
rc = ESMF_SUCCESS
end subroutine GComp_Final

16.2.5 Implement a user-code SetVM routine

Every ESMF_GridComp can optionally provide and document a public set vm routine. It can have any name, but must follow the declaration below: a subroutine which takes an ESMF_GridComp as the first argument, and an integer return code as the second. Both arguments are required and must not be declared as optional. If an intent is specified in the interface it must be intent (inout) for the first and intent (out) for the second argument.

The set vm routine is the only place where the child component can use the ESMF_GridCompSetVMMaxPEs(), or ESMF_GridCompSetVMMaxThreads(), or ESMF_GridCompSetVMMinThreads() call to modify aspects of its own VM.

A component’s VM is started up right before its set services routine is entered. ESMF_GridCompSetVM() is executing in the parent VM, and must be called before ESMF_GridCompSetServices().

subroutine GComp_SetVM(comp, rc)
type(ESMF_GridComp) :: comp ! must not be optional
integer, intent(out) :: rc ! must not be optional
type(ESMF_VM) :: vm
logical :: pthreadsEnabled
! Test for Pthread support, all SetVM calls require it
call ESMF_VMGetGlobal(vm, rc=rc)
call ESMF_VMGet(vm, pthreadsEnabledFlag=pthreadsEnabled, rc=rc)
if (pthreadsEnabled) then
  ! run PETs single-threaded
  call ESMF_GridCompSetVMMinThreads(comp, rc=rc)
endif
rc = ESMF_SUCCESS
end subroutine
end module ESMF_GriddedCompEx
16.2.6 Set and Get the Internal State

ESMF provides the concept of an Internal State that is associated with a Component. Through the Internal State API a user can attach a private data block to a Component, and later retrieve a pointer to this memory allocation. Setting and getting of Internal State information are supported from anywhere in the Component’s SetServices, Initialize, Run, or Finalize code.

The code below demonstrates the basic Internal State API of `ESMF_<Grid|Cpl>SetInternalState()` and `ESMF_<Grid|Cpl>GetInternalState()`. Notice that an extra level of indirection to the user data is necessary!

```fortran
! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

type(ESMF_GridComp) :: comp
integer :: rc, finalrc

! Internal State Variables

type testData
  sequence
    integer :: testValue
    real :: testScaling
  end type

type dataWrapper
  sequence
    type(testData), pointer :: p
  end type

type(dataWrapper) :: wrap1, wrap2

type(testData), target :: data

type(testData), pointer :: datap ! extra level of indirection

!----------------------------------------------------------
call ESMF_Initialize(defaultlogfilename="InternalStateEx.Log", &
  logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!----------------------------------------------------------

! Creation of a Component
comp = ESMF_GridCompCreate(name="test", rc=rc)
if (rc .ne. ESMF_SUCCESS) finalrc = ESMF_FAILURE
!----------------------------------------------------------
! This could be called, for example, during a Component’s initialize phase.

! Initialize private data block
data%testValue = 4567
data%testScaling = 0.5
```

85
! Set Internal State
wrap1%p => data
call ESMF_GridCompSetInternalState(comp, wrap1, rc)
if (rc .ne. ESMF_SUCCESS) finalrc = ESMF_FAILURE

! This could be called, for example, during a Component’s run phase.

! Get Internal State
call ESMF_GridCompGetInternalState(comp, wrap2, rc)
if (rc .ne. ESMF_SUCCESS) finalrc = ESMF_FAILURE

! Access private data block and verify data
datap => wrap2%p
if ((datap%testValue .ne. 4567) .or. (datap%testScaling .ne. 0.5)) then
    print *, "did not get same values back"
    finalrc = ESMF_FAILURE
else
    print *, "got same values back from GetInternalState as original"
endif

When working with ESMF Internal States it is important to consider the applying scoping rules. The user must ensure that the private data block, that is being referenced, persists for the entire access period. This is not an issue in the previous example, where the private data block was defined on the scope of the main program. However, the Internal State construct is often useful inside of Component modules to hold Component specific data between calls. One option to ensure persisting private data blocks is to use the Fortran SAVE attribute either on local or module variables. A second option, illustrated in the following example, is to use Fortran pointers and user controlled memory management via allocate() and deallocate() calls.

One situation where the Internal State is useful is in the creation of ensembles of the same Component. In this case it can be tricky to distinguish which data, held in saved module variables, belongs to which ensemble member - especially if the ensemble members are executing on the same set of PETs. The Internal State solves this problem by providing a handle to instance specific data allocations.

module user_mod
    use ESMF
    implicit none
    ! module variables
    private
    ! Internal State Variables
type testData
        sequence
            integer :: testValue ! scalar data
            real :: testScaling ! scalar data
            real, pointer :: testArray(:) ! array data
        end type

type dataWrapper
sequence
    type(testData), pointer :: p
end type

contains !------------------------------------------ --------------------

subroutine mygcomp_init(gcomp, istate, estate, clock, rc)
    type(ESMF_GridComp):: gcomp
    type(ESMF_State):: istate, estate
    type(ESMF_Clock):: clock
    integer, intent(out):: rc

    ! Local variables
    type(dataWrapper) :: wrap
    type(testData), pointer :: data
    integer :: i

    rc = ESMF_SUCCESS

    ! Allocate private data block
    allocate(data)

    ! Initialize private data block
    data%testValue = 4567 ! initialize scalar data
    data%testScaling = 0.5 ! initialize scalar data
    allocate(data%testArray(10)) ! allocate array data

    do i = 1, 10
        data%testArray(i) = real(i) ! initialize array data
    enddo

    ! In a real ensemble application the initial data would be set to
    ! something unique for this ensemble member. This could be
    ! accomplished for example by reading a member specific config file
    ! that was specified by the driver code. Alternatively, Attributes,
    ! set by the driver, could be used to label the Component instances
    ! as specific ensemble members.

    ! Set Internal State
    wrap%p => data
    call ESMF_GridCompSetInternalState(gcomp, wrap, rc)

end subroutine !------------------------------------- ------------------

subroutine mygcomp_run(gcomp, istate, estate, clock, rc)
    type(ESMF_GridComp):: gcomp
    type(ESMF_State):: istate, estate
    type(ESMF_Clock):: clock
    integer, intent(out):: rc

    ! Local variables
type(dataWrapper) :: wrap
type(testData), pointer :: data
logical :: match = .true.
integer :: i

rc = ESMF_SUCCESS

! Get Internal State
call ESMF_GridCompGetInternalState(gcomp, wrap, rc)
if (rc/=ESMF_SUCCESS) return

! Access private data block and verify data
data => wrap%p
if (data%testValue .ne. 4567) match = .false. ! test scalar data
if (data%testScaling .ne. 0.5) match = .false. ! test scalar data
do i=1, 10
   if (data%testArray(i) .ne. real(i)) match = .false. ! test array data
enddo
if (match) then
   print *, "got same values back from GetInternalState as original"
else
   print *, "did not get same values back"
   rc = ESMF_FAILURE
endif

end subroutine !------------------------------------- ------------------

subroutine mygcomp_final(gcomp, istate, estate, clock, rc)
type(ESMF_GridComp):: gcomp
type(ESMF_State):: istate, estate
type(ESMF_Clock):: clock
integer, intent(out):: rc

! Local variables
type(dataWrapper) :: wrap
type(testData), pointer :: data

rc = ESMF_SUCCESS

! Get Internal State
call ESMF_GridCompGetInternalState(gcomp, wrap, rc)
if (rc/=ESMF_SUCCESS) return

! Deallocate private data block
data => wrap%p
deallocate(data%testArray) ! deallocate array data
deallocate(data)

end subroutine !------------------------------------- -------------------------

end module
16.3 Restrictions and Future Work

1. **No optional arguments.** User-written routines called by SetServices, and registered for Initialize, Run and Finalize, *must not* declare any of the arguments as optional.

2. **Namespace isolation.** If possible, Gridded Components should attempt to make all data private, so public names do not interfere with data in other components.

3. **Single execution mode.** It is not expected that a single Gridded Component be able to function in both sequential and concurrent modes, although Gridded Components of different types can be nested. For example, a concurrently called Gridded Component can contain several nested sequential Gridded Components.

16.4 Class API

16.4.1 ESMF_GridCompAssignment(=) - GridComp assignment

**INTERFACE:**

```interface assignment(=)
gridcomp1 = gridcomp2```

**ARGUMENTS:**

```type(ESMF_GridComp) :: gridcomp1
type(ESMF_GridComp) :: gridcomp2```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Assign gridcomp1 as an alias to the same ESMF GridComp object in memory as gridcomp2. If gridcomp2 is invalid, then gridcomp1 will be equally invalid after the assignment.

The arguments are:

- `gridcomp1` The ESMF_GridComp object on the left hand side of the assignment.
- `gridcomp2` The ESMF_GridComp object on the right hand side of the assignment.

16.4.2 ESMF_GridCompOperator(==) - GridComp equality operator

**INTERFACE:**

```
interface operator(==)
  if (gridcomp1 == gridcomp2) then ... endif
  OR
  result = (gridcomp1 == gridcomp2)
end interface

RETURN VALUE:

  logical :: result

ARGUMENTS:

  type(ESMF_GridComp), intent(in) :: gridcomp1
  type(ESMF_GridComp), intent(in) :: gridcomp2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether gridcomp1 and gridcomp2 are valid aliases to the same ESMF GridComp object in memory. For a more general comparison of two ESMF GridComps, going beyond the simple alias test, the ESMF_GridCompMatch() function (not yet implemented) must be used.

The arguments are:

  gridcomp1  The ESMF/GridComp object on the left hand side of the equality operation.
  gridcomp2  The ESMF/GridComp object on the right hand side of the equality operation.

16.4.3  ESMF_GridCompOperator(/=) - GridComp not equal operator

INTERFACE:

interface operator(/=)
  if (gridcomp1 /= gridcomp2) then ... endif
  OR
  result = (gridcomp1 /= gridcomp2)
end interface

RETURN VALUE:

  logical :: result

ARGUMENTS:

  type(ESMF_GridComp), intent(in) :: gridcomp1
  type(ESMF_GridComp), intent(in) :: gridcomp2
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether gridcomp1 and gridcomp2 are not valid aliases to the same ESMF GridComp object in memory. For a more general comparison of two ESMF GridComps, going beyond the simple alias test, the ESMF_GridCompMatch() function (not yet implemented) must be used.

The arguments are:

gridcomp1 The ESMF_GridComp object on the left hand side of the non-equality operation.
gridcomp2 The ESMF_GridComp object on the right hand side of the non-equality operation.

16.4.4  ESMF_GridCompCreate - Create a GridComp

INTERFACE:

recursive function ESMF_GridCompCreate(grid, &
    config, configFile, clock, petList, contextflag, name, rc)

RETURN VALUE:

type(ESMF_GridComp) :: ESMF_GridCompCreate

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Grid),    intent(in), optional :: grid
type(ESMF_Config),   intent(in), optional :: config
character(len=*),   intent(in), optional :: configFile
type(ESMF_Clock),    intent(in), optional :: clock
integer,            intent(in), optional :: petList(:)
type(ESMF_Context_Flag), intent(in), optional :: contextflag
character(len=*),   intent(in), optional :: name
integer,            intent(out),  optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:
This interface creates an ESMF_GridComp object. By default, a separate VM context will be created for each component. This implies creating a new MPI communicator and allocating additional memory to manage the VM resources. When running on a large number of processors, creating a separate VM for each component could be both time and memory inefficient. If the application is sequential, i.e., each component is running on all the PETs of the global VM, it will be more efficient to use the global VM instead of creating a new one. This can be done by setting contextflag to ESMF_CONTEXT_PARENT_VM.

The return value is the new ESMF_GridComp.

The arguments are:

[grid] Default ESMF_Grid associated with this gridcomp. Note that it is perfectly ok to not pass a Grid in for this argument. This argument is simply a convenience for the user to allow them to associate a Grid with a component for their later use. The grid isn’t actually used in the component code.

[config] An already-created ESMF_Config configuration object from which the new component can read in namelist-type information to set parameters for this run. If both are specified, this object takes priority over configFile.

[configFile] The filename of an ESMF_Config format file. If specified, this file is opened an ESMF_Config configuration object is created for the file, and attached to the new component. The user can call ESMF_GridCompGet() to get and use the object. If both are specified, the config object takes priority over this one.

[clock] Component-specific ESMF_Clock. This clock is available to be queried and updated by the new ESMF_GridComp as it chooses. This should not be the parent component clock, which should be maintained and passed down to the initialize/run/finalize routines separately.

[petList] List of parent PETs given to the created child component by the parent component. If petList is not specified all of the parent PETs will be given to the child component. The order of PETs in petList determines how the child local PETs refer back to the parent PETs.

[contextflag] Specify the component’s VM context. The default context is ESMF_CONTEXT_OWN_VM. See section 50.9 for a complete list of valid flags.

[name] Name of the newly-created ESMF_GridComp. This name can be altered from within the ESMF_GridComp code once the initialization routine is called.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.5 ESMF_GridCompDestroy - Release resources associated with a GridComp

INTERFACE:

recursive subroutine ESMF_GridCompDestroy(gridcomp, &
  timeout, timeoutFlag, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(inout) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: timeout
  logical, intent(out), optional :: timeoutFlag
  integer, intent(out), optional :: rc

92
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0  Added argument `timeout`. Added argument `timeoutFlag`. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Destroys an `ESMF_GridComp`, releasing the resources associated with the object.

The arguments are:

- **gridcomp**  Release all resources associated with this `ESMF_GridComp` and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.
- **[timeout]**  The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The `timeout` argument is only supported for connected dual components.
- **[timeoutFlag]**  Returns `.true.` if the timeout was reached, `.false.` otherwise. If `timeoutFlag` was not provided, a timeout condition will lead to a return code of `rc \= ESMF_SUCCESS`. Otherwise the return value of `timeoutFlag` is the sole indicator of a timeout condition.
- **[rc]**  Return code; equals `ESMF_SUCCESS` if there are no errors.

16.4.6  ESMF_GridCompFinalize - Call the GridComp’s finalize routine

INTERFACE:

```fortran
recursive subroutine ESMF_GridCompFinalize(gridcomp, &
    importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
    userRc, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_GridComp), intent(inout) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_State), intent(inout), optional :: importState
  type(ESMF_State), intent(inout), optional :: exportState
  type(ESMF_Clock), intent(inout), optional :: clock
  type(ESMF_Sync_Flag), intent(in), optional :: syncflag
  integer, intent(in), optional :: phase
  integer, intent(in), optional :: timeout
```
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user-supplied finalization routine for an ESMF_GridComp.

The arguments are:

gridcomp The ESMF_GridComp to call finalize routine for.

[importState] ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase] Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multi-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached. .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc != ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.7 ESMF_GridCompGet - Get GridComp information

INTERFACE:

subroutine ESMF_GridCompGet(gridcomp, gridIsPresent, grid, &
  importStateIsPresent, importState, exportStateIsPresent, exportState, &
  configIsPresent, config, configFileIsPresent, configFile, &
  clockIsPresent, clock, localPet, petCount, contextflag, &
  currentMethod, currentPhase, comptype, vmIsPresent, vm, name, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(in) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical, intent(out), optional :: gridIsPresent
  type(ESMF_Grid), intent(out), optional :: grid
  logical, intent(out), optional :: importStateIsPresent
  type(ESMF_State), intent(out), optional :: importState
  logical, intent(out), optional :: exportStateIsPresent
  type(ESMF_State), intent(out), optional :: exportState
  logical, intent(out), optional :: configIsPresent
  type(ESMF_Config), intent(out), optional :: config
  logical, intent(out), optional :: configFileIsPresent
  character(len=*) , intent(out), optional :: configFile
  logical, intent(out), optional :: clockIsPresent
  type(ESMF_Clock), intent(out), optional :: clock
  integer, intent(out), optional :: localPet
  integer, intent(out), optional :: petCount
  type(ESMF_Context_Flag), intent(out), optional :: contextflag
  type(ESMF_Method_Flag), intent(out), optional :: currentMethod
  integer, intent(out), optional :: currentPhase
  type(ESMF_CompType_Flag), intent(out), optional :: comptype
  logical, intent(out), optional :: vmIsPresent
  type(ESMF_VM), intent(out), optional :: vm
  character(len=*) , intent(out), optional :: name
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get information about an ESMF_GridComp object.

The arguments are:
gridcomp  The ESMF_GridComp object being queried.

[gridIsPresent] .true. if grid was set in GridComp object, .false. otherwise.

[grid] Return the associated Grid. It is an error to query for the Grid if none is associated with the GridComp. If unsure, get gridIsPresent first to determine the status.

[importStateIsPresent] .true. if importState was set in GridComp object, .false. otherwise.

[importState] Return the associated import State. It is an error to query for the import State if none is associated with the GridComp. If unsure, get importStateIsPresent first to determine the status.

[exportStateIsPresent] .true. if exportState was set in GridComp object, .false. otherwise.

[exportState] Return the associated export State. It is an error to query for the export State if none is associated with the GridComp. If unsure, get exportStateIsPresent first to determine the status.

[configIsPresent] .true. if config was set in GridComp object, .false. otherwise.

[config] Return the associated Config. It is an error to query for the Config if none is associated with the GridComp. If unsure, get configIsPresent first to determine the status.

[configFileIsPresent] .true. if configFile was set in GridComp object, .false. otherwise.

[configFile] Return the associated configuration filename. It is an error to query for the configuration filename if none is associated with the GridComp. If unsure, get configFileIsPresent first to determine the status.

[clockIsPresent] .true. if clock was set in GridComp object, .false. otherwise.

[clock] Return the associated Clock. It is an error to query for the Clock if none is associated with the GridComp. If unsure, get clockIsPresent first to determine the status.

[localPet] Return the local PET id within the ESMF_GridComp object.

[petCount] Return the number of PETs in the the ESMF_GridComp object.

[contextflag] Return the ESMF_Context_Flag for this ESMF_GridComp. See section 50.9 for a complete list of valid flags.

[currentMethod] Return the current ESMF_Method_Flag of the ESMF_GridComp execution. See section 50.39 for a complete list of valid options.

[currentPhase] Return the current phase of the ESMF_GridComp execution.

[comptype] Return the Component type. See section 50.8 for a complete list of valid flags.

[vmIsPresent] .true. if vm was set in GridComp object, .false. otherwise.

[vm] Return the associated VM. It is an error to query for the VM if none is associated with the GridComp. If unsure, get vmIsPresent first to determine the status.

[name] Return the name of the ESMF_GridComp.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
16.4.8 ESMF_GridCompGetInternalState - Get private data block pointer

INTERFACE:

subroutine ESMF_GridCompGetInternalState(gridcomp, wrappedDataPointer, rc)

ARGUMENTS:

type(ESMF_GridComp) :: gridcomp

type(wrapper) :: wrappedDataPointer

integer, intent(out) :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Available to be called by an ESMF_GridComp at any time after ESMF_GridCompSetInternalState has been called. Since init, run, and finalize must be separate subroutines, data that they need to share in common can either be module global data, or can be allocated in a private data block and the address of that block can be registered with the framework and retrieved by this call. When running multiple instantiations of an ESMF_GridComp, for example during ensemble runs, it may be simpler to maintain private data specific to each run with private data blocks. A corresponding ESMF_GridCompSetInternalState call sets the data pointer to this block, and this call retrieves the data pointer. Note that the wrappedDataPointer argument needs to be a derived type which contains only a pointer of the type of the data block defined by the user. When making this call the pointer needs to be unassociated. When the call returns, the pointer will now reference the original data block which was set during the previous call to ESMF_GridCompSetInternalState.

Only the last data block set via ESMF_GridCompSetInternalState will be accessible.

CAUTION: This method does not have an explicit Fortran interface. Do not specify argument keywords when calling this method!

The arguments are:

gridcomp An ESMF_GridComp object.

wrappedDataPointer A derived type (wrapper), containing only an unassociated pointer to the private data block.

The framework will fill in the pointer. When this call returns, the pointer is set to the same address set during the last ESMF_GridCompSetInternalState call. This level of indirection is needed to reliably set and retrieve the data block no matter which architecture or compiler is used.

rc Return code; equals ESMF_SUCCESS if there are no errors. Note: unlike most other ESMF routines, this argument is not optional because of implementation considerations.

16.4.9 ESMF_GridCompInitialize - Call the GridComp’s initialize routine

INTERFACE:
recursive subroutine ESMF_GridCompInitialize(gridcomp, &
importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
userRc, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(inout) :: gridcomp

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_State), intent(inout), optional :: importState
type(ESMF_State), intent(inout), optional :: exportState
type(ESMF_Clock), intent(inout), optional :: clock
type(ESMF_Sync_Flag), intent(in), optional :: syncflag
integer, intent(in), optional :: phase
integer, intent(in), optional :: timeout
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user initialization routine for an ESMF_GridComp.

The arguments are:

gridcomp ESMF_GridComp to call initialize routine for.

[importState] ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.
[phase] Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple sub-routines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multi-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.10 ESMF_GridCompIsPetLocal - Inquire if this GridComp is to execute on the calling PET

INTERFACE:

recursive function ESMF_GridCompIsPetLocal(gridcomp, rc)

RETURN VALUE:

logical :: ESMF_GridCompIsPetLocal

ARGUMENTS:

  type(ESMF_GridComp), intent(in) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Inquire if this ESMF_GridComp object is to execute on the calling PET.

The return value is .true. if the component is to execute on the calling PET, .false. otherwise.

The arguments are:

gridcomp ESMF_GridComp queried.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
16.4.11 ESMF_GridCompPrint - Print GridComp information

INTERFACE:

```fortran
subroutine ESMF_GridCompPrint(gridcomp, rc)
```

ARGUMENTS:

```fortran
type(ESMF_GridComp), intent(in) :: gridcomp
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Prints information about an ESMF_GridComp to stdout.

The arguments are:

- **gridcomp** ESMF_GridComp to print.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

16.4.12 ESMF_GridCompReadRestart - Call the GridComp’s read restart routine

INTERFACE:

```fortran
recursive subroutine ESMF_GridCompReadRestart(gridcomp, &
   importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
   userRc, rc)
```

ARGUMENTS:

```fortran
type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_State), intent(inout), optional :: importState
type(ESMF_State), intent(inout), optional :: exportState
type(ESMF_Clock), intent(inout), optional :: clock
type(ESMF_Sync_Flag), intent(in), optional :: syncflag
integer, intent(in), optional :: phase
integer, intent(in), optional :: timeout
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc
```
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument `timeout`. Added argument `timeoutFlag`. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user read restart routine for an ESMF_GridComp.

The arguments are:

- `gridcomp` ESMF_GridComp to call run routine for.
- `[importState]` ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.
- `[exportState]` ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.
- `[clock]` External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.
- `[syncflag]` Blocking behavior of this method call. See section [50.50](#) for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.
- `[phase]` Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, ac commodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.
- `[timeout]` The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The `timeout` argument is only supported for connected dual components.
- `[timeoutFlag]` Returns .true. if the timeout was reached, .false. otherwise. If `timeoutFlag` was not provided, a timeout condition will lead to a return code of `rc \= ESMF_SUCCESS`. Otherwise the return value of `timeoutFlag` is the sole indicator of a timeout condition.
- `[userRc]` Return code set by `userRoutine` before returning.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.
16.4.13  ESMF_GridCompRun - Call the GridComp’s run routine

INTERFACE:

recursive subroutine ESMF_GridCompRun(gridcomp, &
    importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
    userRc, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_State), intent(inout), optional :: importState
    type(ESMF_State), intent(inout), optional :: exportState
    type(ESMF_Clock), intent(inout), optional :: clock
    type(ESMF_Sync_Flag), intent(in), optional :: syncflag
    integer, intent(in), optional :: phase
    integer, intent(in), optional :: timeout
    logical, intent(out), optional :: timeoutFlag
    integer, intent(out), optional :: userRc
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.
Changes made after the 5.2.0r release:

5.3.0  Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user run routine for an ESMF_GridComp.

The arguments are:

gridcomp  ESMF_GridComp to call run routine for.

[importState] ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock]  External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.
[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase] Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.14 ESMF_GridCompServiceLoop - Call the GridComp’s service loop routine

INTERFACE:

recursive subroutine ESMF_GridCompServiceLoop(gridcomp, & importState, exportState, clock, syncflag, port, timeout, timeoutFlag, rc)

ARGUMENTS:

  type(ESMF_GridComp), intent(inout) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_State), intent(inout), optional :: importState
  type(ESMF_State), intent(inout), optional :: exportState
  type(ESMF_Clock), intent(inout), optional :: clock
  type(ESMF_Sync_Flag), intent(in), optional :: syncflag
  integer, intent(in), optional :: port
  integer, intent(in), optional :: timeout
  logical, intent(out), optional :: timeoutFlag
  integer, intent(out), optional :: rc

DESCRIPTION:

Call the ServiceLoop routine for an ESMF_GridComp. This tries to establish a "component tunnel" between the actual Component (calling this routine) and a dual Component connecting to it through a matching SetServices call. The arguments are:

gridcomp ESMF_GridComp to call service loop routine for.
**importState** ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

**exportState** ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

**clock** External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

**syncflag** Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

**port** In case a port number is provided, the "component tunnel" is established using sockets. The actual component side, i.e. the side that calls into ESMF_GridCompServiceLoop(), starts to listen on the specified port as the server. The valid port range is [1024, 65535]. In case the port argument is not specified, the "component tunnel" is established within the same executable using local communication methods (e.g. MPI).

**timeout** The maximum period in seconds that this call will wait for communications with the dual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. (NOTE: Currently this option is only available for socket based component tunnels.)

**timeoutFlag** Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of \( rc \leq \) ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

**rc** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 16.4.15 ESMF_GridCompSet - Set or reset information about the GridComp

**INTERFACE:**

```fortran
subroutine ESMF_GridCompSet(gridcomp, grid, config, &
   configFile, clock, name, rc)
```

**ARGUMENTS:**

```fortran
   type(ESMF_GridComp), intent(inout) :: gridcomp
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_Grid), intent(in), optional :: grid
   type(ESMF_Config), intent(in), optional :: config
   character(len=*), intent(in), optional :: configFile
   type(ESMF_Clock), intent(in), optional :: clock
   character(len=*), intent(in), optional :: name
   integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Sets or resets information about an ESMF_GridComp.

The arguments are:

**gridcomp** ESMF_GridComp to change.

**[grid]** Set the ESMF_Grid associated with the ESMF_GridComp.

**[config]** Set the configuration information for the ESMF_GridComp from this already created ESMF_Config object. If specified, takes priority over configFile.

**[configFile]** Set the configuration filename for this ESMF_GridComp. An ESMF_Config object will be created for this file and attached to the ESMF_GridComp. Superceded by config if both are specified.

**[clock]** Set the private clock for this ESMF_GridComp.

**[name]** Set the name of the ESMF_GridComp.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

16.4.16 ESMF_GridCompSetEntryPoint - Set user routine as entry point for standard GridComp method

INTERFACE:

```
recursive subroutine ESMF_GridCompSetEntryPoint(gridcomp, methodflag, &
       userRoutine, phase, rc)
```

ARGUMENTS:

```
type(ESMF_GridComp), intent(inout) :: gridcomp
    type(ESMF_Method_Flag), intent(in) :: methodflag
    interface
      subroutine userRoutine(gridcomp, importState, exportState, clock, rc)
        use ESMF_CompMod
        use ESMF_StateMod
        use ESMF_ClockMod
        implicit none
        type(ESMF_GridComp) :: gridcomp ! must not be optional
        type(ESMF_State) :: importState ! must not be optional
        type(ESMF_State) :: exportState ! must not be optional
        type(ESMF_Clock) :: clock ! must not be optional
        integer, intent(out) :: rc ! must not be optional
      end subroutine
    end interface
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: phase
    integer, intent(out), optional :: rc
```

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Registers a user-supplied userRoutine as the entry point for one of the predefined Component methodflags. After this call the userRoutine becomes accessible via the standard Component method API.

The arguments are:

gridcomp  An ESMF/GridComp object.

methodflag One of a set of predefined Component methods - e.g. ESMF METHOD INITIALIZE, ESMF METHOD RUN, ESMF METHOD FINALIZE. See section 50.39 for a complete list of valid method options.

userRoutine The user-supplied subroutine to be associated for this Component method. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure. Argument types, intent and order must match the interface signature, and must not have the optional attribute.

[phase] The phase number for multi-phase methods. For single phase methods the phase argument can be omitted. The default setting is 1.

[rc] Return code; equals ESMF SUCCESS if there are no errors.

16.4.17 ESMF_GridCompSetInternalState - Set private data block pointer

INTERFACE:

subroutine ESMF_GridCompSetInternalState(gridcomp, wrappedDataPointer, rc)

ARGUMENTS:

type(ESMF/GridComp) :: gridcomp

type(wrapper) :: wrappedDataPointer

integer, intent(out) :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Available to be called by an ESMF/GridComp at any time, but expected to be most useful when called during the registration process, or initialization. Since init, run, and finalize must be separate subroutines, data that they need to share in common can either be module global data, or can be allocated in a private data block and the address of that block can be registered with the framework and retrieved by subsequent calls. When running multiple instantiations
of an ESMF_GridComp, for example during ensemble runs, it may be simpler to maintain private data specific to each run with private data blocks. A corresponding ESMF_GridCompGetInternalState call retrieves the data pointer.

Only the last data block set via ESMF_GridCompSetInternalState will be accessible.

CAUTION: This method does not have an explicit Fortran interface. Do not specify argument keywords when calling this method!

The arguments are:

gridcomp  An ESMF_GridComp object.

wrappedDataPointer  A pointer to the private data block, wrapped in a derived type which contains only a pointer to the block. This level of indirection is needed to reliably set and retrieve the data block no matter which architecture or compiler is used.

rc  Return code; equals ESMF_SUCCESS if there are no errors. Note: unlike most other ESMF routines, this argument is not optional because of implementation considerations.

16.4.18  ESMF_GridCompSetServices - Call user routine to register GridComp methods

INTERFACE:

    recursive subroutine ESMF_GridCompSetServices(gridcomp, &, userRoutine, userRc, rc)

ARGUMENTS:

    type(ESMF_GridComp), intent(inout) :: gridcomp

    subroutine userRoutine(gridcomp, rc)
        use ESMF_CompMod
        implicit none
        type(ESMF_GridComp) :: gridcomp ! must not be optional
        integer, intent(out) :: rc ! must not be optional
    end subroutine
    end interface

     -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: userRc
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Call into user provided userRoutine which is responsible for setting Component’s Initialize(), Run(), and Finalize() services.

The arguments are:
gridcomp Gridded Component.

userRoutine The Component writer must supply a subroutine with the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

The userRoutine, when called by the framework, must make successive calls to ESMF_GridCompSetEntryPoint() to preset callback routines for standard Component Initialize(), Run(), and Finalize() methods.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.19 ESMF_GridCompSetServices - Call user routine through name lookup, to register GridComp methods

INTERFACE:

! Private name; call using ESMF_GridCompSetServices()

recursive subroutine ESMF_GridCompSetServicesShObj(gridcomp, userRoutine, &
    sharedObj, userRoutineFound, userRc, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(inout) :: gridcomp
character(len=*), intent(in) :: userRoutine
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(len=*), intent(in), optional :: sharedObj
    logical, intent(out), optional :: userRoutineFound
    integer, intent(out), optional :: userRc
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.3.0r Added argument userRoutineFound. The new argument provides a way to test availability without causing error conditions.

DESCRIPTION:
Call into a user provided routine which is responsible for setting Component's Initialize(), Run(), and Finalize() services. The named `userRoutine` must exist in the executable, or in the shared object specified by `sharedObj`. In the latter case all of the platform specific details about dynamic linking and loading apply.

The arguments are:

- **gridcomp** Gridded Component.
- **userRoutine** Name of routine to be called, specified as a character string. The Component writer must supply a subroutine with the exact interface shown for `userRoutine` below. Arguments must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

**INTERFACE:**

```fortran
interface
  subroutine userRoutine(gridcomp, rc)
    type(ESMF_GridComp) :: gridcomp ! must not be optional
    integer, intent(out) :: rc ! must not be optional
  end subroutine
end interface
```

**DESCRIPTION:**

The `userRoutine`, when called by the framework, must make successive calls to `ESMF_GridCompSetEntryPoint()` to preset callback routines for standard Component Initialize(), Run(), and Finalize() methods.

- **[sharedObj]** Name of shared object that contains `userRoutine`. If the `sharedObj` argument is not provided the executable itself will be searched for `userRoutine`.
- **[userRoutineFound]** Report back whether the specified `userRoutine` was found and executed, or was not available. If this argument is present, not finding the `userRoutine` will not result in returning an error in `rc`. The default is to return an error if the `userRoutine` cannot be found.
- **[userRc]** Return code set by `userRoutine` before returning.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 16.4.20 ESMF_GridCompSetServices - Set to serve as Dual Component for an Actual Component

**INTERFACE:**

```fortran
! Private name; call using ESMF_GridCompSetServices()
recursive subroutine ESMF_GridCompSetServicesComp(gridcomp, &
  actualGridcomp, rc)
```

**ARGUMENTS:**

- `gridcomp` Gridded Component.
- `actualGridcomp` Actual Component.
type (ESMF_GridComp), intent(inout) :: gridcomp
type (ESMF_GridComp), intent(in) :: actualGridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

DESCRIPTION:

Set the services of a Gridded Component to serve a "dual" Component for an "actual" Component. The component
tunnel is VM based.

The arguments are:

gridcomp  Dual Gridded Component.
actualGridcomp  Actual Gridded Component.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

16.4.21  ESMF_GridCompSetServices - Set to serve as Dual Component for an Actual Component through
socket

INTERFACE:

! Private name; call using ESMF_GridCompSetServices()
recursive subroutine ESMF_GridCompSetServicesSock(gridcomp, port, &
server, timeout, timeoutFlag, rc)

ARGUMENTS:

  type (ESMF_GridComp), intent(inout) :: gridcomp
  integer, intent(in) :: port
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  character(len=*), intent(in), optional :: server
  integer, intent(in), optional :: timeout
  logical, intent(out), optional :: timeoutFlag
  integer, intent(out), optional :: rc

DESCRIPTION:

Set the services of a Gridded Component to serve a "dual" Component for an "actual" Component. The component
tunnel is socket based.

The arguments are:

gridcomp  Dual Gridded Component.
port  Port number under which the actual component is being served. The valid port range is [1024, 65535].

[server]  Server name where the actual component is being served. The default, i.e. if the server argument was not
provided, is localhost.
[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

### 16.4.22 ESMF_GridCompSetVM - Call user routine to set GridComp VM properties

**INTERFACE:**

```fortran
recursive subroutine ESMF_GridCompSetVM(gridcomp, userRoutine, &
userRc, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_GridComp), intent(inout) :: gridcomp
interface
  subroutine userRoutine(gridcomp, rc)
    use ESMF_CompMod
    implicit none
    type(ESMF_GridComp) :: gridcomp ! must not be optional
    integer, intent(out) :: rc ! must not be optional
  end subroutine
end interface
```

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

```fortran
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

 Optionally call into user provided userRoutine which is responsible for setting Component’s VM properties.

 The arguments are:

**gridcomp** Gridded Component.

**userRoutine** The Component writer must supply a subroutine with the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

 The subroutine, when called by the framework, is expected to use any of the ESMF_GridCompSetVMxxx() methods to set the properties of the VM associated with the Gridded Component.
Return code set by `userRoutine` before returning.

Return code; equals `ESMF_SUCCESS` if there are no errors.

16.4.23 ESMF_GridCompSetVM - Call user routine through name lookup, to set GridComp VM properties

INTERFACE:

```fortran
recursive subroutine ESMF_GridCompSetVM(gridcomp, userRoutine, &
sharedObj, userRc, rc)
```

ARGUMENTS:

```fortran
type(ESMF_GridComp), intent(inout) :: gridcomp
character(len=*) , intent(in) :: userRoutine
character(len=*) , intent(in), optional :: sharedObj
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Optionally call into user provided `userRoutine` which is responsible for setting Component’s VM properties. The named `userRoutine` must exist in the executable, or in the shared object specified by `sharedObj`. In the latter case all of the platform specific details about dynamic linking and loading apply.

The arguments are:

- **gridcomp** Gridded Component.
- **userRoutine** Routine to be called, specified as a character string. The Component writer must supply a subroutine with the exact interface shown for `userRoutine` below. Arguments must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

INTERFACE:

```fortran
interface userRoutine(gridcomp, rc)
    type(ESMF_GridComp) :: gridcomp ! must not be optional
    integer, intent(out) :: rc ! must not be optional
end subroutine
end interface
```
DESCRIPTION:

The subroutine, when called by the framework, is expected to use any of the ESMF_GridCompSetVMxxx() methods to set the properties of the VM associated with the Gridded Component.

[sharedObj] Name of shared object that contains userRoutine. If the sharedObj argument is not provided the executable itself will be searched for userRoutine.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

16.4.24 ESMF_GridCompSetVMMaxPEs - Associate PEs with PETs in GridComp VM

INTERFACE:

subroutine ESMF_GridCompSetVMMaxPEs(gridcomp, & maxPeCountPerPet, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)

ARGUMENTS:

type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: maxPeCountPerPet
integer, intent(in), optional :: prefIntraProcess
integer, intent(in), optional :: prefIntraSsi
integer, intent(in), optional :: prefInterSsi
integer, intent(out), optional :: rc

DESCRIPTION:

Set characteristics of the ESMF_VM for this ESMF_GridComp. Attempts to associate up to maxPeCountPerPet PEs with each PET. Only PEs that are located on the same single system image (SSI) can be associated with the same PET. Within this constraint the call tries to get as close as possible to the number specified by maxPeCountPerPet.

The other constraint to this call is that the number of PEs is preserved. This means that the child Component in the end is associated with as many PEs as the parent Component provided to the child. The number of child PETs however is adjusted according to the above rule.

The typical use of ESMF_GridCompSetVMMaxPEs() is to allocate multiple PEs per PET in a Component for user-level threading, e.g. OpenMP.

The arguments are:

gridcomp ESMF_GridComp to set the ESMF_VM for.
[maxPeCountPerPet] Maximum number of PEs on each PET. Default for each SSI is the local number of PEs.
Communication preference within a single system image (SSI). Currently options not documented. Use default.

Communication preference between different single system images (SSIs). Currently options not documented. Use default.

Return code; equals ESMF_SUCCESS if there are no errors.

16.4.25 ESMF_GridCompSetVMMaxThreads - Set multi-threaded PETs in GridComp VM

INTERFACE:

```fortran
subroutine ESMF_GridCompSetVMMaxThreads(gridcomp, &
             maxPetCountPerVas, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)
```

ARGUMENTS:

```fortran
type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: maxPetCountPerVas
integer, intent(in), optional :: prefIntraProcess
integer, intent(in), optional :: prefIntraSsi
integer, intent(in), optional :: prefInterSsi
integer, intent(out), optional :: rc
```

DESCRIPTION:

Set characteristics of the ESMF_VM for this ESMF_GridComp. Attempts to provide maxPetCountPerVas threaded PETs in each virtual address space (VAS). Only as many threaded PETs as there are PEs located on the single system image (SSI) can be associated with the VAS. Within this constraint the call tries to get as close as possible to the number specified by maxPetCountPerVas.

The other constraint to this call is that the number of PETs is preserved. This means that the child Component in the end is associated with as many PETs as the parent Component provided to the child. The threading level of the child PETs however is adjusted according to the above rule.

The typical use of ESMF_GridCompSetVMMaxThreads() is to run a Component multi-threaded with groups of PETs executing within a common virtual address space.

The arguments are:

- `gridcomp` ESMF_GridComp to set the ESMF_VM for.
- `maxPetCountPerVas` Maximum number of threaded PETs in each virtual address space (VAS). Default for each SSI is the local number of PEs.
- `prefIntraSsi` Communication preference within a single system image (SSI). Currently options not documented. Use default.
[prefInterSsi] Communication preference between different single system images (SSIs). *Currently options not documented. Use default.*

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

**16.4.26 ESMF_GridCompSetVMMinThreads - Set a reduced threading level in GridComp VM**

**INTERFACE:**

```fortran
subroutine ESMF_GridCompSetVMMinThreads(gridcomp, &
         maxPeCountPerPet, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: maxPeCountPerPet
integer, intent(in), optional :: prefIntraProcess
integer, intent(in), optional :: prefIntraSsi
integer, intent(in), optional :: prefInterSsi
integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Set characteristics of the ESMF_VM for this ESMF_GridComp. Reduces the number of threaded PETs in each VAS. The max argument may be specified to limit the maximum number of PEs that a single PET can be associated with.

Several constraints apply: 1) the number of PEs cannot change, 2) PEs cannot migrate between single system images (SSIs), 3) the number of PETs cannot increase, only decrease, 4) PETs cannot migrate between virtual address spaces (VASs), nor can VASs migrate between SSIs.

The typical use of ESMF_GridCompSetVMMinThreads () is to run a Component across a set of single-threaded PETs.

The arguments are:

- **gridcomp** ESMF_GridComp to set the ESMF_VM for.
- **maxPeCountPerPet** Maximum number of PEs on each PET. Default for each SSI is the local number of PEs.
- **prefIntraProcess** Communication preference within a single process. *Currently options not documented. Use default.*
- **prefIntraSsi** Communication preference within a single system image (SSI). *Currently options not documented. Use default.*
- **prefInterSsi** Communication preference between different single system images (SSIs). *Currently options not documented. Use default.*

- **rc** Return code; equals ESMF_SUCCESS if there are no errors.
16.4.27  ESMF_GridCompValidate - Check validity of a GridComp

INTERFACE:

subroutine ESMF_GridCompValidate(gridcomp, rc)

ARGUMENTS:

  type(ESMF_GridComp), intent(in) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Currently all this method does is to check that the gridcomp was created.
The arguments are:

gridcomp  ESMF_GridComp to validate.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

16.4.28  ESMF_GridCompWait - Wait for a GridComp to return

INTERFACE:

subroutine ESMF_GridCompWait(gridcomp, syncflag, &
  timeout, timeoutFlag, userRc, rc)

ARGUMENTS:

  type(ESMF_GridComp), intent(inout) :: gridcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_Sync_Flag), intent(in), optional :: syncflag
  integer, intent(in), optional :: timeout
  logical, intent(out), optional :: timeoutFlag
  integer, intent(out), optional :: userRc
  integer, intent(out), optional :: rc

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument `timeout`. Added argument `timeoutFlag`. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

When executing asynchronously, wait for an `ESMF_GridComp` to return.

The arguments are:

- **gridcomp** `ESMF_GridComp` to wait for.

  - `[syncflag]` Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is `ESMF_SYNC_VASBLOCKING` which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

  - `[timeout]` The maximum period in seconds the actual component is allowed to execute a previously envoked component method before it must communicate back to the dual component. If the actual component does not communicate back in the specified time, a timeout condition is raised on the dual side (this side). The default is 3600, i.e. 1 hour. The `timeout` argument is only supported for connected dual components.

  - `[timeoutFlag]` Returns `.true.` if the timeout was reached, `.false.` otherwise. If `timeoutFlag` was *not* provided, a timeout condition will lead to a return code of `rc \= ESMF_SUCCESS`. Otherwise the return value of `timeoutFlag` is the sole indicator of a timeout condition.

  - `[userRc]` Return code set by `userRoutine` before returning.

  - `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.

16.4.29 `ESMF_GridCompWriteRestart` - Call the GridComp’s write restart routine

INTERFACE:

```fortran
recursive subroutine ESMF_GridCompWriteRestart(gridcomp, &
    importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
    userRc, rc)
```

ARGUMENTS:

```fortran
    type(ESMF_GridComp), intent(inout) :: gridcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_State), intent(inout), optional :: importState
    type(ESMF_State), intent(inout), optional :: exportState
```

117
type (ESMF_Clock), intent(inout), optional :: clock

type (ESMF_Sync_Flag), intent(in), optional :: syncflag

integer, intent(in), optional :: phase

integer, intent(in), optional :: timeout

logical, intent(out), optional :: timeoutFlag

integer, intent(out), optional :: userRc

integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user write restart routine for an ESMF_GridComp.

The arguments are:

gridcomp  ESMF_GridComp to call run routine for.

[importState]  ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState]  ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock]  External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

[syncflag]  Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase]  Component providers must document whether their each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout]  The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.
Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of \( rc \neq \text{ESMF\_SUCCESS} \). Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF\_SUCCESS if there are no errors.

17 CplComp Class

17.1 Description

In a large, multi-component application such as a weather forecasting or climate prediction system running within ESMF, physical domains and major system functions are represented as Gridded Components (see Section 16.1). A Coupler Component, or ESMF\_CplComp, arranges and executes the data transformations between the Gridded Components. Ideally, Coupler Components should contain all the information about inter-component communication for an application. This enables the Gridded Components in the application to be used in multiple contexts; that is, used in different coupled configurations without changes to their source code. For example, the same atmosphere might in one case be coupled to an ocean in a hurricane prediction model, and to a data assimilation system for numerical weather prediction in another. A single Coupler Component can couple two or more Gridded Components.

Like Gridded Components, Coupler Components have two parts, one that is provided by the user and another that is part of the framework. The user-written portion of the software is the coupling code necessary for a particular exchange between Gridded Components. This portion of the Coupler Component code must be divided into separately callable initialize, run, and finalize methods. The interfaces for these methods are prescribed by ESMF.

The term “user-written” is somewhat misleading here, since within a Coupler Component the user can leverage ESMF infrastructure software for regridding, redistribution, lower-level communications, calendar management, and other functions. However, ESMF is unlikely to offer all the software necessary to customize a data transfer between Gridded Components. For instance, ESMF does not currently offer tools for unit transformations or time averaging operations, so users must manage those operations themselves.

The second part of a Coupler Component is the ESMF\_CplComp derived type within ESMF. The user must create one of these types to represent a specific coupling function, such as the regular transfer of data between a data assimilation system and an atmospheric model.

The user-written part of a Coupler Component is associated with an ESMF\_CplComp derived type through a routine called ESMF\_SetServices(). This is a routine that the user must write and declare public. Inside the ESMF\_SetServices() routine the user must call ESMF\_SetEntryPoint() methods that associate a standard ESMF operation with the name of the corresponding Fortran subroutine in their user code. For example, a user routine called “couplerInit” might be associated with the standard initialize routine in a Coupler Component.

17.2 Use and Examples

A Coupler Component manages the transformation of data between Components. It contains a list of State objects and the operations needed to make them compatible, including such things as regridding and unit conversion. Coupler Components are user-written, following prescribed ESMF interfaces and, wherever desired, using ESMF infrastructure tools.

\(^2\)It is not necessary to create a Coupler Component for each individual data transfer.
17.2.1 Implement a user-code SetServices routine

Every ESMF_CplComp is required to provide and document a public set services routine. It can have any name, but must follow the declaration below: a subroutine which takes an ESMF_CplComp as the first argument, and an integer return code as the second. Both arguments are required and must not be declared as optional. If an intent is specified in the interface it must be intent(inout) for the first and intent(out) for the second argument.

The set services routine must call the ESMF method ESMF_CplCompSetEntryPoint() to register with the framework what user-code subroutines should be called to initialize, run, and finalize the component. There are additional routines which can be registered as well, for checkpoint and restart functions.

Note that the actual subroutines being registered do not have to be public to this module; only the set services routine itself must be available to be used by other code.

```fortran
! Example Coupler Component
module ESMF_CouplerEx

! ESMF Framework module
use ESMF
implicit none
public CPL_SetServices
contains

subroutine CPL_SetServices(comp, rc)
type(ESMF_CplComp) :: comp ! must not be optional
integer, intent(out) :: rc ! must not be optional

! Set the entry points for standard ESMF Component methods
call ESMF_CplCompSetEntryPoint(comp, ESMF_METHOD_INITIALIZE, &
userRoutine=CPL_Init, rc=rc)
call ESMF_CplCompSetEntryPoint(comp, ESMF_METHOD_RUN, &
userRoutine=CPL_Run, rc=rc)
call ESMF_CplCompSetEntryPoint(comp, ESMF_METHOD_FINALIZE, &
userRoutine=CPL_Final, rc=rc)
rc = ESMF_SUCCESS
end subroutine
```

17.2.2 Implement a user-code Initialize routine

When a higher level component is ready to begin using an ESMF_CplComp, it will call its initialize routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

At initialization time the component can allocate data space, open data files, set up initial conditions; anything it needs to do to prepare to run.

The `rc` return code should be set if an error occurs, otherwise the value `ESMF_SUCCESS` should be returned.

```fortran
subroutine CPL_Init(comp, importState, exportState, clock, rc)
```
type(ESMF_CplComp) :: comp ! must not be optional
type(ESMF_State) :: importState ! must not be optional
type(ESMF_State) :: exportState ! must not be optional
type(ESMF_Clock) :: clock ! must not be optional
integer, intent(out) :: rc ! must not be optional

print *, "Coupler Init starting"
! Add whatever code here needed
! Precompute any needed values, fill in any initial values
! needed in Import States
rc = ESMF_SUCCESS
print *, "Coupler Init returning"
end subroutine CPL_Init

17.2.3 Implement a user-code Run routine

During the execution loop, the run routine may be called many times. Each time it should read data from the importState, use the clock to determine what the current time is in the calling component, compute new values or process the data, and produce any output and place it in the exportState.

When a higher level component is ready to use the ESMF_CplComp it will call its run routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

It is expected that this is where the bulk of the model computation or data analysis will occur.

The rc return code should be set if an error occurs, otherwise the value ESMF_SUCCESS should be returned.

subroutine CPL_Run(comp, importState, exportState, clock, rc)
type(ESMF_CplComp) :: comp ! must not be optional
type(ESMF_State) :: importState ! must not be optional
type(ESMF_State) :: exportState ! must not be optional
type(ESMF_Clock) :: clock ! must not be optional
integer, intent(out) :: rc ! must not be optional

print *, "Coupler Run starting"
! Add whatever code needed here to transform Export state data
! into Import states for the next timestep.
rc = ESMF_SUCCESS
print *, "Coupler Run returning"
end subroutine CPL_Run
17.2.4 Implement a user-code Finalize routine

At the end of application execution, each ESMF_CplComp should deallocate data space, close open files, and flush final results. These functions should be placed in a finalize routine.

The component writer must supply a subroutine with the exact interface shown below. Arguments must not be declared as optional, and the types and order must match.

The rc return code should be set if an error occurs, otherwise the value ESMF_SUCCESS should be returned.

```
subroutine CPL_Final(comp, importState, exportState, clock, rc)
    type(ESMF_CplComp) :: comp ! must not be optional
    type(ESMF_State) :: importState ! must not be optional
    type(ESMF_State) :: exportState ! must not be optional
    type(ESMF_Clock) :: clock ! must not be optional
    integer, intent(out) :: rc ! must not be optional

    print *, "Coupler Final starting"

    ! Add whatever code needed here to compute final values and
    ! finish the computation.

    rc = ESMF_SUCCESS

    print *, "Coupler Final returning"
end subroutine CPL_Final
```

17.2.5 Implement a user-code SetVM routine

Every ESMF_CplComp can optionally provide and document a public set vm routine. It can have any name, but must follow the declaration below: a subroutine which takes an ESMF_CplComp as the first argument, and an integer return code as the second. Both arguments are required and must not be declared as optional. If an intent is specified in the interface it must be intent(inout) for the first and intent(out) for the second argument.

The set vm routine is the only place where the child component can use the ESMF_CplCompSetVMMaxPEs(), or ESMF_CplCompSetVMMaxThreads(), or ESMF_CplCompSetVMMinThreads() call to modify aspects of its own VM.

A component’s VM is started up right before its set services routine is entered. ESMF_CplCompSetVM() is executing in the parent VM, and must be called before ESMF_CplCompSetServices().

```
subroutine GComp_SetVM(comp, rc)
    type(ESMF_CplComp) :: comp ! must not be optional
    integer, intent(out) :: rc ! must not be optional

    type(ESMF_VM) :: vm
    logical :: pthreadsEnabled

    ! Test for Pthread support, all SetVM calls require it
```
call ESMF_VMGetGlobal(vm, rc=rc)
call ESMF_VMGet(vm, pthreadsEnabledFlag=pthreadsEnabled, rc=rc)

if (pthreadsEnabled) then
  ! run PETs single-threaded
  call ESMF_CplCompSetVMMinThreads(comp, rc=rc)
endif

rc = ESMF_SUCCESS

end subroutine

derive module ESMF_CouplerEx

17.3 Restrictions and Future Work

1. **No optional arguments.** User-written routines called by SetServices, and registered for Initialize, Run and Finalize, must not declare any of the arguments as optional.

2. **No Transforms.** Components must exchange data through ESMF_State objects. The input data are available at the time the component code is called, and data to be returned to another component are available when that code returns.

3. **No automatic unit conversions.** The ESMF framework does not currently contain tools for performing unit conversions, operations that are fairly standard within Coupler Components.

4. **No accumulator.** The ESMF does not have an accumulator tool, to perform time averaging of fields for coupling. This is likely to be developed in the near term.

17.4 Class API

17.4.1 ESMF_CplCompAssignment(=) - CplComp assignment

**INTERFACE:**

```
interface assignment (=)
cplcomp1 = cplcomp2
```

**ARGUMENTS:**

```
type (ESMF_CplComp) :: cplcomp1
type (ESMF_CplComp) :: cplcomp2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Assign cplcomp1 as an alias to the same ESMF CplComp object in memory as cplcomp2. If cplcomp2 is invalid, then cplcomp1 will be equally invalid after the assignment.

The arguments are:

- **cplcomp1** The ESMF_CplComp object on the left hand side of the assignment.
- **cplcomp2** The ESMF_CplComp object on the right hand side of the assignment.

---

17.4.2 ESMF_CplCompOperator(==) - CplComp equality operator

INTERFACE:

```fortran
interface operator(==)
   if (cplcomp1 == cplcomp2) then ... endif
   OR
   result = (cplcomp1 == cplcomp2)
end interface
```

RETURN VALUE:

```
logical :: result
```

ARGUMENTS:

- `cplcomp1` type(ESMF_CplComp), intent(in) :: cplcomp1
- `cplcomp2` type(ESMF_CplComp), intent(in) :: cplcomp2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether cplcomp1 and cplcomp2 are valid aliases to the same ESMF CplComp object in memory. For a more general comparison of two ESMF CplComps, going beyond the simple alias test, the ESMF_CplCompMatch() function (not yet implemented) must be used.

The arguments are:

- **cplcomp1** The ESMF_CplComp object on the left hand side of the equality operation.
- **cplcomp2** The ESMF_CplComp object on the right hand side of the equality operation.
17.4.3  ESMF_CplCompOperator(/=) - CplComp not equal operator

INTERFACE:

interface operator(/=)
  
  if (cplcomp1 /= cplcomp2) then ... endif
  
  result = (cplcomp1 /= cplcomp2)

RETURN VALUE:

logical :: result

ARGUMENTS:

  type(ESMF_CplComp), intent(in) :: cplcomp1
  type(ESMF_CplComp), intent(in) :: cplcomp2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether cplcomp1 and cplcomp2 are not valid aliases to the same ESMF CplComp object in memory. For a more general comparison of two ESMF CplComps, going beyond the simple alias test, the ESMF_CplCompMatch() function (not yet implemented) must be used.

The arguments are:

cplcomp1 The ESMF_CplComp object on the left hand side of the non-equality operation.

cplcomp2 The ESMF_CplComp object on the right hand side of the non-equality operation.

---

17.4.4  ESMF_CplCompCreate - Create a CplComp

INTERFACE:

recursive function ESMF_CplCompCreate(config, configFile, &
clock, petList, contextflag, name, rc)

RETURN VALUE:

type(ESMF_CplComp) :: ESMF_CplCompCreate

ARGUMENTS:
The following arguments require argument keyword syntax (e.g. rc=rc).

- type(ESMF_Config), intent(in), optional :: config
- character(len=*), intent(in), optional :: config
- type(ESMF_Clock), intent(in), optional :: clock
- integer, intent(in), optional :: petList(:)
- type(ESMF_Context_Flag), intent(in), optional :: contextflag
- character(len= *), intent(in), optional :: name
- integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This interface creates an ESMF_CplComp object. By default, a separate VM context will be created for each component. This implies creating a new MPI communicator and allocating additional memory to manage the VM resources. When running on a large number of processors, creating a separate VM for each component could be both time and memory inefficient. If the application is sequential, i.e., each component is running on all the PETs of the global VM, it will be more efficient to use the global VM instead of creating a new one. This can be done by setting contextflag to ESMF_CONTEXT_PARENT_VM. The return value is the new ESMF_CplComp.

The arguments are:

- [config] An already-created ESMF_Config configuration object from which the new component can read in namelist-type information to set parameters for this run. If both are specified, this object takes priority over configFile.
- [configFile] The filename of an ESMF_Config format file. If specified, this file is opened, an ESMF_Config configuration object is created for the file, and attached to the new component. The user can call ESMF_CplCompGet() to get and use the object. If both are specified, the config object takes priority over this one.
- [clock] Component-specific ESMF_Clock. This clock is available to be queried and updated by the new ESMF_CplComp as it chooses. This should not be the parent component clock, which should be maintained and passed down to the initialize/run/finalize routines separately.
- [petList] List of parent PETs given to the created child component by the parent component. If petList is not specified all of the parent PETs will be given to the child component. The order of PETs in petList determines how the child local PETs refer back to the parent PETs.
- [contextflag] Specify the component’s VM context. The default context is ESMFCONTEXT_PARENT_VM. See section 50.9 for a complete list of valid flags.
- [name] Name of the newly-created ESMF_CplComp. This name can be altered from within the ESMF_CplComp code once the initialization routine is called.
- [rc] Return code; equals ESMF_SUCCESS if there are no errors.
17.4.5 ESMF_CplCompDestroy - Release resources associated with a CplComp

INTERFACE:

    recursive subroutine ESMF_CplCompDestroy(cplcomp, &
      timeout, timeoutFlag, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: timeout
    logical, intent(out), optional :: timeoutFlag
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

- 5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Destroys an ESMF_CplComp, releasing the resources associated with the object.

The arguments are:

- **cplcomp** Release all resources associated with this ESMF_CplComp and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.
- **timeout** The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.
- **timeoutFlag** Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc != ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.
- **rc** Return code; equals ESMF_SUCCESS if there are no errors.
17.4.6 ESMF_CplCompFinalize - Call the CplComp’s finalize routine

INTERFACE:

recursive subroutine ESMF_CplCompFinalize(cplcomp, &
importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
userRc, rc)

ARGUMENTS:

  type(ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_State), intent(inout), optional :: importState
  type(ESMF_State), intent(inout), optional :: exportState
  type(ESMF_Clock), intent(inout), optional :: clock
  type(ESMF_Sync_Flag), intent(in), optional :: syncflag
  integer, intent(in), optional :: phase
  integer, intent(in), optional :: timeout
  logical, intent(out), optional :: timeoutFlag
  integer, intent(out), optional :: userRc
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release. Changes made after the 5.2.0r release:

  5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user-supplied finalization routine for an ESMF_CplComp.

The arguments are:

cplcomp The ESMF_CplComp to call finalize routine for.

[importState] ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.
[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase] Component providers must document whether their each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.7 ESMF_CplCompGet - Get CplComp information

INTERFACE:

subroutine ESMF_CplCompGet(cplcomp, configIsPresent, config, &
    configFileIsPresent, configFile, clockIsPresent, clock, localPet, &
    petCount, contextflag, currentMethod, currentPhase, vmIsPresent, &
    vm, name, rc)

ARGUMENTS:

  type(ESMF_CplComp), intent(in) :: cplcomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical, intent(out), optional :: configIsPresent
  type(ESMF_Config), intent(out), optional :: config
  logical, intent(out), optional :: configFileIsPresent
  character(len=*), intent(out), optional :: configFile
  logical, intent(out), optional :: clockIsPresent
  type(ESMF_Clock), intent(out), optional :: clock
  integer, intent(out), optional :: localPet
  integer, intent(out), optional :: petCount
  type(ESMF_Context_Flag), intent(out), optional :: contextflag
  type(ESMF_Method_Flag), intent(out), optional :: currentMethod
  integer, intent(out), optional :: currentPhase
  logical, intent(out), optional :: vmIsPresent
  type(ESMF_VM), intent(out), optional :: vm
  character(len=*), intent(out), optional :: name
  integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get information about an ESMF_CplComp object.

The arguments are:

- cplcomp: The ESMF_CplComp object being queried.
- [configIsPresent]: .true. if config was set in CplComp object, .false. otherwise.
- [config]: Return the associated Config. It is an error to query for the Config if none is associated with the CplComp. If unsure, get configIsPresent first to determine the status.
- [configFileIsPresent]: .true. if configFile was set in CplComp object, .false. otherwise.
- [configFile]: Return the associated configuration filename. It is an error to query for the configuration filename if none is associated with the CplComp. If unsure, get configFileIsPresent first to determine the status.
- [clockIsPresent]: .true. if clock was set in CplComp object, .false. otherwise.
- [clock]: Return the associated Clock. It is an error to query for the Clock if none is associated with the CplComp. If unsure, get clockIsPresent first to determine the status.
- [localPet]: Return the local PET id within the ESMF_CplComp object.
- [petCount]: Return the number of PETs in the ESMF_CplComp object.
- [contextflag]: Return the ESMF_Context_Flag for this ESMF_CplComp. See section 50.9 for a complete list of valid flags.
- [currentMethod]: Return the current ESMF_Method_Flag of the ESMF_CplComp execution. See section 50.39 for a complete list of valid options.
- [currentPhase]: Return the current phase of the ESMF_CplComp execution.
- [vmIsPresent]: .true. if vm was set in CplComp object, .false. otherwise.
- [vm]: Return the associated VM. It is an error to query for the VM if none is associated with the CplComp. If unsure, get vmIsPresent first to determine the status.
- [name]: Return the name of the ESMF_CplComp.
- [rc]: Return code; equals ESMF_SUCCESS if there are no errors.

17.4.8 ESMF_CplCompGetInternalState - Get private data block pointer

INTERFACE:

subroutine ESMF_CplCompGetInternalState(cplcomp, wrappedDataPointer, rc)
ARGUMENTS:

```fortran
type(ESMF_CplComp) :: cplcomp

type(wrapper) :: wrappedDataPointer

integer, intent(out) :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Available to be called by an ESMF_CplComp at any time after ESMF_CplCompSetInternalState has been called. Since init, run, and finalize must be separate subroutines, data that they need to share in common can either be module global data, or can be allocated in a private data block and the address of that block can be registered with the framework and retrieved by this call. When running multiple instantiations of an ESMF_CplComp, for example during ensemble runs, it may be simpler to maintain private data specific to each run with private data blocks. A corresponding ESMF_CplCompSetInternalState call sets the data pointer to this block, and this call retrieves the data pointer. Note that the wrappedDataPointer argument needs to be a derived type which contains only a pointer of the type of the data block defined by the user. When making this call the pointer needs to be unassociated. When the call returns, the pointer will now reference the original data block which was set during the previous call to ESMF_CplCompSetInternalState.

Only the last data block set via ESMF_CplCompSetInternalState will be accessible.

CAUTION: This method does not have an explicit Fortran interface. Do not specify argument keywords when calling this method!

The arguments are:

**cplcomp** An ESMF_CplComp object.

**wrappedDataPointer** A derived type (wrapper), containing only an unassociated pointer to the private data block. The framework will fill in the pointer. When this call returns, the pointer is set to the same address set during the last ESMF_CplCompSetInternalState call. This level of indirection is needed to reliably set and retrieve the data block no matter which architecture or compiler is used.

**rc** Return code; equals ESMF_SUCCESS if there are no errors. Note: unlike most other ESMF routines, this argument is not optional because of implementation considerations.

17.4.9 ESMF_CplCompInitialize - Call the CplComp’s initialize routine

INTERFACE:

```fortran
recursive subroutine ESMF_CplCompInitialize(cplcomp, &
   importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
   userRc, rc)
```

ARGUMENTS:
type (ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_State), intent(inout), optional :: importState
type (ESMF_State), intent(inout), optional :: exportState
type (ESMF_Clock), intent(inout), optional :: clock
type (ESMF_Sync_Flag), intent(in), optional :: syncflag
integer, intent(in), optional :: phase
integer, intent(in), optional :: timeout
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release. Changes made after the 5.2.0r release:
  5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user initialization routine for an ESMF_CplComp.

The arguments are:

cplcomp ESMF_CplComp to call initialize routine for.
[importState] ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.
[exportState] ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.
[clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.
[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.
[phase] Component providers must document whether their each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.
[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.10 ESMF_CplCompIsPetLocal - Inquire if this CplComp is to execute on the calling PET

INTERFACE:

recursive function ESMF_CplCompIsPetLocal(cplcomp, rc)

RETURN VALUE:

logical :: ESMF_CplCompIsPetLocal

ARGUMENTS:

type(ESMF_CplComp), intent(in) :: cplcomp
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Inquire if this ESMF_CplComp object is to execute on the calling PET.

The return value is .true. if the component is to execute on the calling PET, .false. otherwise.

The arguments are:

cplcomp ESMF_CplComp queried.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
17.4.11 ESMF_CplCompPrint - Print CplComp information

INTERFACE:

    subroutine ESMF_CplCompPrint(cplcomp, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(in) :: cplcomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Prints information about an ESMF_CplComp to stdout.

The arguments are:

cplcomp  ESMF_CplComp to print.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

17.4.12 ESMF_CplCompReadRestart – Call the CplComp’s read restart routine

INTERFACE:

    recursive subroutine ESMF_CplCompReadRestart(cplcomp, &
        importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
        userRc, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(inout) :: cplcomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_State), intent(inout), optional :: importState
    type(ESMF_State), intent(inout), optional :: exportState
    type(ESMF_Clock), intent(inout), optional :: clock
    type(ESMF_Sync_Flag), intent(in), optional :: syncflag
    integer, intent(in), optional :: phase
    integer, intent(in), optional :: timeout
    logical, intent(inout), optional :: timeoutFlag
    integer, intent(inout), optional :: userRc
    integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user read restart routine for an ESMF_CplComp.

The arguments are:

cplcomp ESMF_CplComp to call run routine for.

[importState] ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase] Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accomodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \( \not\equiv \) ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
17.4.13  ESMF_CplCompRun - Call the CplComp’s run routine

INTERFACE:

recursive subroutine ESMF_CplCompRun(cplcomp, &
   importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
   userRc, rc)

ARGUMENTS:

   type(ESMF_CplComp), intent(inout) :: cplcomp
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_State), intent(inout), optional :: importState
   type(ESMF_State), intent(inout), optional :: exportState
   type(ESMF_Clock), intent(inout), optional :: clock
   type(ESMF_Sync_Flag), intent(in), optional :: syncflag
   integer, intent(in), optional :: phase
   integer, intent(in), optional :: timeout
   logical, intent(out), optional :: timeoutFlag
   integer, intent(out), optional :: userRc
   integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0  Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user run routine for an ESMF_CplComp.

The arguments are:

cplcomp  ESMF_CplComp to call run routine for.

[importState]  ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState]  ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

[clock]  External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.
[syncflag] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[phase] Component providers must document whether each of their routines are single-phase or multi-phase. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multi-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.14 ESMF_CplCompServiceLoop - Call the CplComp’s service loop routine

INTERFACE:

recursive subroutine ESMF_CplCompServiceLoop(cplcomp, &
importState, exportState, clock, syncflag, port, timeout, timeoutFlag, rc)

ARGUMENTS:

type(ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_State), intent(inout), optional :: importState
type(ESMF_State), intent(inout), optional :: exportState
type(ESMF_Clock), intent(inout), optional :: clock
type(ESMF_Sync_Flag), intent(in), optional :: syncflag
integer, intent(in), optional :: port
integer, intent(in), optional :: timeout
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: rc

DESCRIPTION:

Call the ServiceLoop routine for an ESMF_CplComp. This tries to establish a "component tunnel" between the actual Component (calling this routine) and a dual Component connecting to it through a matching SetServices call.

The arguments are:

cplcomp ESMF_CplComp to call service loop routine for.
[importState] ESMF_State containing import data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

[exportState] ESMF_State containing export data for coupling. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

clock] External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

SYNCFLAG] Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

[port] In case a port number is provided, the "component tunnel" is established using sockets. The actual component side, i.e. the side that calls into ESMF_CplCompServiceLoop(), starts to listen on the specified port as the server. The valid port range is [1024, 65535]. In case the port argument is not specified, the "component tunnel" is established within the same executable using local communication methods (e.g. MPI).

timeout] The maximum period in seconds that this call will wait for communications with the dual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. (NOTE: Currently this option is only available for socket based component tunnels.)

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc \= ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.15 ESMF_CplCompSet - Set or reset information about the CplComp

INTERFACE:

    subroutine ESMF_CplCompSet(cplcomp, config, configfile,督 &
    clock, name, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(inout)       :: cplcomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Config), intent(in), optional :: config
    character(len=*) , intent(in), optional :: configfile
    type(ESMF_Clock),   intent(in), optional :: clock
    character(len=*)   , intent(in), optional :: name
    integer,           intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Sets or resets information about an ESMF_CplComp.

The arguments are:

**cplcomp**  ESMF_CplComp to change.

**[name]**  Set the name of the ESMF_CplComp.

**[config]**  Set the configuration information for the ESMF_CplComp from this already created ESMF_Config object. If specified, takes priority over configFile.

**[configFile]**  Set the configuration filename for this ESMF_CplComp. An ESMF_Config object will be created for this file and attached to the ESMF_CplComp. Superceeded by config if both are specified.

**[clock]**  Set the private clock for this ESMF_CplComp.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

17.4.16  ESMF_CplCompSetEntryPoint - Set user routine as entry point for standard Component method

INTERFACE:

```fortran
recursive subroutine ESMF_CplCompSetEntryPoint(cplcomp, methodflag, &
userRoutine, phase, rc)

ARGUMENTS:

  type(ESMF_CplComp), intent(inout) :: cplcomp
  type(ESMF_Method_Flag), intent(in) :: methodflag

interface
  subroutine userRoutine(cplcomp, importState, exportState, clock, rc)
    use ESMF_CompMod
    use ESMF_StateMod
    use ESMF_ClockMod
    implicit none
    type(ESMF_CplComp) :: cplcomp ! must not be optional
    type(ESMF_State) :: importState ! must not be optional
    type(ESMF_State) :: exportState ! must not be optional
    type(ESMF_Clock) :: clock ! must not be optional
    integer, intent(out) :: rc ! must not be optional
  end subroutine
end interface
```

**STATUS:**
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Registers a user-supplied userRoutine as the entry point for one of the predefined Component methodflag s. After this call the userRoutine becomes accessible via the standard Component method API.

The arguments are:

cplcomp  An ESMF_CplComp object.
methodflag One of a set of predefined Component methods - e.g., ESMF_METHOD_INITIALIZE, ESMF_METHOD_RUN, ESMF_METHOD_FINALIZE. See section 30.39 for a complete list of valid method options.
userRoutine The user-supplied subroutine to be associated for this methodflag. The Component writer must supply a subroutine with the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

[phase]  The phase number for multi-phase methods. For single phase methods the phase argument can be omitted. The default setting is 1.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

17.4.17 ESMF_CplCompSetInternalState - Set private data block pointer

INTERFACE:

subroutine ESMF_CplCompSetInternalState(cplcomp, wrappedDataPointer, rc)

ARGUMENTS:

type(ESMF_CplComp) :: cplcomp
type(wrapper) :: wrappedDataPointer
integer, intent(out) :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Available to be called by an ESMF_CplComp at any time, but expected to be most useful when called during the registration process, or initialization. Since init, run, and finalize must be separate subroutines data that they need to share in common can either be module global data, or can be allocated in a private data block and the address of that
block can be registered with the framework and retrieved by subsequent calls. When running multiple instantiations of an ESMF_CplComp, for example during ensemble runs, it may be simpler to maintain private data specific to each run with private data blocks. A corresponding ESMF_CplCompGetInternalState call retrieves the data pointer.

Only the last data block set via ESMF_CplCompSetInternalState will be accessible.

CAUTION: This method does not have an explicit Fortran interface. Do not specify argument keywords when calling this method!

The arguments are:

**cplcomp** An ESMF_CplComp object.

**wrappedDataPointer** A pointer to the private data block, wrapped in a derived type which contains only a pointer to the block. This level of indirection is needed to reliably set and retrieve the data block no matter which architecture or compiler is used.

**rc** Return code; equals ESMF_SUCCESS if there are no errors. Note: unlike most other ESMF routines, this argument is not optional because of implementation considerations.

---

### 17.4.18 ESMF_CplCompSetServices - Call user routine to register CplComp methods

**INTERFACE:**

```fortran
recursive subroutine ESMF_CplCompSetServices(cplcomp, userRoutine, &
userRc, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_CplComp), intent(inout) :: cplcomp
interface
  subroutine userRoutine(cplcomp, rc)
    use ESMF_CompMod
    implicit none
    type(ESMF_CplComp) :: cplcomp ! must not be optional
    integer, intent(out) :: rc ! must not be optional
  end subroutine
end interface
```

---

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Call into user provided **userRoutine** which is responsible for for setting Component’s Initialize(), Run(), and Finalize() services.

The arguments are:
cplcomp  Coupler Component.

userRoutine The Component writer must supply a subroutine with the exact interface shown above for the 
userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, 
intent and order must match. The subroutine must be either a module scope procedure, or an external procedure 
that has a matching interface block specified for it. It must not be an internal procedure which is contained 
within another procedure.

The userRoutine, when called by the framework, must make successive calls to 
ESMF_CplCompSetEntryPoint() to preset callback routines for standard Component Initialize(), 
Run(), and Finalize() methods.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.19 ESMF_CplCompSetServices - Call user routine through name lookup, to register CplComp methods

INTERFACE:

! Private name; call using ESMF_CplCompSetServices()
recursive subroutine ESMF_CplCompSetServicesShObj(cplcomp, userRoutine, & 
sharedObj, userRoutineFound, userRc, rc)

ARGUMENTS:

type(ESMF_CplComp), intent(inout) :: cplcomp
character(len=*) , intent(in) :: userRoutine
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len=*) , intent(in), optional :: sharedObj
logical, intent(out), optional :: userRoutineFound
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release. Changes made after the 5.2.0r release:

  6.3.0r Added argument userRoutineFound. The new argument provides a way to test availability without causing error conditions.

DESCRIPTION:
Call into a user provided routine which is responsible for setting Component’s Initialize(), Run(), and Finalize() services. The named userRoutine must exist in the executable, or in the shared object specified by sharedObj. In the latter case all of the platform specific details about dynamic linking and loading apply.

The arguments are:

**cplcomp**  Coupler Component.

**userRoutine**  Name of routine to be called, specified as a character string. The Component writer must supply a subroutine with the exact interface shown for userRoutine below. Arguments must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

**INTERFACE:**

```fortran
interface
    subroutine userRoutine(cplcomp, rc)
        type(ESMF_CplComp) :: cplcomp ! must not be optional
        integer, intent(out) :: rc ! must not be optional
    end subroutine
end interface
```

**DESCRIPTION:**

The userRoutine, when called by the framework, must make successive calls to ESMF_CplCompSetEntryPoint() to preset callback routines for standard Component Initialize(), Run(), and Finalize() methods.

**[sharedObj]**  Name of shared object that contains userRoutine. If the sharedObj argument is not provided the executable itself will be searched for userRoutine.

**[userRoutineFound]**  Report back whether the specified userRoutine was found and executed, or was not available. If this argument is present, not finding the userRoutine will not result in returning an error in rc. The default is to return an error if the userRoutine cannot be found.

**[userRc]**  Return code set by userRoutine before returning.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

17.4.20  ESMF_CplCompSetServices - Set to serve as Dual Component for an Actual Component

**INTERFACE:**

```fortran
! Private name; call using ESMF_CplCompSetServices()
recursive subroutine ESMF_CplCompSetServicesComp(cplcomp, &
    actualCplcomp, rc)
```

**ARGUMENTS:**
### 17.4.21 ESMF_CplCompSetServices - Set to serve as Dual Component for an Actual Component through sockets

**INTERFACE:**

```fortran
! Private name; call using ESMF_CplCompSetServices()
recursive subroutine ESMF_CplCompSetServicesSock(cplcomp, port, &
server, timeout, timeoutFlag, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_CplComp), intent(inout) :: cplcomp
integer, intent(in) :: port
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
classic(len=*), intent(in), optional :: server
integer, intent(in), optional :: timeout
logical, intent(out), optional :: timeoutFlag
integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Set the services of a Coupler Component to serve a "dual" Component for an "actual" Component. The component tunnel is socket based.

The arguments are:

- **cplcomp** Dual Coupler Component.
- **port** Port number under which the actual component is being served. The valid port range is [1024, 65535].
- **[server]** Server name where the actual component is being served. The default, i.e. if the *server* argument was not provided, is *localhost*. 

[timeout] The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour.

[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of rc $\leq$ ESMF_SUCCESS. Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.22 ESMF_CplCompSetVM - Call user routine to set CplComp VM properties

INTERFACE:

recursive subroutine ESMF_CplCompSetVM(cplcomp, userRoutine, & userRc, rc)

ARGUMENTS:

type(ESMF_CplComp), intent(inout) :: cplcomp  
interface  
  subroutine userRoutine(cplcomp, rc)  
    use ESMF_CompMod  
    implicit none  
    type(ESMF_CplComp) :: cplcomp ! must not be optional  
    integer, intent(out) :: rc ! must not be optional  
  end subroutine  
end interface  
-- The following arguments require argument keyword syntax (e.g. rc=rc). --  
integer, intent(out), optional :: userRc  
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Optionally call into user provided userRoutine which is responsible for setting Component’s VM properties. The arguments are:

cplcomp Coupler Component.

userRoutine The Component writer must supply a subroutine with the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

The subroutine, when called by the framework, is expected to use any of the ESMF_CplCompSetVMxxx() methods to set the properties of the VM associated with the Coupler Component.
[userRc] Return code set by userRoutine before returning.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.23 ESMF_CplCompSetVM - Call user routine through name lookup, to set CplComp VM properties

INTERFACE:

! Private name; call using ESMF_CplCompSetVM()
recursive subroutine ESMF_CplCompSetVMShObj(cplcomp, userRoutine, &
    sharedObj, userRc, rc)

ARGUMENTS:

type(ESMF_CplComp), intent(inout) :: cplcomp
character(len=*), intent(in) :: userRoutine
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len=*), intent(in), optional :: sharedObj
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Optionally call into user provided userRoutine which is responsible for setting Component’s VM properties. The named userRoutine must exist in the executable, or in the shared object specified by sharedObj. In the latter case all of the platform specific details about dynamic linking and loading apply.

The arguments are:

cplcomp Coupler Component.

userRoutine Routine to be called, specified as a character string. The Component writer must supply a subroutine with the exact interface shown for userRoutine below. Arguments must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

INTERFACE:

    interface
    subroutine userRoutine(cplcomp, rc)
        type(ESMF_CplComp) :: cplcomp ! must not be optional
        integer, intent(out) :: rc ! must not be optional
    end subroutine
    end interface
DESCRIPTION:

The subroutine, when called by the framework, is expected to use any of the ESMF_CplCompSetVMxxx() methods to set the properties of the VM associated with the Coupler Component.

[sharedObj] Name of shared object that contains userRoutine. If the sharedObj argument is not provided the executable itself will be searched for userRoutine.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.24 ESMF_CplCompSetVMMaxPEs - Associate PEs with PETs in CplComp VM

INTERFACE:

subroutine ESMF_CplCompSetVMMaxPEs(cplcomp, &
   maxPeCountPerPet, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)

ARGUMENTS:

type(ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: maxPeCountPerPet
integer, intent(in), optional :: prefIntraProcess
integer, intent(in), optional :: prefIntraSsi
integer, intent(in), optional :: prefInterSsi
integer, intent(out), optional :: rc

DESCRIPTION:

Set characteristics of the ESMF_VM for this ESMF_CplComp. Attempts to associate up to maxPeCountPerPet PEs with each PET. Only PEs that are located on the same single system image (SSI) can be associated with the same PET. Within this constraint the call tries to get as close as possible to the number specified by maxPeCountPerPet.

The other constraint to this call is that the number of PEs is preserved. This means that the child Component in the end is associated with as many PEs as the parent Component provided to the child. The number of child PETs however is adjusted according to the above rule.

The typical use of ESMF_CplCompSetVMMaxPEs() is to allocate multiple PEs per PET in a Component for user-level threading, e.g. OpenMP.

The arguments are:

cplcomp ESMF_CplComp to set the ESMF_VM for.

[maxPeCountPerPet] Maximum number of PEs on each PET. Default for each SSI is the local number of PEs.

[prefIntraSsi] Communication preference within a single system image (SSI). *Currently options not documented.* Use default.

[prefInterSsi] Communication preference between different single system images (SSIs). *Currently options not documented.* Use default.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

17.4.25 ESMF_CplCompSetVMMaxThreads - Set multi-threaded PETs in CplComp VM

INTERFACE:

```fortran
subroutine ESMF_CplCompSetVMMaxThreads(cplcomp, 
   maxPetCountPerVas, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)
```

ARGUMENTS:

```fortran
type(ESMF_CplComp), intent(inout) :: cplcomp
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer, intent(in), optional :: maxPetCountPerVas
   integer, intent(in), optional :: prefIntraProcess
   integer, intent(in), optional :: prefIntraSsi
   integer, intent(in), optional :: prefInterSsi
   integer, intent(out), optional :: rc
```

DESCRIPTION:

Set characteristics of the ESMF_VM for this ESMF_CplComp. Attempts to provide maxPetCountPerVas threaded PETs in each virtual address space (VAS). Only as many threaded PETs as there are PEs located on the single system image (SSI) can be associated with the VAS. Within this constraint the call tries to get as close as possible to the number specified by maxPetCountPerVas.

The other constraint to this call is that the number of PETs is preserved. This means that the child Component in the end is associated with as many PETs as the parent Component provided to the child. The threading level of the child PETs however is adjusted according to the above rule.

The typical use of ESMF_CplCompSetVMMaxThreads() is to run a Component multi-threaded with groups of PETs executing within a common virtual address space.

The arguments are:

- **cplcomp** ESMF_CplComp to set the ESMF_VM for.
- **[maxPetCountPerVas]** Maximum number of threaded PETs in each virtual address space (VAS). Default for each SSI is the local number of PEs.
- **[prefIntraSsi]** Communication preference within a single system image (SSI). *Currently options not documented.* Use default.
[prefInterSsi] Communication preference between different single system images (SSIs). *Currently options not documented. Use default.*

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

### 17.4.26 ESMF_CplCompSetVMMinThreads - Set a reduced threading level in CplComp VM

**INTERFACE:**

```fortran
subroutine ESMF_CplCompSetVMMinThreads(cplcomp, &
  maxPeCountPerPet, prefIntraProcess, prefIntraSsi, prefInterSsi, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_CplComp), intent(inout) :: cplcomp
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: maxPeCountPerPet
  integer, intent(in), optional :: prefIntraProcess
  integer, intent(in), optional :: prefIntraSsi
  integer, intent(in), optional :: prefInterSsi
  integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Set characteristics of the ESMF_VM for this ESMF_CplComp. Reduces the number of threaded PETs in each VAS. The `max` argument may be specified to limit the maximum number of PEs that a single PET can be associated with.

Several constraints apply: 1) the number of PEs cannot change, 2) PEs cannot migrate between single system images (SSIs), 3) the number of PETs cannot increase, only decrease, 4) PETs cannot migrate between virtual address spaces (VASs), nor can VASs migrate between SSIs.

The typical use of ESMF_CplCompSetVMMinThreads() is to run a Component across a set of single-threaded PETs.

The arguments are:

- **cplcomp** ESMF_CplComp to set the ESMF_VM for.
- **[maxPeCountPerPet]** Maximum number of PEs on each PET. Default for each SSI is the local number of PEs.
- **[prefIntraSsi]** Communication preference within a single system image (SSI). *Currently options not documented. Use default.*
- **[prefInterSsi]** Communication preference between different single system images (SSIs). *Currently options not documented. Use default.*
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
17.4.27 ESMF_CplCompValidate – Ensure the CplComp is internally consistent

INTERFACE:

    subroutine ESMF_CplCompValidate(cplcomp, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(in) :: cplcomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Currently all this method does is to check that the cplcomp was created.

The arguments are:

  cplcomp  ESMF_CplComp to validate.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

17.4.28 ESMF_CplCompWait - Wait for a CplComp to return

INTERFACE:

    subroutine ESMF_CplCompWait(cplcomp, syncflag, &
                                 timeout, timeoutFlag, userRc, rc)

ARGUMENTS:

    type(ESMF_CplComp), intent(inout) :: cplcomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Sync_Flag), intent(in), optional :: syncflag
    integer, intent(in), optional :: timeout
    logical, intent(out), optional :: timeoutFlag
    integer, intent(out), optional :: userRc
    integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

**5.3.0** Added argument `timeout`. Added argument `timeoutFlag`. The new arguments provide access to the fault-tolerant component features.

**DESCRIPTION:**

When executing asynchronously, wait for an ESMF_CplComp to return.

The arguments are:

- `cplcomp` ESMF_CplComp to wait for.

- `[syncflag]` Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is `ESMF_SYNC_VASBLOCKING` which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

- `[timeout]` The maximum period in seconds the actual component is allowed to execute a previously invoked component method before it must communicate back to the dual component. If the actual component does not communicate back in the specified time, a timeout condition is raised on the dual side (this side). The default is 3600, i.e. 1 hour. The `timeout` argument is only supported for connected dual components.

- `[timeoutFlag]` Returns `true` if the timeout was reached, `false` otherwise. If `timeoutFlag` was not provided, a timeout condition will lead to a return code of `rc \= ESMF_SUCCESS`. Otherwise the return value of `timeoutFlag` is the sole indicator of a timeout condition.

- `[userRc]` Return code set by `userRoutine` before returning.

- `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.

---

**17.4.29 ESMF_CplCompWriteRestart – Call the CplComp’s write restart routine**

**INTERFACE:**

```fortran
recursive subroutine ESMF_CplCompWriteRestart(cplcomp, &
   importState, exportState, clock, syncflag, phase, timeout, timeoutFlag, &
   userRc, rc)
```

**ARGUMENTS:**

- `type (ESMF_CplComp), intent (inout) :: cplcomp`
- `type (ESMF_State), intent (inout), optional :: importState`
- `type (ESMF_State), intent (inout), optional :: exportState`
type (ESMF_Clock), intent(inout), optional :: clock

type (ESMF_Sync_Flag), intent(in), optional :: syncflag

integer, intent(in), optional :: phase

integer, intent(in), optional :: timeout

logical, intent(out), optional :: timeoutFlag

integer, intent(out), optional :: userRc

integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added argument timeout. Added argument timeoutFlag. The new arguments provide access to the fault-tolerant component features.

DESCRIPTION:

Call the associated user write restart routine for an ESMF_CplComp.

The arguments are:

**cplcomp** ESMF_CplComp to call run routine for.

**[importState]** ESMF_State containing import data. If not present, a dummy argument will be passed to the user-supplied routine. The importState argument in the user code cannot be optional.

**[exportState]** ESMF_State containing export data. If not present, a dummy argument will be passed to the user-supplied routine. The exportState argument in the user code cannot be optional.

**[clock]** External ESMF_Clock for passing in time information. This is generally the parent component’s clock, and will be treated as read-only by the child component. The child component can maintain a private clock for its own internal time computations. If not present, a dummy argument will be passed to the user-supplied routine. The clock argument in the user code cannot be optional.

**[syncflag]** Blocking behavior of this method call. See section 50.50 for a list of valid blocking options. Default option is ESMF_SYNC_VASBLOCKING which blocks PETs and their spawned off threads across each VAS but does not synchronize PETs that run in different VASs.

**[phase]** Component providers must document whether their each of their routines are *single-phase* or *multi-phase*. Single-phase routines require only one invocation to complete their work. Multi-phase routines provide multiple subroutines to accomplish the work, accommodating components which must complete part of their work, return to the caller and allow other processing to occur, and then continue the original operation. For multiple-phase child components, this is the integer phase number to be invoked. For single-phase child components this argument is optional. The default is 1.

**[timeout]** The maximum period in seconds that this call will wait in communications with the actual component, before returning with a timeout condition. The default is 3600, i.e. 1 hour. The timeout argument is only supported for connected dual components.
[timeoutFlag] Returns .true. if the timeout was reached, .false. otherwise. If timeoutFlag was not provided, a timeout condition will lead to a return code of \( rc \neq \text{ESMF\_SUCCESS} \). Otherwise the return value of timeoutFlag is the sole indicator of a timeout condition.

[userRc] Return code set by userRoutine before returning.

[rc] Return code; equals ESMF\_SUCCESS if there are no errors.

18 SciComp Class

18.1 Description

In Earth system modeling, a particular piece of code representing a physical domain, such as an atmospheric model or an ocean model, is typically implemented as an ESMF Gridded Component, or ESMC\_GridComp. However, there are times when physical domains, or realms, need to be represented, but aren’t actual pieces of code, or software. These domains can be implemented as ESMF Science Components, or ESMC\_SciComp.

Unlike Gridded and Coupler Components, Science Components are not associated with software; they don’t include execution routines such as initialize, run and finalize. The main purpose of a Science Component is to provide a container for Attributes within a Component hierarchy.

18.2 Use and Examples

A Science Component is a container object intended to represent scientific domains, or realms, in an Earth Science Model. It’s primary purpose is to provide a means for representing Component metadata within a hierarchy of Components, and it does this by being a container for Attributes as well as other Components.

18.2.1 Use ESMF\_SciComp and Attach Attributes

This example illustrates the use of the ESMF\_SciComp to attach Attributes within a Component hierarchy. The hierarchy includes Coupler, Gridded, and Science Components and Attributes are attached to the Science Components. For demonstrable purposes, we’ll add some CIM Component attributes to the Gridded Component. However, for a complete example of the CIM Attribute packages supplied by ESMF, see the example in the ESMF Attributes section.

Create the top 2 levels of the Component hierarchy. This example creates a parent Coupler Component and 2 Gridded Components as children.

```fortran
! Create top-level Coupler Component
cplcomp = ESMF_CplCompCreate(name="coupler_component", rc=rc)

! Create Gridded Component for Atmosphere
atmcomp = ESMF_GridCompCreate(name="Atmosphere", rc=rc)

! Create Gridded Component for Ocean
ocncomp = ESMF_GridCompCreate(name="Ocean", rc=rc)

! Link the attributes for the parent and child components
call ESMF_AttributeLink(cplcomp, atmcomp, rc=rc)  
call ESMF_AttributeLink(cplcomp, ocncomp, rc=rc)
```

153
Now add CIM Attribute packages to the Component. Also, add a CIM Component Properties package, to contain two custom attributes.

```plaintext
convCIM = 'CIM 1.5'
purpComp = 'ModelComp'
purpProp = 'CompProp'
purpField = 'Inputs'
purpPlatform = 'Platform'

convISO = 'ISO 19115'
purpRP = 'RespParty'
purpCitation = 'Citation'

! Add CIM Attribute package to the Science Component
call ESMF_AttributeAdd(atmcomp, convention=convCIM, &
    purpose=purpComp, rc=rc)
```

Now, add some CIM Component attributes to the Atmosphere Grid Component.

```plaintext
!
! Top-level model component attributes, set on gridded component!
call ESMF_AttributeSet(atmcomp, 'ShortName', 'EarthSys_Atmos', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(atmcomp, 'LongName', &
    'Earth System High Resolution Global Atmosphere Model', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(atmcomp, 'Description', &
    'EarthSys brings together expertise from the global ' &
    'community in a concerted effort to develop coupled ' &
    'climate models with increased horizontal resolutions. ' &
    'Increasing the horizontal resolution of coupled climate ' &
    'models will allow us to capture climate processes and ' &
    'weather systems in much greater detail.', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(atmcomp, 'Version', '2.0', &
    convention=convCIM, purpose=purpComp, rc=rc)
```
call ESMF_AttributeSet(atmcomp, 'ReleaseDate', '2009-01-01T00:00:00Z', &
convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(atmcomp, 'ModelType', 'aerosol', &
convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(atmcomp, 'URL', &
'www.earthsys.org', convention=convCIM, purpose=purpComp, rc=rc)

Now create a set of Science Components as a children of the Atmosphere Gridded Component. The hierarchy is as follows:

- Atmosphere
  - AtmosDynamicalCore
    - AtmosAdvection
  - Atmos Radiation

After each Component is created, we need to link it with its parent Component. We then add some standard CIM Component properties as well as Scientific Properties to each of these components.

```c
! Atmosphere Dynamical Core Science Component
!
dc_scicomp = ESMF_SciCompCreate(name="AtmosDynamicalCore", rc=rc)

call ESMF_AttributeLink(atmcomp, dc_scicomp, rc=rc)

call ESMF_AttributeAdd(dc_scicomp, &
convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(dc_scicomp, "ShortName", "AtmosDynamicalCore", &
convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(dc_scicomp, "LongName", &
"Atmosphere Dynamical Core", &
convention=convCIM, purpose=purpComp, rc=rc)

purpSci = 'SciProp'
dc_scipropAtt(1) = 'TopBoundaryCondition'
dc_scipropAtt(2) = 'HeatTreatmentAtTop'
dc_scipropAtt(3) = 'WindTreatmentAtTop'
```
call ESMF_AttributeAdd(dc_scicomp, 
         convention=convCIM, purpose=purpSci, 
         attrList=dc_sciPropAtt, rc=rc)

call ESMF_AttributeGetAttPack(dc_scicomp, convCIM, purpSci, attpack=attpack, rc=rc)

call ESMF_AttributeSet(dc_scicomp, 'TopBoundaryCondition', 
         'radiation boundary condition', 
         convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeSet(dc_scicomp, 'HeatTreatmentAtTop', 
         'some heat treatment', 
         convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeSet(dc_scicomp, 'WindTreatmentAtTop', 
         'some wind treatment', 
         convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeAdd(adv_scicomp, 
         convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(adv_scicomp, 'ShortName', "AtmosAdvection", 
         convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(adv_scicomp, 'LongName', "Atmosphere Advection", 
         convention=convCIM, purpose=purpComp, rc=rc)

adv_sciPropAtt(1) = 'TracersSchemeName'
adv_sciPropAtt(2) = 'TracersSchemeCharacteristics'
adv_sciPropAtt(3) = 'MomentumSchemeName'

call ESMF_AttributeAdd(adv_scicomp, 
         convention=convCIM, purpose=purpSci, 
         attrList=adv_sciPropAtt, rc=rc)

call ESMF_AttributeSet(adv_scicomp, 'TracersSchemeName', 'Prather', 
         convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeSet(adv_scicomp, 'TracersSchemeCharacteristics', 
         'modified Euler', 
         convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeSet(adv_scicomp, 'MomentumSchemeName', 'Van Leer', 
         convention=convCIM, purpose=purpSci, rc=rc)

!
! Atmosphere Radiation Science Component

rad_scicomp = ESMF_SciCompCreate(name="AtmosRadiation", rc=rc)

call ESMF_AttributeLink(atmcomp, rad_scicomp, rc=rc)

call ESMF_AttributeAdd(rad_scicomp, &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(rad_scicomp, "ShortName", "AtmosRadiation", &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(rad_scicomp, "LongName", &
    "Atmosphere Radiation", &
    convention=convCIM, purpose=purpComp, rc=rc)

rad_sciPropAtt(1) = 'LongwaveSchemeType'
rad_sciPropAtt(2) = 'LongwaveSchemeMethod'

call ESMF_AttributeAdd(rad_scicomp, &
    convention=convCIM, purpose=purpSci, &
    attrList=rad_sciPropAtt, rc=rc)

call ESMF_AttributeSet(rad_scicomp, &
    'LongwaveSchemeType', &
    'wide-band model', &
    convention=convCIM, purpose=purpSci, rc=rc)

call ESMF_AttributeSet(rad_scicomp, &
    'LongwaveSchemeMethod', &
    'two-stream', &
    convention=convCIM, purpose=purpSci, rc=rc)

Write the entire CIM Attribute hierarchy, beginning at the top of the Component hierarchy (the Coupler Component), to an XML file formatted to conform to CIM specifications. The file is written to the examples execution directory.

call ESMF_AttributeWrite(cplcomp, convCIM, purpComp, &
    attwriteflag=ESMF_ATTWRITE_XML,rc=rc)

Finally, destroy all of the Components.

call ESMF_SciCompDestroy(rad_scicomp, rc=rc)
call ESMF_SciCompDestroy(adv_scicomp, rc=rc)
call ESMF_SciCompDestroy(dc_scicomp, rc=rc)
call ESMF_GridCompDestroy(atmcomp, rc=rc)
call ESMF_GridCompDestroy(ocncomp, rc=rc)
call ESMF_CplCompDestroy(cplcomp, rc=rc)
18.3 Restrictions and Future Work

1. None.

18.4 Class API

18.4.1 ESMF_SciCompAssignment(=) - SciComp assignment

INTERFACE:

interface assignment (=)
scicomp1 = scicomp2

ARGUMENTS:

type(ESMF_SciComp) :: scicomp1
type(ESMF_SciComp) :: scicomp2

DESCRIPTION:

Assign scicomp1 as an alias to the same ESMF SciComp object in memory as scicomp2. If scicomp2 is invalid, then scicomp1 will be equally invalid after the assignment.

The arguments are:

scicomp1 The ESMF_SciComp object on the left hand side of the assignment.
scicomp2 The ESMF_SciComp object on the right hand side of the assignment.

18.4.2 ESMF_SciCompOperator(==) - SciComp equality operator

INTERFACE:

interface operator (==)
if (scicomp1 == scicomp2) then ... endif
OR
result = (scicomp1 == scicomp2)

RETURN VALUE:

logical :: result

ARGUMENTS:

type(ESMF_SciComp), intent(in) :: scicomp1
type(ESMF_SciComp), intent(in) :: scicomp2
DESCRIPTION:

Test whether scicomp1 and scicomp2 are valid aliases to the same ESMF SciComp object in memory. For a more general comparison of two ESMF SciComps, going beyond the simple alias test, the ESMF_SciCompMatch() function (not yet implemented) must be used.

The arguments are:

scicomp1  The ESMF_SciComp object on the left hand side of the equality operation.
scicomp2  The ESMF_SciComp object on the right hand side of the equality operation.

18.4.3  ESMF_SciCompOperator(/=) - SciComp not equal operator

INTERFACE:

    interface operator(/=)
        if (scicomp1 /= scicomp2) then ... endif
    OR
        result = (scicomp1 /= scicomp2)
    endif

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_SciComp), intent(in) :: scicomp1
    type(ESMF_SciComp), intent(in) :: scicomp2

DESCRIPTION:

Test whether scicomp1 and scicomp2 are not valid aliases to the same ESMF SciComp object in memory. For a more general comparison of two ESMF SciComps, going beyond the simple alias test, the ESMF_SciCompMatch() function (not yet implemented) must be used.

The arguments are:

scicomp1  The ESMF_SciComp object on the left hand side of the non-equality operation.
scicomp2  The ESMF_SciComp object on the right hand side of the non-equality operation.

18.4.4  ESMF_SciCompCreate - Create a SciComp

INTERFACE:
recursive function ESMF_SciCompCreate(name, rc)

RETURN VALUE:

type(ESMF_SciComp) :: ESMF_SciCompCreate

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len=*),     intent(in),   optional :: name
integer,              intent(out),  optional :: rc

DESCRIPTION:

This interface creates an ESMF_SciComp object. The return value is the new ESMF_SciComp.

The arguments are:

[name] Name of the newly-created ESMF_SciComp. This name can be altered from within the ESMF_SciComp code once the initialization routine is called.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

18.4.5 ESMF_SciCompDestroy - Release resources associated with a SciComp

INTERFACE:

subroutine ESMF_SciCompDestroy(scicomp, rc)

ARGUMENTS:

    type(ESMF_SciComp), intent(inout) :: scicomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer,                         intent(out),  optional :: rc

DESCRIPTION:

Destroys an ESMF_SciComp, releasing the resources associated with the object.

The arguments are:

scicomp Release all resources associated with this ESMF_SciComp and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
18.4.6 ESMF_SciCompGet - Get SciComp information

INTERFACE:

subroutine ESMF_SciCompGet(scicomp, name, rc)

ARGUMENTS:

  type(ESMF_SciComp), intent(in) :: scicomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  character(len=*) , intent(out), optional :: name
  integer,           intent(out), optional :: rc

DESCRIPTION:

Get information about an ESMF_SciComp object.

The arguments are:

scicomp  The ESMF_SciComp object being queried.
[name]  Return the name of the ESMF_SciComp.
[rc]     Return code; equals ESMF_SUCCESS if there are no errors.

____________________________

18.4.7 ESMF_SciCompPrint - Print SciComp information

INTERFACE:

subroutine ESMF_SciCompPrint(scicomp, rc)

ARGUMENTS:

  type(ESMF_SciComp), intent(in) :: scicomp
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer,           intent(out), optional :: rc

DESCRIPTION:

Prints information about an ESMF_SciComp to stdout.

The arguments are:

scicomp  ESMF_SciComp to print.
[rc]     Return code; equals ESMF_SUCCESS if there are no errors.

____________________________
18.4.8 ESMF_SciCompSet - Set or reset information about the SciComp

INTERFACE:

    subroutine ESMF_SciCompSet(scicomp, name, rc)

ARGUMENTS:

    type(ESMF_SciComp), intent(inout) :: scicomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(len=*) , intent(in), optional :: name
    integer, intent(out), optional :: rc

DESCRIPTION:

Sets or resets information about an ESMF_SciComp.

The arguments are:

scicomp  ESMF_SciComp to change.
[name]  Set the name of the ESMF_SciComp.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

18.4.9 ESMF_SciCompValidate - Check validity of a SciComp

INTERFACE:

    subroutine ESMF_SciCompValidate(scicomp, rc)

ARGUMENTS:

    type(ESMF_SciComp), intent(in) :: scicomp
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

DESCRIPTION:

Currently all this method does is to check that the scicomp was created.

The arguments are:

scicomp  ESMF_SciComp to validate.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
19 Fault-tolerant Component Tunnel

19.1 Description

For ensemble runs with many ensemble members, fault-tolerance becomes an issue of very critical practical impact. The meaning of fault-tolerance in this context refers to the ability of an ensemble application to continue with normal execution after one or more ensemble members have experienced catastrophic conditions, from which they cannot recover. ESMF implements this type of fault-tolerance on the Component level via a timeout paradigm: A timeout parameter is specified for all interactions that need to be fault-tolerant. When a connection to a component times out, maybe because it has become inaccessible due to some catastrophic condition, the driver application can react to this condition, for example by not further interacting with the component during the otherwise normal continuation of the model execution.

The fault-tolerant connection between a driver application and a Component is established through a Component Tunnel. There are two sides to a Component Tunnel: the "actual" side is where the component is actually executing, and the "dual" side is the portal through which the Component becomes accessible on the driver side. Both the actual and the dual side of a Component Tunnel are implemented in form of a regular ESMF Gridded or Coupler Component.

Component Tunnels between Components can be based on a number of low level implementations. The only implementation that currently provides fault-tolerance is socket based. In this case an actual Component typically runs as a separate executable, listening to a specific port for connections from the driver application. The dual Component is created on the driver side. It connects to the actual Component during the SetServices() call.

19.2 Use and Examples

A Component Tunnel connects a dual Component to an actual Component. This connection can be based on a number of different low level implementations, e.g. VM-based or socket-based. VM-based Component Tunnels require that both dual and actual Components run within the same application (i.e. execute under the same MPI_COMM_WORLD). Fault-tolerant Component Tunnels require that dual and actual Components run in separate applications, under different MPI_COMM_WORLD communicators. This mode is implemented in the socket-based Component Tunnels.

19.2.1 Creating an actual Component

The creation process of an actual Gridded Component, which will become one of the two end points of a Component Tunnel, is identical to the creation of a regular Gridded Component. On the actual side, an actual Component is very similar to a regular Component. Here the actual Component is created with a custom petList.

```python
petList = (/0,1,2/)
actualComp = ESMF_GridCompCreate(petList=petList, name="actual", rc=rc)
```

19.2.2 Creating a dual Component

The same way an actual Component appears as a regular Component in the context of the actual side application, a dual Component is created as a regular Component on the dual side. A dual Gridded Component with custom petList is created using the regular create call.

```python
petList = (/4,3,5/)
```
dualComp = ESMF_GridCompCreate(petList=petList, name="dual", rc=rc)

19.2.3 Setting up the actual side of a Component Tunnel

After creation, the regular procedure for registering the standard Component methods is followed for the actual Gridded Component.

call ESMF_GridCompSetServices(actualComp, userRoutine=setservices, &
userRc=userRc, rc=rc)

So far the actualComp object is no different from a regular Gridded Component. In order to turn it into the actual end point of a Component Tunnel the ServiceLoop() method is called. Here the socket-based implementation is chosen.

call ESMF_GridCompServiceLoop(actualComp, port=61010, timeout=20, rc=rc)

This call opens the actual side of the Component Tunnel in form of a socket-based server, listening on port 61010. The timeout argument specifies how long the actual side will wait for the dual side to connect, before the actual side returns with a time out condition. The time out is set to 20 seconds.

At this point, before a dual Component connects to the other side of the Component Tunnel, it is possible to manually connect to the waiting actual Component. This can be useful when debugging connection issues. A convenient tool for this is the standard telnet application. Below is a transcript of such a connection. The manually typed commands are separate from the previous responses by a blank line.

$ telnet localhost 61010
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
Hello from ESMF Actual Component server!
date
Tue Apr 3 21:53:03 2012
version
ESMF_VERSION_STRING: 5.3.0

If at any point the telnet session is manually shut down, the ServiceLoop() on the actual side will return with an error condition. The clean way to disconnect the telnet session, and to have the ServiceLoop() wait for a new connection, e.g. from a dual Component, is to send the reconnect command. This will automatically shut down the telnet connection.

reconnect
Actual Component server will reconnect now!
Connection closed by foreign host.
$
At this point the actual Component is back in listening mode, with a time out of 20 seconds, as specified during the ServiceLoop() call.

Before moving on to the dual side of the GridComp based Component Tunnel example, it should be pointed out that the exact same procedure is used to set up the actual side of a CplComp based Component Tunnel. Assuming that actualCplComp is a CplComp object for which SetServices has already been called, the actual side uses ESMF_CplCompServiceLoop() to start listening for connections from the dual side.

```c
    call ESMF_CplCompServiceLoop(actualCplComp, port=61011, timeout=2, &
                              timeoutFlag=timeoutFlag, rc=rc)
```

Here the timeoutFlag is specified in order to prevent the expected time-out condition to be indicated through the return code. Instead, when timeoutFlag is present, the return code is still ESMF_SUCCESS, but timeoutFlag is set to .true. when a time-out occurs.

### 19.2.4 Setting up the dual side of a Component Tunnel

On the dual side, the dualComp object needs to be connected to the actual Component in order to complete the Component Tunnel. Instead of registering standard Component methods locally, a special variant of the SetServices() call is used to connect to the actual Component.

```c
    call ESMF_GridCompSetServices(dualComp, port=61010, server="localhost", &
                              timeout=10, timeoutFlag=timeoutFlag, rc=rc)
```

The port and server arguments are used to connect to the desired actual Component. The time out of 10 seconds ensures that if the actual Component is not available, a time out condition is returned instead of resulting in a hang. The timeoutFlag argument further absorbs the time out condition, either returning as .true. or .false.. In this mode the standard rc will indicate success even when a time out condition was reached.

### 19.2.5 Invoking standard Component methods through a Component Tunnel

Once a Component Tunnel is established, the actual Component is fully under the control of the dual Component. A standard Component method invoked on the dual Component is not executed by the dual Component itself, but by the actual Component instead. In fact, it is the entry points registered with the actual Component that are executed when standard methods are invoked on the dual Component. The connected dualComp object serves as a portal through which the connected actualComp becomes accessible on the dual side.

Typically the first standard method called is the CompInitialize() routine.

```c
    call ESMF_GridCompInitialize(dualComp, timeout=10, timeoutFlag=timeoutFlag, &
                              userRc=userRc, rc=rc)
```

Again, the timeout argument serves to prevent the dual side from hanging if the actual Component application has experienced a catastrophic condition and is no longer available, or takes longer than expected. The presence of the timeoutFlag allows time out conditions to be caught gracefully, so the dual side can deal with it in an orderly fashion, instead of triggering an application abort due to an error condition.

The CompRun() and CompFinalize() methods follow the same format.
call ESMF_GridCompRun(dualComp, timeout=10, timeoutFlag=timeoutFlag, &
userRc=userRc, rc=rc)

call ESMF_GridCompFinalize(dualComp, timeout=10, timeoutFlag=timeoutFlag, &
userRc=userRc, rc=rc)

19.2.6 The non-blocking option to invoke standard Component methods through a Component Tunnel

Standard Component methods called on a connected dual Component are executed on the actual side, across the
PETs of the actual Component. By default the dual Component PETs are blocked until the actual Component has
finished executing the invoked Component method, or until a time out condition has been reached. In many practical
applications a more loose synchronization between dual and actual Components is useful. Having the PETs of a dual
Component return immediately from a standard Component method allows multiple dual Component, on the same
PETs, to control multiple actual Components. If the actual Components are executing in separate executables, or
the same executable but on exclusive sets of PETs, they can execute concurrently, even with the controlling dual
Components all running on the same PETs. The non-blocking dual side regains control over the actual Component by
synchronizing through the CompWait() call.

Any of the standard Component methods can be called in non-blocking mode by setting the optional syncflag
argument to ESMF_SYNC_NONBLOCKING.

call ESMF_GridCompInitialize(dualComp, syncflag=ESMF_SYNC_NONBLOCKING, rc=rc)

If communication between the dual and the actual Component was successful, this call will return immediately on
all of the dual Component PETs, while the actual Component continues to execute the invoked Component method.
However, if the dual Component has difficulties reaching the actual Component, the call will block on all dual PETs
until successful contact was made, or the default time out (3600 seconds, i.e. 1 hour) has been reached. In most cases
a shorter time out condition is desired with the non-blocking option, as shown below.

First the dual Component must wait for the outstanding method.

call ESMF_GridCompWait(dualComp, rc=rc)

Now the same non-blocking CompInitialize() call is issued again, but this time with an explicit 10 second time out.

call ESMF_GridCompInitialize(dualComp, syncflag=ESMF_SYNC_NONBLOCKING, &
timeout=10, timeoutFlag=timeoutFlag, rc=rc)

This call is guaranteed to return within 10 seconds, or less, on the dual Component PETs, either without time out
condition, indicating that the actual Component has been contacted successfully, or with time out condition, indicating
that the actual Component was unreachable at the time. Either way, the dual Component PETs are back under user
control quickly.

Calling the CompWait() method on the dual Component causes the dual Component PETs to block until the actual
Component method has returned, or a time out condition has been reached.

call ESMF_GridCompWait(dualComp, userRc=userRc, rc=rc)
The default time out for CompWait() is 3600 seconds, i.e. 1 hour, just like for the other Component methods. However, the semantics of a time out condition under CompWait() is different from the other Component methods. Typically the timeout is simply the maximum time that any communication between dual and actual Component is allowed to take before a time out condition is raised. For CompWait(), the timeout is the maximum time that an actual Component is allowed to execute before reporting back to the dual Component. Here, even with the default time out, the dual Component would return from CompWait() immediately with a time out condition if the actual Component has already been executing for over 1 hour, and is not already waiting to report back when the dual Component calls CompWait(). On the other hand, if it has only been 30 minutes since ComplInitialize() was called on the dual Component, then the actual Component still has 30 minutes before CompWait() returns with a time out condition. During this time (or until the actual Component returns) the dual Component PETs are blocked.

A standard Component method is invoked in non-blocking mode.

```
call ESMF_GridCompRun(dualComp, syncflag=ESMF_SYNC_NONBLOCKING, &
timeout=10, timeoutFlag=timeoutFlag, rc=rc)
```

Once the user code on the dual side is ready to regain control over the actual Component it calls CompWait() on the dual Component. Here a timeout of 60s is specified, meaning that the total execution time the actual Component spends in the registered Run() routine may not exceed 60s before CompWait() returns with a time out condition.

```
call ESMF_GridCompWait(dualComp, timeout=60, userRc=userRc, rc=rc)
```

### 19.2.7 Destroying a connected dual Component

A dual Component that is connected to an actual Component through a Component Tunnel is destroyed the same way a regular Component is. The only difference is that a connected dual Component may specify a timeout argument to the CompDestroy() call.

```
call ESMF_GridCompDestroy(dualComp, timeout=10, rc=rc)
```

The timeout argument again ensures that the dual side does not hang indefinitely in case the actual Component has become unavailable. If the actual Component is available, the destroy call will indicate to the actual Component that it should break out of the ServiceLoop(). Either way, the local dual Component is destroyed.

### 19.2.8 Destroying a connected actual Component

An actual Component that is in a ServiceLoop() must first return from that call before it can be destroyed. This can either happen when a connected dual Component calls its CompDestroy() method, or if the ServiceLoop() reaches the specified time out condition. Either way, once control has been returned to the user code, the actual Component is destroyed in the same way a regular Component is, by calling the destroy method.

```
call ESMF_GridCompDestroy(actualComp, rc=rc)
```

### 19.3 Restrictions and Future Work

1. **No data flow through States.** The current implementation does not support data flow (Fields, FieldBundles, etc.) between actual and dual Components. The current work-around is to employ user controlled, file based
transfer methods. The next implementation phase will offer transparent data flow through the Component Tunnel, where the user code interacts with the States on the actual and dual side in the same way as if they were the same Component.

20 State Class

20.1 Description

A State contains the data and metadata to be transferred between ESMF Components. It is an important class, because it defines a standard for how data is represented in data transfers between Earth science components. The State construct is a rational compromise between a fully prescribed interface - one that would dictate what specific fields should be transferred between components - and an interface in which data structures are completely ad hoc.

There are two types of States, import and export. An import State contains data that is necessary for a Gridded Component or Coupler Component to execute, and an export State contains the data that a Gridded Component or Coupler Component can make available.

States can contain Arrays, ArrayBundles, Fields, FieldBundles, and other States. They cannot directly contain native language arrays (i.e. Fortran or C style arrays). Objects in a State must span the VM on which they are running. For sequentially executing components which run on the same set of PETs this happens by calling the object create methods on each PET, creating the object in unison. For concurrently executing components which are running on subsets of PETs, an additional method, called ESMF_StateReconcile(), is provided by ESMF to broadcast information about objects which were created in sub-components.

State methods include creation and deletion, adding and retrieving data items, adding and retrieving attributes, and performing queries.

20.2 Constants

20.2.1 ESMF_STATEINTENT

DESCRIPTION: Specifies whether a ESMF_State contains data to be imported into a component or exported from a component.

The type of this flag is:

\[
\text{type} \left( \text{ESMF\_StateIntent\_Flag} \right)
\]

The valid values are:

ESMF_STATEINTENT_IMPORT Contains data to be imported into a component.

ESMF_STATEINTENTEXPORT Contains data to be exported out of a component.

ESMF_STATEINTENT_UNSPECIFIED The intent has not been specified.

20.2.2 ESMF_STATEITEM

DESCRIPTION: Specifies the type of object being added to or retrieved from an ESMF_State.
The type of this flag is:

type(ESMF_StateItem_Flag)

The valid values are:

ESMF_STATEITEM_ARRAY Refers to an ESMF_Array within an ESMF_State.
ESMF_STATEITEM_ARRAYBUNDLE Refers to an ESMF_Array within an ESMF_State.
ESMF_STATEITEM_FIELD Refers to an ESMF_Field within an ESMF_State.
ESMF_STATEITEM_FIELDBUNDLE Refers to an ESMF_FieldBundle within an ESMF_State.
ESMF_STATEITEM_ROUTEHANDLE Refers to an ESMF_RouteHandle within an ESMF_State.
ESMF_STATEITEM_STATE Refers to an ESMF_State within an ESMF_State.

20.3 Use and Examples

A Gridded Component generally has one associated import State and one export State. Generally the States associated with a Gridded Component will be created by the Gridded Component’s parent component. In many cases, the States will be created containing no data. Both the empty States and the newly created Gridded Component are passed by the parent component into the Gridded Component’s initialize method. This is where the States get prepared for use and the import State is first filled with data.

States can be filled with data items that do not yet have data allocated. Fields, FieldBundles, Arrays, and ArrayBundles each have methods that support their creation without actual data allocation - the Grid and Attributes are set up but no Fortran array of data values is allocated. In this approach, when a State is passed into its associated Gridded Component’s initialize method, the incomplete Arrays, Fields, FieldBundles, and ArrayBundles within the State can allocate or reference data inside the initialize method.

States are passed through the interfaces of the Gridded and Coupler Components’ run methods in order to carry data between the components. While we expect a Gridded Component’s import State to be filled with data during initialization, its export State will typically be filled over the course of its run method. At the end of a Gridded Component’s run method, the filled export State is passed out through the argument list into a Coupler Component’s run method. We recommend the convention that it enters the Coupler Component as the Coupler Component’s import State. Here is it transformed into a form that another Gridded Component requires, and passed out of the Coupler Component as its export State. It can then be passed into the run method of a recipient Gridded Component as that component’s import State.

While the above sounds complicated, the rule is simple: a State going into a component is an import State, and a State leaving a component is an export State.

Objects inside States are normally created in unison where each PET executing a component makes the same object create call. If the object contains data, like a Field, each PET may have a different local chunk of the entire dataset but each Field has the same name and is logically one part of a single distributed object. As States are passed between components, if any object in a State was not created in unison on all the current PETs then some PETs have no object to pass into a communication method (e.g. regrid or data redistribution). The ESMF_StateReconcile() method must be called to broadcast information about these objects to all PETs in a component; after which all PETs have a single uniform view of all objects and metadata.

If components are running in sequential mode on all available PETs and States are being passed between them there is no need to call ESMF_StateReconcile since all PETs have a uniform view of the objects. However, if components are running on a subset of the PETs, as is usually the case when running in concurrent mode, then when States
are passed into components which contain a superset of those PETs, for example, a Coupler Component, all PETs
must call `ESMF_StateReconcile` on the States before using them in any ESMF communication methods. The
reconciliation process broadcasts information about objects which exist only on a subset of the PETs. On PETs missing
those objects it creates a proxy object which contains any qualities of the original object plus enough information for
it to be a data source or destination for a regrid or data redistribution operation. There is an option to turn off metadata
reconciliation in the `ESMF_StateReconcile` call.

### 20.3.1 State create and destroy

States can be created and destroyed at any time during application execution. The `ESMF_StateCreate()` routine
can take many different combinations of optional arguments. Refer to the API description for all possible methods of
creating a State. An empty State can be created by providing only a name and type for the intended State:

```python
state = ESMF_StateCreate(name, stateintent=ESMF_STATEINTENT_IMPORT, rc=rc)
```

When finished with an ESMF_State, the `ESMF_StateDestroy` method removes it. However, the objects inside
the ESMF_State created externally should be destroyed separately, since objects can be added to more than one
ESMF_State.

### 20.3.2 Add items to a State

Creation of an empty ESMF_State, and adding an ESMF_FieldBundle to it. Note that the
ESMF_FieldBundle does not get destroyed when the ESMF_State is destroyed; the ESMF_State only con-
tains a reference to the objects it contains. It also does not make a copy; the original objects can be updated and code
accessing them by using the ESMF_State will see the updated version.

```python
statename = "Ocean"
state2 = ESMF_StateCreate(name=statename, &
  stateintent=ESMF_STATEINTENT_EXPORT, rc=rc)
```

```python
bundlename = "Temperature"
bundle1 = ESMF_FieldBundleCreate(name=bundlename, rc=rc)
print *, "FieldBundle Create returned", rc
```

```python
call ESMF_StateAdd(state2, (/bundle1/), rc=rc)
print *, "StateAdd returned", rc
```

```python
call ESMF_StateDestroy(state2, rc=rc)
call ESMF_FieldBundleDestroy(bundle1, rc=rc)
```

### 20.3.3 Add placeholders to a State

If a component could potentially produce a large number of optional items, one strategy is to add the names only of
those objects to the ESMF_State. Other components can call framework routines to set the ESMF_NEEDED flag
to indicate they require that data. The original component can query this flag and then produce only the data that is required by another component.

```plaintext
statename = "Ocean"
state3 = ESMF_StateCreate(name=statename, &
   stateintent=ESMF_STATEINTENT_EXPORT, rc=rc)

dataname = "Downward wind:needed"
call ESMF_AttributeSet (state3, dataname, .false., rc=rc)

dataname = "Humidity:needed"
call ESMF_AttributeSet (state3, dataname, .false., rc=rc)
```

### 20.3.4 Mark an item NEEDED

How to set the NEEDED state of an item.

```plaintext
dataname = "Downward wind:needed"
call ESMF_AttributeSet (state3, name=dataname, value=.true., rc=rc)
```

### 20.3.5 Create a NEEDED item

Query an item for the NEEDED status, and creating an item on demand. Similar flags exist for "Ready", "Valid", and "Required for Restart" to mark each data item as ready, having been validated, or needed if the application is to be checkpointed and restarted. The flags are supported to help coordinate the data exchange between components.

```plaintext
dataname = "Downward wind:needed"
call ESMF_AttributeGet (state3, dataname, valueList=neededFlag, rc=rc)

if (rc == ESMF_SUCCESS .and. neededFlag(1)) then
   bundlename = dataname
   bundle2 = ESMF_FieldBundleCreate(name=bundlename, rc=rc)

   call ESMF_StateAdd(state3, (/bundle2/), rc=rc)
else
   print *, "Data not marked as needed", trim(dataname)
endif
```
20.3.6 ESMF_StateReconcile() usage

The set services routines are used to tell ESMF which routine hold the user code for the initialize, run, and finalize blocks of user level Components. These are the separate subroutines called by the code below.

! Initialize routine which creates "field1" on PETs 0 and 1
subroutine comp1_init(gcomp, istate, ostate, clock, rc)
    type(ESMF_GridComp) :: gcomp
    type(ESMF_State) :: istate, ostate
    type(ESMF_Clock) :: clock
    integer, intent(out) :: rc

    type(ESMF_Field) :: field1
    integer :: localrc

    print *, "i am comp1_init"
    field1 = ESMF_FieldEmptyCreate(name="Comp1 Field", rc=localrc)
    call ESMF_StateAdd(istate, (/field1/), rc=localrc)
    rc = localrc
end subroutine comp1_init

! Initialize routine which creates "field2" on PETs 2 and 3
subroutine comp2_init(gcomp, istate, ostate, clock, rc)
    type(ESMF_GridComp) :: gcomp
    type(ESMF_State) :: istate, ostate
    type(ESMF_Clock) :: clock
    integer, intent(out) :: rc

    type(ESMF_Field) :: field2
    integer :: localrc

    print *, "i am comp2_init"
    field2 = ESMF_FieldEmptyCreate(name="Comp2 Field", rc=localrc)
    call ESMF_StateAdd(istate, (/field2/), rc=localrc)
    rc = localrc
end subroutine comp2_init

subroutine comp_dummy(gcomp, rc)
    type(ESMF_GridComp) :: gcomp
    integer, intent(out) :: rc

    rc = ESMF_SUCCESS
end subroutine comp_dummy

! PROGRAM: ESMF_StateReconcileEx - State reconciliation
!
This program shows examples of using the State Reconcile function.

```fortran
#include "ESMF.h"

! ESMF Framework module
use ESMF
use ESMF_TestMod
use ESMF_StateReconcileEx_Mod
implicit none

! Local variables
integer :: rc, petCount
type(ESMF_State) :: state1
type(ESMF_GridComp) :: comp1, comp2
type(ESMF_VM) :: vm
character(len=ESMF_MAXSTR) :: comp1name, comp2name, statename

A Component can be created which will run only on a subset of the current PET list.

! Get the global VM for this job.
call ESMF_VMGetGlobal(vm=vm, rc=rc)
comp1name = "Atmosphere"
comp1 = ESMF_GridCompCreate(name=comp1name, petList=(/ 0, 1 /), rc=rc)
print *, "GridComp Create returned, name = ", trim(comp1name)

comp2name = "Ocean"
comp2 = ESMF_GridCompCreate(name=comp2name, petList=(/ 2, 3 /), rc=rc)
print *, "GridComp Create returned, name = ", trim(comp2name)

statename = "Ocn2Atm"
state1 = ESMF_StateCreate(name=statename, rc=rc)

Here we register the subroutines which should be called for initialization. Then we call ESMF_GridCompInitialize() on all PETs, but the code runs only on the PETs given in the petList when the Component was created.

Because this example is so short, we call the entry point code directly instead of the normal procedure of nesting it in a separate SetServices() subroutine.

! This is where the VM for each component is initialized.
! Normally you would call SetEntryPoint inside set services,
! but to make this example very short, they are called inline below.
! This is o.k. because the SetServices routine must execute from within
! the parent component VM.
call ESMF_GridCompSetVM(comp1, comp_dummy, rc=rc)
```
call ESMF_GridCompSetVM(comp2, comp_dummy, rc=rc)

call ESMF_GridCompSetServices(comp1, userRoutine=comp_dummy, rc=rc)

call ESMF_GridCompSetServices(comp2, userRoutine=comp_dummy, rc=rc)

print *, "ready to set entry point 1"
call ESMF_GridCompSetEntryPoint(comp1, ESMF_METHODInicialize, &
                          comp1_init, rc=rc)

print *, "ready to set entry point 2"
call ESMF_GridCompSetEntryPoint(comp2, ESMF_METHODInicialize, &
                          comp2_init, rc=rc)

print *, "ready to call init for comp 1"
call ESMF_GridCompInitialize(comp1, exportState=state1, rc=rc)

print *, "ready to call init for comp 2"
call ESMF_GridCompInitialize(comp2, exportState=state1, rc=rc)

Now we have state1 containing field1 on PETs 0 and 1, and state1 containing field2 on PETs 2 and 3. For the code to have a rational view of the data, we call ESMF_StateReconcile which determines which objects are missing from any PET, and communicates information about the object. There is the option of turning metadata reconciliation on or off with the optional parameter shown in the call below. The default behavior is for metadata reconciliation to be off. After the call to reconcile, all ESMF_State objects now have a consistent view of the data.

print *, "State before calling StateReconcile()"
call ESMF_StatePrint(state1, rc=rc)

call ESMF_StateReconcile(state1, vm=vm, &
                          attreconflag=ESMF_ATTRECONCILE_OFF, rc=rc)
print *, "State after calling StateReconcile()"
call ESMF_StatePrint(state1, rc=rc)

end program ESMF_StateReconcileEx

20.3.7 Read Arrays from a netCDF file and add to a State

This program shows an example of reading and writing Arrays from a State from/to a NetCDF file.

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! Local variables
type(ESMF_State) :: state
type(ESMF_Array) :: latArray, lonArray, timeArray, humidArray, &
tempArray, pArray, rhArray
type(ESMF_VM) :: vm
integer :: localPet, rc

The following line of code will read all Array data contained in a NetCDF file, place them in ESMF_Arrays and add them to an ESMF_State. Only PET 0 reads the file; the States in the other PETs remain empty. Currently, the data is not decomposed or distributed; each PET has only 1 DE and only PET 0 contains data after reading the file. Future versions of ESMF will support data decomposition and distribution upon reading a file.

Note that the third party NetCDF library must be installed. For more details, see the "ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, NetCDF" and the website http://www.unidata.ucar.edu/software/netcdf.

! Read the NetCDF data file into Array objects in the State on PET 0
call ESMF_StateRead(state, "io_netcdf_testdata.nc", rc=rc)

! If the NetCDF library is not present (on PET 0), cleanup and exit
if (rc == ESMF_RC_LIB_NOT_PRESENT) then
    call ESMF_StateDestroy(state, rc=rc)
goto 10
endif

Only reading data into ESMF_Arrays is supported at this time; ESMF_ArrayBundles, ESMF_Fields, and ESMF_FieldBundles will be supported in future releases of ESMF.

20.3.8 Print Array data from a State

To see that the State now contains the same data as in the file, the following shows how to print out what Arrays are contained within the State and to print the data contained within each Array. The NetCDF utility "ncdump" can be used to view the contents of the NetCDF file. In this example, only PET 0 will contain data.
if (localPet == 0) then
  ! Print the names and attributes of Array objects contained in the State
  call ESMF_StatePrint(state, rc=rc)

  ! Get each Array by name from the State
  call ESMF_StateGet(state, "lat", latArray, rc=rc)
  call ESMF_StateGet(state, "lon", lonArray, rc=rc)
  call ESMF_StateGet(state, "time", timeArray, rc=rc)
  call ESMF_StateGet(state, "Q", humidArray, rc=rc)
  call ESMF_StateGet(state, "TEMP", tempArray, rc=rc)
  call ESMF_StateGet(state, "p", pArray, rc=rc)
  call ESMF_StateGet(state, "rh", rhArray, rc=rc)

  ! Print out the Array data
  call ESMF_ArrayPrint(latArray, rc=rc)
  call ESMF_ArrayPrint(lonArray, rc=rc)
  call ESMF_ArrayPrint(timeArray, rc=rc)
  call ESMF_ArrayPrint(humidArray, rc=rc)
  call ESMF_ArrayPrint(tempArray, rc=rc)
  call ESMF_ArrayPrint(pArray, rc=rc)
  call ESMF_ArrayPrint(rhArray, rc=rc)
endif

Note that the Arrays "lat", "lon", and "time" hold spatial and temporal coordinate data for the dimensions latitude, longitude and time, respectively. These will be used in future releases of ESMF to create ESMF/Grids.

20.3.9 Write Array data within a State to a netCDF file

All the Array data within the State on PET 0 can be written out to a NetCDF file as follows:

   ! Write Arrays within the State on PET 0 to a NetCDF file
   call ESMF_StateWrite(state, "io_netcdf_testdata_out.nc", rc=rc)

Currently writing is limited to PET 0; future versions of ESMF will allow parallel writing, as well as parallel reading.

20.4 Restrictions and Future Work

1. No synchronization of object ids at object create time. Object IDs are using during the reconcile process to identify objects which are unknown to some subset of the PETs in the currently running VM. Object IDs are assigned in sequential order at object create time.

   One important request by the user community during the ESMF object design was that there be no communication overhead or synchronization when creating distributed ESMF objects. As a consequence it is required to create these objects in unison across all PETs in order to keep the ESMF object identification in sync.

20.5 Design and Implementation Notes

1. States contain the name of the associated Component, a flag for Import or Export, and a list of data objects, which can be a combination of FieldBundles, Fields, and/or Arrays. The objects must be named and have the
proper attributes so they can be identified by the receiver of the data. For example, units and other detailed information may need to be associated with the data as an Attribute.

2. Data contained in States must be created in unison on each PET of the current VM. This allows the creation process to avoid doing communications since each PET can compute any information it needs to know about any remote PET (for example, the grid distribute method can compute the decomposition of the grid on not only the local PET but also the remote PETs since it knows each PET is making the identical call). For all PETs to have a consistent view of the data this means objects must be given unique names when created, or all objects must be created in the same order on all PETs so ESMF can generate consistent default names for the objects.

When running components on subsets of the original VM all the PETs can create consistent objects but then when they are put into a State and passed to a component with a different VM and a different set of PETs, a communication call (reconcile) must be made to communicate the missing information to the PETs which were not involved in the original object creation. The reconcile call broadcasts object lists; those PETs which are missing any objects in the total list can receive enough information to reconstruct a proxy object which contains all necessary information about that object, with no local data, on that PET. These proxy objects can be queried by ESMF routines to determine the amount of data and what PETs contain data which is destined to be moved to the local PET (for receiving data) and conversely, can determine which other PETs are going to receive data and how much (for sending data).

For example, the FieldExcl system test creates 2 Gridded Components on separate subsets of PETs. They use the option of mapping particular, non-monotonic PETs to DEs. The following figures illustrate how the DEs are mapped in each of the Gridded Components in that test:

In the coupler code, all PETs must make the reconcile call before accessing data in the State. On PETs which already contain data, the objects are unchanged. On PETs which were not involved during the creation of the FieldBundles or Fields, the reconcile call adds an object to the State which contains all the same metadata associated with the object, but creates a slightly different Grid object, called a Proxy Grid. These PETs contain no local data, so the Array object is empty, and the DELayout for the Grid is like this:
Figure 8: The mapping of PETs (processors) to DEs (data) in the destination grid created by `user_model2.F90` in the FieldExcl system test.

Figure 9: The mapping of PETs (processors) to DEs (data) in the source grid after the reconcile call in `user_coupler.F90` in the FieldExcl system test.
Figure 10: The mapping of PETs (processors) to DEs (data) in the destination grid after the reconcile call in user_coupler.F90 in the FieldExcl system test.
20.6 Object Model

The following is a simplified UML diagram showing the structure of the State class. States can contain FieldBundles, Fields, Arrays, or nested States. See Appendix A, *A Brief Introduction to UML*, for a translation table that lists the symbols in the diagram and their meaning.

20.7 Class API

20.7.1 ESMF_StateAssignment(=) - State assignment

**INTERFACE:**

```plaintext
interface assignment(=)
state1 = state2
```

**ARGUMENTS:**

```plaintext
type(ESMF_State) :: state1
type(ESMF_State) :: state2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Assign `state1` as an alias to the same ESMF State object in memory as `state2`. If `state2` is invalid, then `state1` will be equally invalid after the assignment.

The arguments are:

- **state1** The `ESMF_State` object on the left hand side of the assignment.
- **state2** The `ESMF_State` object on the right hand side of the assignment.
20.7.2  ESMF_StateOperator(==) - State equality operator

INTERFACE:

    interface operator(==)
    if (state1 == state2) then ... endif
    OR
    result = (state1 == state2)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_State), intent(in) :: state1
    type(ESMF_State), intent(in) :: state2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether state1 and state2 are valid aliases to the same ESMF State object in memory. For a more general comparison of two ESMF States, going beyond the simple alias test, the ESMF_StateMatch() function (not yet implemented) must be used.

The arguments are:

state1 The ESMF_State object on the left hand side of the equality operation.
state2 The ESMF_State object on the right hand side of the equality operation.

20.7.3  ESMF_StateOperator(/=) - State not equal operator

INTERFACE:

    interface operator(/=)
    if (state1 /= state2) then ... endif
    OR
    result = (state1 /= state2)

RETURN VALUE:

    logical :: result
ARGUMENTS:

\[
\begin{align*}
\text{type}(\text{ESMF\_State}), \text{intent}(\text{in}) & : \text{state1} \\
\text{type}(\text{ESMF\_State}), \text{intent}(\text{in}) & : \text{state2}
\end{align*}
\]

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether state1 and state2 are not valid aliases to the same ESMF State object in memory. For a more general comparison of two ESMF States, going beyond the simple alias test, the ESMF\_StateMatch() function (not yet implemented) must be used.

The arguments are:

- \textbf{state1} The \texttt{ESMF\_State} object on the left hand side of the non-equality operation.
- \textbf{state2} The \texttt{ESMF\_State} object on the right hand side of the non-equality operation.

---

20.7.4 ESMF\_StateAdd - Add a list of items to a State

INTERFACE:

\[
\begin{align*}
\text{subroutine ESMF\_StateAdd(state, \text{<itemList>}, \text{relaxedFlag}, \text{rc})}
\end{align*}
\]

ARGUMENTS:

\[
\begin{align*}
\text{type}(\text{ESMF\_State}), \text{intent}(\text{inout}) & : \text{state} \\
\text{<itemList>}, \text{see below for supported values} & \\
\text{-- The following arguments require argument keyword syntax (e.g. rc=rc). --} \\
\text{logical, intent(in), optional : \text{relaxedFlag}} \\
\text{integer, intent(out), optional : \text{rc}}
\end{align*}
\]

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Add a list of items to a \texttt{ESMF\_State}. It is an error if any item in \texttt{<itemlist>} already matches, by name, an item already contained in \texttt{state}.

Supported values for \texttt{<itemList>} are:
The arguments are:

\textbf{state} An \texttt{ESMF\_State} to which the \texttt{<itemList>} will be added.

\texttt{<itemList>} The list of items to be added. This is a reference only; when the \texttt{ESMF\_State} is destroyed the \texttt{<itemList>} items contained within it will not be destroyed. Also, the items in the \texttt{<itemList>} cannot be safely destroyed before the \texttt{ESMF\_State} is destroyed. Since \texttt{<itemList>} items can be added to multiple containers, it remains the responsibility of the user to manage their destruction when they are no longer in use.

\textbf{relaxedflag} A setting of \texttt{.true.} indicates a relaxed definition of "add", where it is not an error if \texttt{<itemList>} contains items with names that are found in \texttt{state}. The \texttt{State} is left unchanged for these items. For \texttt{.false.} this is treated as an error condition. The default setting is \texttt{.false.}.

\textbf{rc} Return code; equals \texttt{ESMF\_SUCCESS} if there are no errors.

\section*{20.7.5 \textit{ESMF\_StateAddReplace} - Add or replace a list of items to a State}

\textbf{INTERFACE:}

\begin{verbatim}
    subroutine ESMF\_StateAddReplace(state, <itemList>, rc)
\end{verbatim}

\textbf{ARGUMENTS:}

\begin{verbatim}
    type(ESMF\_State), intent(inout) :: state
    <itemList>, see below for supported values
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc
\end{verbatim}

\textbf{STATUS:}

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

\textbf{DESCRIPTION:}

Add or replace a list of items to an \texttt{ESMF\_State}. If an item in \texttt{<itemlist>} does not match any items already present in \texttt{state}, it is added. Items with names already present in the \texttt{state} replace the existing item.

Supported values for \texttt{<itemList>} are:
The arguments are:

**state**  An ESMF_State to which the <itemList> will be added or replaced.

**<itemList>**  The list of items to be added or replaced. This is a reference only; when the ESMF_State is destroyed the <itemList> items contained within it will not be destroyed. Also, the items in the <itemList> cannot be safely destroyed before the ESMF_State is destroyed. Since <itemList> items can be added to multiple containers, it remains the responsibility of the user to manage their destruction when they are no longer in use.

**<rc>**  Return code; equals ESMF_SUCCESS if there are no errors.

### 20.7.6 ESMF_StateCreate - Create a new State

**INTERFACE:**

```fortran
function ESMF_StateCreate(stateintent, &
    arrayList, arraybundleList, &
    fieldList, fieldbundleList, &
    nestedStateList, &
    routehandleList, name, rc)
```

**RETURN VALUE:**

```fortran
type(ESMF_State) :: ESMF_StateCreate
```

**ARGUMENTS:**

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

```
type(ESMF_StateIntent_Flag), intent(in), optional :: stateintent
```

```
type(ESMF_Array), intent(in), optional :: arrayList(:)
```

```
type(ESMF_ArrayBundle), intent(in), optional :: arraybundleList(:)
```

```
type(ESMF_Field), intent(in) :: fieldList(:)
```

```
type(ESMF_FieldBundle), intent(in) :: fieldbundleList(:)
```

```
type(ESMF_RouteHandle), intent(in) :: routehandleList(:)
```

```
type(ESMF_State), intent(in) :: nestedStateList(:)
```

```
character(len= *), intent(in), optional :: name
```

**STATUS:**

184
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create a new ESMF_State, set default characteristics for objects added to it, and optionally add initial objects to it. The arguments are:

[stateintent] Import or Export ESMF_State. Valid values are ESMF_STATEINTENT_IMPORT, ESMF_STATEINTENT_EXPORT, or ESMF_STATEINTENT_UNSPECIFIED The default is ESMF_STATEINTENT_UNSPECIFIED.
[arrayList] A list (Fortran array) of ESMF_Arrays.
[arraybundleList] A list (Fortran array) of ESMF_ArrayBundles.
[fieldList] A list (Fortran array) of ESMF_FieldBundles.
[fieldbundleList] A list (Fortran array) of ESMF_FieldBundles.
[nestedStateList] A list (Fortran array) of ESMF_States to be nested inside the outer ESMF_State.
[routehandleList] A list (Fortran array) of ESMF_RouteHandles.
[name] Name of this ESMF_State object. A default name will be generated if none is specified.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

20.7.7 ESMF_StateDestroy - Release resources for a State

INTERFACE:

recursive subroutine ESMF_StateDestroy(state, rc)

ARGUMENTS:

type(ESMF_State), intent(inout) :: state
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Releases resources associated with this ESMF_State. Actual objects added to ESMF_States will not be destroyed, it remains the responsibility of the user to destroy these objects in the correct context.

The arguments are:
state  Destroy contents of this ESMF_State.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

20.7.8   ESMF_StateGet - Get object-wide information from a State

INTERFACE:

    ! Private name; call using ESMF_StateGet()
    subroutine ESMF_StateGetInfo(state, &
        itemSearch, itemorderflag, nestedFlag, &
        stateintent, itemCount, itemNameList, itemTypeList, name, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
        -- The following arguments require argument keyword syntax (e.g. rc=rc). --
        character (len=*), intent(in), optional :: itemSearch
        type(ESMF_ItemOrder_Flag), intent(in), optional :: itemorderflag
        logical, intent(in), optional :: nestedFlag
        type(ESMF_StateIntent_Flag), intent(out), optional :: stateintent
        integer, intent(out), optional :: itemCount
        character (len=*), intent(out), optional :: itemNameList(:)
        type(ESMF_StateItem_Flag), intent(out), optional :: itemTypeList(:)
        character (len=*), intent(out), optional :: name
        integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.
Changes made after the 5.2.0r release:

6.1.0  Added argument itemorderflag. The new argument gives the user control over the order in which the items are returned.

DESCRIPTION:

Returns the requested information about this ESMF_State. The optional itemSearch argument may specify the name of an individual item to search for. When used in conjunction with the nestedFlag, nested States will also be searched.

Typically, an ESMF_StateGet() information request will be performed twice. The first time, the itemCount argument will be used to query the size of arrays that are needed. Arrays can then be allocated to the correct size for itemNameList and itemTypeList as needed. A second call to ESMF_StateGet() will then fill in the values.

The arguments are:
state  An ESMF_State object to be queried.

[itemSearch] Query objects by name in the State. When the nestedFlag option is set to .true., all nested States will also be searched for the specified name.

[nestedFlag] When set to .false., returns information at the current State level only (default). When set to .true., additionally returns information from nested States.

[stateintent] Returns the type, e.g., Import or Export, of this ESMF_State. Possible values are listed in Section 20.2.1.

[itemCount] Count of items in this ESMF_State. When the nestedFlag option is set to .true., the count will include items present in nested States. When using itemSearch, it will count the number of items matching the specified name.

[itemNameList] Array of item names in this ESMF_State. When the nestedFlag option is set to .true., the list will include items present in nested States. When using itemSearch, it will return the names of items matching the specified name. itemNameList must be at least itemCount long.

[itemTypeList] Array of possible item object types in this ESMF_State. When the nestedFlag option is set to .true., the list will include items present in nested States. When using itemSearch, it will return the types of items matching the specified name. Must be at least itemCount long. Return values are listed in Section 20.2.2.

[name] Returns the name of this ESMF_State.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

20.7.9  ESMF_StateGet - Get information about an item in a State by item name

INTERFACE:

    ! Private name; call using ESMF_StateGet()
    subroutine ESMF_StateGetItemInfo(state, itemName, itemType, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
    character (len=*), intent(in) :: itemName
    type(ESMF_StateItem_Flag), intent(out) :: itemType
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Returns the type for the item named name in this ESMF_State. If no item with this name exists, the value ESMF_STATEITEM_NOTFOUND will be returned and the error code will not be set to an error. Thus this routine can be used to safely query for the existence of items by name whether or not they are expected to be there. The error code will be set in case of other errors, for example if the ESMF_State itself is invalid.

The arguments are:

state  ESMF_State to be queried.

itemName  Name of the item to return information about.

itemType  Returned item types for the item with the given name, including placeholder names. Options are listed in Section 20.2.2. If no item with the given name is found, ESMF_STATEITEM_NOTFOUND will be returned and rc will not be set to an error.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

20.7.10  ESMF_StateGet - Get an item from a State by item name

INTERFACE:

subroutine ESMF_StateGet(state, itemName, <item>, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
    character (len=*), intent(in) :: itemName
    <item>, see below for supported values
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns an <item> from an ESMF_State by item name. If the ESMF_State contains the <item> directly, only itemName is required.

If the state contains nested ESMF_States, the itemName argument may specify a fully qualified name to access the desired item with a single call. This is performed using the “/” character to separate the names of the intermediate State names leading to the desired item. (E.g., itemName=”state1/state12/item”).

Supported values for <item> are:

    type(ESMF_Array), intent(out) :: array
The arguments are:

state  State to query for an <item> named itemName.

itemName  Name of <item> to be returned. This name may be fully qualified in order to access nested State items.

<item>  Returned reference to the <item>.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

---

20.7.11  ESMF_StatePrint - Print State information

INTERFACE:

    subroutine ESMF_StatePrint(state, options, nestedFlag, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
    character(len=*), intent(in), optional :: options
    logical, intent(in), optional :: nestedFlag
    integer, intent(out), optional :: rc

DESCRIPTION:

Prints information about the state to stdout.

The arguments are:

state  The ESMF_State to print.

[options]  Print options: " ", or "brief" - print names and types of the objects within the state (default), "long" - print additional information, such as proxy flags

[nestedFlag]  When set to .false., prints information about the current State level only (default), When set to .true., additionally prints information from nested States

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
20.7.12 ESMF_StateRead – Read data items from a file into a State

INTERFACE:

    subroutine ESMF_StateRead(state, fileName, rc)

ARGUMENTS:

    type(ESMF_State), intent(inout) :: state
    character (len=*), intent(in) :: fileName
    integer, intent(out), optional :: rc

DESCRIPTION:

Currently limited to read in all Arrays from a netCDF file and add them to a State object. Future releases will enable more items of a State to be read from a file of various formats.

Only PET 0 reads the file; the States in other PETs remain empty. Currently, the data is not decomposed or distributed; each PET has only 1 DE and only PET 0 contains data after reading the file. Future versions of ESMF will support data decomposition and distribution upon reading a file. See Section 20.3.7 for an example.

Note that the third party NetCDF library must be installed. For more details, see the "ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, NetCDF" and the website http:

The arguments are:

    state  The ESMF_State to add items read from file. Currently only Arrays are supported.
    fileName  File to be read.
    [rc]  Return code; equals ESMF_SUCCESS if there are no errors. Equals ESMF_RC_LIB_NOT_PRESENT if the NetCDF library is not present.

20.7.13 ESMF_StateReconcile – Reconcile State data across all PETs in a VM

INTERFACE:

    subroutine ESMF_StateReconcile(state, vm, attreconflag, rc)

ARGUMENTS:

    type(ESMF_State), intent(inout) :: state
    type(ESMF_VM), intent(in), optional :: vm
    type(ESMF_AttReconcileFlag), intent(in), optional :: attreconflag
    integer, intent(out), optional :: rc

DESCRIPTION:

Must be called for any ESMF_State which contains ESMF objects that have not been created on all the PETs of the currently running ESMF_Component. For example, if a coupler is operating on data which was created by another
component that ran on only a subset of the coupler’s PETs, the coupler must make this call first before operating on any data inside that ESMF_State. After calling ESMF_StateReconcile all PETs will have a common view of all objects contained in this ESMF_State. The option to reconcile the metadata associated with the objects contained in this ESMF_State also exists. The default behavior for this capability is to not reconcile metadata unless told otherwise.

The arguments are:

- **state** ESMF_State to reconcile.
- **[vm]** ESMF_VM for this ESMF_Component. By default, it set to the current vm.
- **[attreconflag]** Flag to tell if Attribute reconciliation is to be done as well as data reconciliation. This flag is documented in section 50.4.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

### 20.7.14 ESMF_StateRemove - Remove an item from a State - (DEPRECATED METHOD)

**INTERFACE:**

```fortran
! Private name; call using ESMF_StateRemove ()
subroutine ESMF_StateRemoveOneItem (state, itemName, &
   relaxedFlag, rc)
```

**ARGUMENTS:**

- `type(ESMF_State), intent(inout) :: state`
- `character(*), intent(in) :: itemName`
- `logical, intent(in), optional :: relaxedFlag`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- **DEPRECATED METHOD** as of ESMF 5.3.1. Please use ESMF_StateRemove instead. Rationale: The list version is consistent with other ESMF container operations which use lists.

**DESCRIPTION:**

Remove an existing reference to an item from a State.

The arguments are:

- **state** The ESMF_State within which itemName will be removed.
- **itemName** The name of the item to be removed. This is a reference only. The item itself is unchanged.

If the state contains nested ESMF_States, the itemName argument may specify a fully qualified name to remove the desired item with a single call. This is performed using the "/" character to separate the names of the intermediate State names leading to the desired item. (E.g., itemName="statel/state12/item".
Since an item could potentially be referenced by multiple containers, it remains the responsibility of the user to manage its destruction when it is no longer in use.

**relaxedflag**  A setting of .true. indicates a relaxed definition of "remove", where it is not an error if itemName is not present in the state. For .false. this is treated as an error condition. The default setting is .false..

**rc**  Return code; equals ESMF_SUCCESS if there are no errors.

### 20.7.15 ESMF_StateRemove - Remove a list of items from a State

**INTERFACE:**

```plaintext
! Private name; call using ESMF_StateRemove ()
subroutine ESMF_StateRemoveList (state, itemNameList, relaxedFlag, rc)
```

**ARGUMENTS:**

- `type(ESMF_State), intent(inout) :: state`
- `character(*), intent(in) :: itemNameList(:)`
- `logical, intent(in), optional :: relaxedFlag`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.3.1. If code using this interface compiles with any version of ESMF starting with 5.3.1, then it will compile with the current version.

**DESCRIPTION:**

Remove existing references to items from a State.

The arguments are:

- `state`  The ESMF_State within which itemName will be removed.
- `itemNameList`  The name of the items to be removed. This is a reference only. The items themselves are unchanged.

If the state contains nested ESMF_States, the itemName arguments may specify fully qualified names to remove the desired items with a single call. This is performed using the "/" character to separate the names of the intermediate State names leading to the desired items. (E.g., itemName="state1/state12/item".

Since items could potentially be referenced by multiple containers, it remains the responsibility of the user to manage their destruction when they are no longer in use.

**relaxedflag**  A setting of .true. indicates a relaxed definition of "remove", where it is not an error if an item in the itemNameList is not present in the state. For .false. this is treated as an error condition. The default setting is .false..

**rc**  Return code; equals ESMF_SUCCESS if there are no errors.
20.7.16  ESMF_StateReplace - Replace a list of items within a State

INTERFACE:

    subroutine ESMF_StateReplace(state, <itemList>, relaxedflag, rc)

ARGUMENTS:

    type(ESMF_State), intent(inout) :: state
    <itemList>, see below for supported values
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: relaxedflag
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Replace a list of items with an ESMF_State. If an item in <itemList> does not match any items already present in state, an error is returned.

Supported values for <itemList> are:

    type(ESMF_Array), intent(in) :: arrayList(:)
    type(ESMF_ArrayBundle), intent(in) :: arraybundleList(:)
    type(ESMF_Field), intent(in) :: fieldList(:)
    type(ESMF_FieldBundle), intent(in) :: fieldbundleList(:)
    type(ESMF_RouteHandle), intent(in) :: routehandleList(:)
    type(ESMF_State), intent(in) :: nestedStateList(:)

The arguments are:

state  An ESMF_State within which the <itemList> items will be replaced.

<itemList>  The list of items to be replaced. This is a reference only; when the ESMF_State is destroyed the <itemList> contained in it will not be destroyed. Also, the items in the <itemList> cannot be safely destroyed before the ESMF_State is destroyed. Since <itemList> items can be added to multiple containers, it remains the responsibility of the user to manage their destruction when they are no longer in use.

[relaxedflag]  A setting of .true. indicates a relaxed definition of "replace", where it is not an error if <itemList> contains items with names that are not found in state. The State is left unchanged for these items. For .false. this is treated as an error condition. The default setting is .false..

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
20.7.17 ESMF_StateValidate - Check validity of a State

INTERFACE:

    subroutine ESMF_StateValidate(state, nestedFlag, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: nestedFlag
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Validates that the state is internally consistent. Currently this method determines if the State is uninitialized or already destroyed. The method returns an error code if problems are found.

The arguments are:

state The ESMF_State to validate.
[nestedFlag] .false. - validates at the current State level only (default) .true. - recursively validates any nested States
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

20.7.18 ESMF_StateWrite – Write items from a State to file

INTERFACE:

    subroutine ESMF_StateWrite(state, fileName, rc)

ARGUMENTS:

    type(ESMF_State), intent(in) :: state
    character (len=*), intent(in) :: fileName
    integer, intent(out), optional :: rc

DESCRIPTION:

Currently limited to write out all Arrays of a State object to a netCDF file. Future releases will enable more item types of a State to be written to files of various formats.
Writing is currently limited to PET 0; future versions of ESMF will allow parallel writing, as well as parallel reading. See Section 20.3.7 for an example.

Note that the third party NetCDF library must be installed. For more details, see the "ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, NetCDF" and the website http://www.unidata.ucar.edu/software/netcdf.

The arguments are:

- **state** The ESMF_State from which to write items. Currently limited to Arrays.
- **fileName** File to be written.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors. Equals ESMF_RC_LIB_NOT_PRESENT if the NetCDF library is not present.

## 21 Attachable Methods

### 21.1 Description

ESMF allows user methods to be attached to Components and States. Providing this capability supports a more object oriented way of model design.

Attachable methods on Components can be used to implement the concept of generic Components where the specialization requires attaching methods with well defined names. This methods are then called by the generic Component code.

Attaching methods to States can be used to supply data operations along with the data objects inside of a State object. This can be useful where a producer Component not only supplies a data set, but also the associated processing functionality. This can be more efficient than providing all of the possible sets of derived data.

### 21.2 Use and Examples

The following examples demonstrate how a producer Component attaches a user defined method to a State, and how it implements the method. The attached method is then executed by the consumer Component.

#### 21.2.1 Producer Component attaches user defined method

The producer Component attaches a user defined method to `exportState` during the Component’s initialize method. The user defined method is attached with label `finalCalculation` by which it will become accessible to the consumer Component.

```fortran
subroutine init(gcomp, importState, exportState, clock, rc)
  ! arguments
  type(ESMF_GridComp):: gcomp
  type(ESMF_State):: importState, exportState
  type(ESMF_Clock):: clock
  integer, intent(out):: rc

  call ESMF_MethodAdd(exportState, label="finalCalculation", &
```
userRoutine=finalCalc, rc=rc)

rc = 0
end subroutine !----------------------------------------------------------

21.2.2 Producer Component implements user defined method

The producer Component implements the attached, user defined method finalCalc. Strict interface rules apply for the user defined method.

subroutine finalCalc(state, rc)
  ! arguments
  type(ESMF_State):: state
  integer, intent(out):: rc

  ! access data objects in state and perform calculation
  print *, "dummy output from attached method "
  rc = 0
end subroutine !----------------------------------------------------------

21.2.3 Consumer Component executes user defined method

The consumer Component executes the user defined method on the importState.

subroutine init(gcomp, importState, exportState, clock, rc)
  ! arguments
  type(ESMF_GridComp):: gcomp
  type(ESMF_State):: importState, exportState
  type(ESMF_Clock):: clock
  integer, intent(out):: rc

  integer:: userRc

  call ESMF_MethodExecute(importState, label="finalCalculation", &
                          userRc=userRc, rc=rc)
  rc = 0
end subroutine !----------------------------------------------------------

21.3 Restrictions and Future Work

1. Not reconciled. Attachable Methods are PET-local settings on an object. Currently Attachable Methods cannot be reconciled (i.e. ignored during ESMF_StateReconcile()).

2. No copy nor move. Currently Attachable Methods cannot be copied or moved between objects.
21.4 Class API

21.4.1 ESMF_MethodAdd - Attach user method to State

INTERFACE:

! Private name; call using ESMF_MethodAdd()
subroutine ESMF_MethodStateAdd(state, label, index, userRoutine, rc)

ARGUMENTS:

  type(ESMF_State) :: state
  character(len=*), intent(in) :: label
  integer, intent(in), optional :: index
  interface
    subroutine userRoutine(state, rc)
      use ESMF_StateMod
      implicit none
      type(ESMF_State) :: state ! must not be optional
      integer, intent(out) :: rc ! must not be optional
    end subroutine
  end interface
  integer, intent(out), optional :: rc

DESCRIPTION:

Attach userRoutine.
The arguments are:

state  The ESMF_State to attach to.
label  Label of method.
[index] Integer modifier to distinguish multiple entries with the same label.
userRoutine  The user-supplied subroutine to be associated with the label.

  The subroutine must have the exact interface shown above for the userRoutine argument. Arguments in
  userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine
  must be either a module scope procedure, or an external procedure that has a matching interface block specified
  for it. It must not be an internal procedure which is contained within another procedure.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

21.4.2 ESMF_MethodAdd - Attach user method, located in shared object, to State

INTERFACE:
subroutine ESMF_MethodStateAddShObj(state, label, index, userRoutine, &
sharedObj, rc)

ARGUMENTS:

type(ESMF_State) :: state
character(len=*) intent(in) :: label
integer, intent(in), optional :: index
character(len=*) intent(in) :: userRoutine
character(len=*) intent(in), optional :: sharedObj
integer, intent(out), optional :: rc

DESCRIPTION:

Attach userRoutine.
The arguments are:

state  The ESMF_State to attach to.
label  Label of method.
[index] Integer modifier to distinguish multiple entries with the same label.
userRoutine  Name of user-supplied subroutine to be associated with the label, specified as a character string.

The subroutine must have the exact interface shown in ESMF_MethodStateAdd for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

sharedObj  Name of shared object that contains userRoutine. If the sharedObj argument is not provided the executable itself will be searched for userRoutine.

rc  Return code; equals ESMF_SUCCESS if there are no errors.

21.4.3 ESMF_MethodExecute - Execute user method attached to State

INTERFACE:

subroutine ESMF_MethodStateExecute(state, label, index, existflag, &
userRc, rc)

ARGUMENTS:

type(ESMF_State) :: state
character(len=*) intent(in) :: label
integer, intent(in), optional :: index
logical intent(out), optional :: existflag
integer, intent(out), optional :: userRc
integer, intent(out), optional :: rc
DESCRIPTION:

Execute attached method.

The arguments are:

state  The ESMF_State to attach to.

label  Label of method.

[index]  Integer modifier to distinguish multiple entries with the same label.

[existflag]  Returned .true. indicates that the method specified by label exists and was executed. A return value of .false. indicates that the method does not exist and consequently was not executed. By default, i.e. if existflag was not specified, the latter condition will lead to rc not equal ESMF_SUCCESS being returned. However, if existflag was specified, a method not existing is not an error condition.

[userRc]  Return code set by attached method before returning.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

21.4.4  ESMF_MethodRemove - Remove user method attached to State

INTERFACE:

! Private name; call using ESMF_MethodRemove()
subroutine ESMF_MethodStateRemove(state, label, index, rc)

ARGUMENTS:

  type(ESMF_State) :: state
  character(len=*), intent(in) :: label
  integer, intent(in), optional :: index
  integer, intent(out), optional :: rc

DESCRIPTION:

Remove attached method.

The arguments are:

state  The ESMF_State to attach to.

label  Label of method.

[index]  Integer modifier to distinguish multiple entries with the same label.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
21.4.5 ESMF_MethodAdd - Attach user method to GridComp

INTERFACE:

! Private name; call using ESMF_MethodAdd()
subroutine ESMF_MethodGridCompAdd(gcomp, label, index, userRoutine, rc)

ARGUMENTS:

  type(ESMF_GridComp) :: gcomp
  character(len=*) , intent(in) :: label
  integer, intent(in), optional :: index
  interface
    subroutine userRoutine(gcomp, rc)
        use ESMF_CompMod
        implicit none
        type(ESMF_GridComp) :: gcomp ! must not be optional
        integer, intent(out) :: rc ! must not be optional
    end subroutine
  end interface
  integer, intent(out), optional :: rc

DESCRIPTION:

Attach userRoutine.

The arguments are:

gcomp The ESMF_GridComp to attach to.
label Label of method.

[index] Integer modifier to distinguish multiple entries with the same label.

userRoutine The user-supplied subroutine to be associated with the label.

  The subroutine must have the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

21.4.6 ESMF_MethodAdd - Attach user method, located in shared object, to GridComp

INTERFACE:

! Private name; call using ESMF_MethodAdd()
subroutine ESMF_MethodGridCompAddShObj(gcomp, label, index, userRoutine, &
  sharedObj, rc)
**ARGUMENTS:**

- `type(ESMF_GridComp) :: gcomp`  
  The ESMF_GridComp to attach to.
- `character(len=*)`, intent(in) :: `label`  
  Label of method.
- `integer, intent(in), optional :: index`  
  Integer modifier to distinguish multiple entries with the same `label`.
- `character(len=*)`, intent(in), optional :: `userRoutine`  
  Name of user-supplied subroutine to be associated with the `label`, specified as a character string. The subroutine must have the exact interface shown in `ESMF_MethodGridCompAdd` for the `userRoutine` argument. Arguments in `userRoutine` must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.
- `character(len=*)`, intent(in), optional :: `sharedObj`  
  Name of shared object that contains `userRoutine`. If the `sharedObj` argument is not provided the executable itself will be searched for `userRoutine`.
- `integer, intent(out), optional :: rc`  
  Return code; equals `ESMF_SUCCESS` if there are no errors.

**DESCRIPTION:**

Attach `userRoutine`.

The arguments are:

- **gcomp** The ESMF_GridComp to attach to.
- **label** Label of method.
- **[index]** Integer modifier to distinguish multiple entries with the same `label`.
- **[userRoutine]** Name of user-supplied subroutine to be associated with the `label`, specified as a character string.
- **[sharedObj]** Name of shared object that contains `userRoutine`. If the `sharedObj` argument is not provided the executable itself will be searched for `userRoutine`.
- **[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

---

**21.4.7 ESMF_MethodAdd - Attach user method to CplComp**

**INTERFACE:**

```
! Private name; call using ESMF_MethodAdd()
subroutine ESMF_MethodCplCompAdd(cplcomp, label, index, userRoutine, rc)
```

**ARGUMENTS:**

- `type(ESMF_CplComp) :: cplcomp`  
  ! must not be optional
- `character(len=*)`, intent(in) :: `label`  
  ! must not be optional
- `integer, intent(in), optional :: index`  
- `interface`  
  - `subroutine userRoutine(cplcomp, rc)`  
  - `use ESMF_CompMod`  
  - `implicit none`  
  - `type(ESMF_CplComp) :: cplcomp`  
  - `integer, intent(out) :: rc`  
- `end subroutine`  
- `end interface`  
- `integer, intent(out), optional :: rc`
DESCRIPTION:

Attach userRoutine.

The arguments are:

**cplcomp**  The ESMF_CplComp to attach to.

**label**  Label of method.

[index]  Integer modifier to distinguish multiple entries with the same label.

**userRoutine**  The user-supplied subroutine to be associated with the label.

The subroutine must have the exact interface shown above for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

---

21.4.8  ESMF_MethodAdd - Attach user method, located in shared object, to CplComp

INTERFACE:

```fortran
! Private name; call using ESMF_MethodAdd()
subroutine ESMF_MethodCplCompAddShObj(cplcomp, label, index, userRoutine, &
sharedObj, rc)
```

**ARGUMENTS:**

\[\begin{align*}
\text{type(ESMF_CplComp)} & \quad :: \text{cplcomp} \\
\text{character(len=*), intent(in)} & \quad :: \text{label} \\
\text{integer, intent(in), optional} & \quad :: \text{index} \\
\text{character(len=*), intent(in)} & \quad :: \text{userRoutine} \\
\text{character(len=*), intent(in), optional} & \quad :: \text{sharedObj} \\
\text{integer, intent(out), optional} & \quad :: \text{rc}
\end{align*}\]

DESCRIPTION:

Attach userRoutine.

The arguments are:

**cplcomp**  The ESMF_CplComp to attach to.

**label**  Label of method.

[index]  Integer modifier to distinguish multiple entries with the same label.
userRoutine  Name of user-supplied subroutine to be associated with the label, specified as a character string.

The subroutine must have the exact interface shown in ESMF_MethodCplCompAdd for the userRoutine argument. Arguments in userRoutine must not be declared as optional, and the types, intent and order must match. The subroutine must be either a module scope procedure, or an external procedure that has a matching interface block specified for it. It must not be an internal procedure which is contained within another procedure.

[sharedObj] Name of shared object that contains userRoutine. If the sharedObj argument is not provided the executable itself will be searched for userRoutine.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

21.4.9 ESMF_MethodExecute - Execute user method attached to GridComp

INTERFACE:

! Private name; call using ESMF_MethodExecute()
subroutine ESMF_MethodGridCompExecute(gcomp, label, index, existflag, &
    userRc, rc)

ARGUMENTS:

    type(ESMF_GridComp) :: gcomp
    character(len=*) , intent(in) :: label
    integer, intent(in), optional :: index
    logical, intent(out), optional :: existflag
    integer, intent(out), optional :: userRc
    integer, intent(out), optional :: rc

DESCRIPTION:

Execute attached method.

The arguments are:

gcomp  The ESMF_GridComp to attach to.

label  Label of method.

[index] Integer modifier to distinguish multiple entries with the same label.

[existflag] Returned .true. indicates that the method specified by label exists and was executed. A return value of .false. indicates that the method does not exist and consequently was not executed. By default, i.e. if existflag was not specified, the latter condition will lead to rc not equal ESMF_SUCCESS being returned. However, if existflag was specified, a method not existing is not an error condition.

[userRc] Return code set by attached method before returning.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
### 21.4.10 ESMF_MethodExecute - Execute user method attached to CplComp

**INTERFACE:**

```fortran
! Private name; call using ESMF_MethodExecute()
subroutine ESMF_MethodCplCompExecute(cplcomp, label, index, existflag, &
         userRc, rc)
```

**ARGUMENTS:**

- `type(ESMF_CplComp) :: cplcomp`
- `character(len=*), intent(in) :: label`
- `integer, intent(in), optional :: index`
- `logical, intent(out), optional :: existflag`
- `integer, intent(out), optional :: userRc`
- `integer, intent(out), optional :: rc`

**DESCRIPTION:**

Execute attached method.

The arguments are:

- **cplcomp** The `ESMF_CplComp` to attach to.
- **label** Label of method.
- **[index]** Integer modifier to distinguish multiple entries with the same `label`.
- **[existflag]** Returned `.true.` indicates that the method specified by `label` exists and was executed. A return value of `.false.` indicates that the method does not exist and consequently was not executed. By default, i.e. if `existflag` was not specified, the latter condition will lead to `rc` not equal `ESMF_SUCCESS` being returned. However, if `existflag` was specified, a method not existing is not an error condition.
- **[userRc]** Return code set by attached method before returning.
- **[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

### 21.4.11 ESMF_MethodRemove - Remove user method attached to GridComp

**INTERFACE:**

```fortran
! Private name; call using ESMF_MethodRemove()
subroutine ESMF_MethodGridCompRemove(gcomp, label, index, rc)
```

**ARGUMENTS:**

- `type(ESMF_GridComp) :: gcomp`
- `character(len=*), intent(in) :: label`
- `integer, intent(in), optional :: index`
- `integer, intent(out), optional :: rc`
DESCRIPTION:

Remove attached method.
The arguments are:

- **gcomp** The ESMF_GridComp to attach to.
- **label** Label of method.
- **[index]** Integer modifier to distinguish multiple entries with the same **label**.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

21.4.12 ESMF_MethodRemove - Remove user method attached to CplComp

INTERFACE:

```fortran
! Private name; call using ESMF_MethodRemove()
subroutine ESMF_MethodCplCompRemove(cplcomp, label, index, rc)
ARGUMENTS:

type(ESMF_CplComp) :: cplcomp
character(len=*), intent(in) :: label
integer, intent(in), optional :: index
integer, intent(out), optional :: rc
```

DESCRIPTION:

Remove attached method.
The arguments are:

- **cplcomp** The ESMF_CplComp to attach to.
- **label** Label of method.
- **[index]** Integer modifier to distinguish multiple entries with the same **label**.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

22 Web Services

22.1 Description

The goal of the ESMF Web Services is to provide the tools to allow ESMF Users to make their Components available via a web service. The first step is to make the Component a service, and then make it accessible via the Web.
Figure 11: The diagram describes the ESMF Web Services software architecture. The architecture defines a multi-tiered set of applications that provide a flexible approach for accessing model components.
At the heart of this architecture is the Component Service; this is the application that does the model work. The ESMF Web Services part provides a way to make the model accessible via a network API (Application Programming Interface). ESMF provides the tools to turn a model component into a service as well as the tools to access the service from the network.

The Process Controller is a stand-alone application that provides a control mechanism between the end user and the Component Service. The Process Controller is responsible for managing client information as well as restricting client access to a Component Service. (The role of the Process Controller is expected to expand in the future.)

The tomcat/axis2 application provides the access via the Web using standard SOAP protocols. Part of this application includes the SOAP interface definition (using a WSDL file) as well as some java code that provides the access to the Process Controller application.

Finally, the Registrar maintains a list of Component Services that are currently available; Component Services register themselves with the Registrar when they startup, and unregister themselves when they shutdown. The list of available services is maintained in an XML file and is accessible from the Registrar using its network API.

22.1.1 Creating a Service around a Component

22.1.2 Code Modifications

One of the goals in providing the tools to make Components into services was to make the process as simple and easy as possible. Any model component that has been implemented using the ESMF Component Framework can easily be turned into a Component Services with just a minor change to the Application driver code. (For details on the ESMF Framework, see the ESMF Developers Documentation.)

The primary function in ESMF Web Services is the ESMF_WebServicesLoop routine. This function registers the Component Service with the Registrar and then sets up a network socket service that listens for requests from a client. It starts a loop that waits for incoming requests and manages the routing of these requests to all PETs. It is also responsible for making sure the appropriate ESMF routine (ESMF_Initialize, ESMF_Run or ESMF_Finalize) is called based on the incoming request. When the client has completed its interaction with the Component Service, the loop will be terminated and it will unregister the Component Service from the Registrar.

To make all of this happen, the Application Driver just needs to replace its calls to ESMF_Initialize, ESMF_Run, and ESMF_Finalize with a single call to ESMF_WebServicesLoop.

```latex
use ESMF_WebServMod
....

call ESMF_WebServicesLoop(gridComponent, portNumber, returnCode)
```

That’s all there is to turning an ESMF Component into a network-accessible ESMF Component Service. For a detailed example of an ESMF Component turned into an ESMF Component Service, see the Examples in the Web Services section of the Developer’ Guide.
22.1.3 Accessing the Service

Now that the Component is available as a service, it can be accessed remotely by any client that can communicate via TCP sockets. The ESMF library, in addition to providing the service tools, also provides the classes to create C++ clients to access the Component Service via the socket interface.

However, the goal of ESMF Web Services is to make an ESMF Component accessible through a standard web service, which is accomplished through the Process Controller and the Tomcat/Axis2 applications.

22.1.4 Client Application via C++ API

Interfacing to a Component service is fairly simple using the ESMF library. The following code is a simple example of how to interface to a Component Service in C++ and request the initialize operation (the entire sample client can be found in the Web Services examples section of the ESMF Distribution):

```c
#include "ESMCI_WebServCompSvrClient.h"

int main(int argc, char* argv[])
{
    int portNum = 27060;
    int clientId = 101;
    int rc = ESMF_SUCCESS;

    ESMCI::ESMCI_WebServCompSvrClient
        client("localhost", portNum, clientId);

    rc = client.init();
    printf("Initialize return code: %d\n", rc);
}
```

To see a complete description of the NetEsmfClient class, refer to the netesmf library section of the Web Services Reference Manual.

22.1.5 Process Controller

The Process Controller is basically just a instance of a C++ client application. It manages client access to the Component Service (only 1 client can access the service at a time), and will eventually be responsible for starting up and shutting down instances of Component Services (planned for a future release). The Process Controller application is built with the ESMF library and is included in the apps section of the distribution.

22.1.6 Tomcat/Axis2

The Tomcat/Axis2 "application" is essentially the Apache Tomcat server using the Apache Axis2 servlet to implement web services using SOAP protocols. The web interface is defined by a WSDL file, and its implementation is handled by the Component Connector java code. Tomcat and Axis2 are both open source projects that should be downloaded from the Apache web site, but the WSDL file, the Component Connector java code, and all required software for
supporting the interface can be found next to the ESMF distribution in the web_services_server directory. This code is not included with the ESMF distribution because they can be distributed and installed independent of each other.

22.2 Use and Examples

The following examples demonstrate how to use WebServices. ....

22.2.1 Making a Component available through WebServices

In this example a standard ESMF Component is made available through the WebServices interface.

The first step is to make sure your callback routines for initialize, run and finalize are setup. This is done by creating a register routine that sets the entry points for each of these callbacks. In this example, we’ve packaged it all up into a separate module.

```fortran
module ESMF_WebServUserModel
  ! ESMF Framework module
  use ESMF
  implicit none
  public ESMF_WebServUserModelRegister
  contains
    !-------------------------------------------------- -----------------------
    ! The Registration routine
    !
    subroutine ESMF_WebServUserModelRegister(comp, rc)
      type(ESMF_GridComp) :: comp
      integer, intent(out) :: rc
      
      ! Initialize return code
      rc = ESMF_SUCCESS
      print *, "User Comp1 Register starting"
      ! Register the callback routines.
      call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_INITIALIZE, &
          userRoutine=user_init, rc=rc)
      if (rc/=ESMF_SUCCESS) return ! bail out
      call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_RUN, &
          userRoutine=user_run, rc=rc)
      if (rc/=ESMF_SUCCESS) return ! bail out
      call ESMF_GridCompSetEntryPoint(comp, ESMF_METHOD_FINALIZE, &
          userRoutine=user_final, rc=rc)
      if (rc/=ESMF_SUCCESS) return ! bail out
      print *, "Registered Initialize, Run, and Finalize routines"

end subroutine ESMF_WebServUserModelRegister

end module ESMF_WebServUserModel
```

209
print *, "User Comp1 Register returning"
end subroutine

!-------------------------------------------------- -----------------------
! The Initialization routine
!
subroutine user_init(comp, importState, exportState, clock, rc)
type(ESMF_GridComp) :: comp
type(ESMF_State) :: importState, exportState
type(ESMF_Clock) :: clock
integer, intent(out) :: rc

! Initialize return code
rc = ESMF_SUCCESS

print *, "User Comp1 Init"
end subroutine user_init

!-------------------------------------------------- -----------------------
! The Run routine
!
subroutine user_run(comp, importState, exportState, clock, rc)
type(ESMF_GridComp) :: comp
type(ESMF_State) :: importState, exportState
type(ESMF_Clock) :: clock
integer, intent(out) :: rc

! Initialize return code
rc = ESMF_SUCCESS

print *, "User Comp1 Run"
end subroutine user_run

!-------------------------------------------------- -----------------------
! The Finalization routine
!
subroutine user_final(comp, importState, exportState, clock, rc)
type(ESMF_GridComp) :: comp
type(ESMF_State) :: importState, exportState
type(ESMF_Clock) :: clock
integer, intent(out) :: rc

! Initialize return code
rc = ESMF_SUCCESS

print *, "User Comp1 Final"
end subroutine user_final
end module ESMF_WebServUserModel
The actual driver code then becomes very simple; ESMF is initialized, the component is created, the callback functions for the component are registered, and the Web Service loop is started.

```fortran
program WebServicesEx
  #include "ESMF.h"

  ! ESMF Framework module
  use ESMF
  use ESMF_TestMod

  use ESMF_WebServMod
  use ESMF_WebServUserModel

  implicit none

  ! Local variables
  type(ESMF_GridComp) :: comp1 !! Grid Component
  integer :: rc !! Return Code
  integer :: finalrc !! Final return code
  integer :: portNum !! The port number for the listening socket

  finalrc = ESMF_SUCCESS

  call ESMF_Initialize(defaultlogfilename="WebServicesEx.Log", &
                        logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

  ! create the grid component
  comp1 = ESMF_GridCompCreate(name="My Component", rc=rc)

  ! Set up the register routine
  call ESMF_GridCompSetServices(comp1, &
                                 userRoutine=ESMF_WebServUserModelRegister, rc=rc)

  portNum = 27060

  ! Call the Web Services Loop and wait for requests to come in
  !call ESMF_WebServicesLoop(comp1, portNum, rc=rc)
```

The port number specifies the id of the port on the local machine on which a listening socket will be created. This socket is used by the service to wait for and receive requests from the client. Check with your system administrator to determine an appropriate port to use for your service.

The call to ESMF_WebServicesLoop will setup the listening socket for your service and will wait for requests from a client. As requests are received, the Web Services software will process the requests and then return to the loop to continue to wait.

The 3 main requests processed are INIT, RUN, and FINAL. These requests will then call the appropriate callback routine as specified in your register routine (as specified in the ESMF_GridCompSetServices call). In this example, when the INIT request is received, the user_init routine found in the ESMF_WebServUserModel module is called.
One other request is also processed by the Component Service, and that is the EXIT request. When this request is received, the Web Services loop is terminated and the remainder of the code after the ESMF_WebServicesLoop call is executed.

```fortran
    call ESMF_Finalize(rc=rc)
end program WebServicesEx
```

### 22.3 Restrictions and Future Work

1. **Manual Control of Process.** Currently, the Component Service must be manually started and stopped. Future plans include having the Process Controller be responsible for controlling the Component Service processes.

2. **Data Streaming.** While data can be streamed from the web server to the client, it is not yet getting the data directly from the Component Service. Instead, the Component Service exports the data to a file which the Process Controller can read and return across the network interface. The data streaming capabilities will be a major component of future improvements to the Web Services architecture.

### 22.4 Class API

#### 22.4.1 ESMF_WebServicesLoop

**INTERFACE:**

```fortran
subroutine ESMF_WebServicesLoop(comp, portNum, clientId, registrarHost, rc)
```

**ARGUMENTS:**

- `type(ESMF_GridComp) :: comp`: comp
- `integer, intent(inout), optional :: portNum`
- `character(len=ESMF_MAXSTR), intent(in), optional :: clientId`
- `character(len=ESMF_MAXSTR), intent(in), optional :: registrarHost`
- `integer, intent(out), optional :: rc`

**DESCRIPTION:**

Encapsulates all of the functionality necessary to setup a component as a component service. If this is the root PET, it registers the component service and then enters into a loop that waits for requests on a socket. The loop continues until an "exit" request is received, at which point it exits the loop and unregisters the service. If this is any PET other than the root PET, it sets up a process block that waits for instructions from the root PET. Instructions will come as requests are received from the socket.

The arguments are:
ESMF_CplComp object that represents the Grid Component for which routine is run.

**portNum** Number of the port on which the component service is listening.

**clientId** Identifier of the client responsible for this component service. If a Process Controller application manages this component service, then the clientId is provided to the component service application in the command line. Otherwise, the clientId is not necessary.

**registrarHost** Name of the host on which the Registrar is running. Needed so the component service can notify the Registrar when it is ready to receive requests from clients.

**rc** Return code; equals ESMF_SUCCESS if there are no errors.

---

**22.4.2 ESMF_WebServicesCplCompLoop**

INTERFACE:

```fortran
subroutine ESMF_WebServicesCplCompLoop(comp, portNum, clientId, registrarHost, rc)
```

ARGUMENTS:

```fortran
type(ESMF_CplComp) :: comp
integer, intent(inout), optional :: portNum
character(len=ESMF_MAXSTR), intent(in), optional :: clientId
character(len=ESMF_MAXSTR), intent(in), optional :: registrarHost
integer, intent(out), optional :: rc
```

DESCRIPTION:

Encapsulates all of the functionality necessary to setup a component as a component service. If this is the root PET, it registers the component service and then enters into a loop that waits for requests on a socket. The loop continues until an "exit" request is received, at which point it exits the loop and unregisters the service. If this is any PET other than the root PET, it sets up a process block that waits for instructions from the root PET. Instructions will come as requests are received from the socket.

The arguments are:

**comp** ESMF_CplComp object that represents the Grid Component for which routine is run.

**portNum** Number of the port on which the component service is listening.

**clientId** Identifier of the client responsible for this component service. If a Process Controller application manages this component service, then the clientId is provided to the component service application in the command line. Otherwise, the clientId is not necessary.

**registrarHost** Name of the host on which the Registrar is running. Needed so the component service can notify the Registrar when it is ready to receive requests from clients.

**rc** Return code; equals ESMF_SUCCESS if there are no errors.
Part IV

Infrastructure: Fields and Grids
23 Overview of Data Classes

The ESMF infrastructure data classes are part of the framework’s hierarchy of structures for handling Earth system model data and metadata on parallel platforms. The hierarchy is in complexity; the simplest data class in the infrastructure represents a distributed data array and the most complex data class represents a bundle of physical fields that are discretized on the same grid. Data class methods are called both from user-written code and from other classes internal to the framework.

Data classes are distributed over DEs, or Decomposition Elements. A DE represents a piece of a decomposition. A DELayout is a collection of DEs with some associated connectivity that describes a specific distribution. For example, the distribution of a grid divided into four segments in the x-dimension would be expressed in ESMF as a DELayout with four DEs lying along an x-axis. This abstract concept enables a data decomposition to be defined in terms of threads, MPI processes, virtual decomposition elements, or combinations of these without changes to user code. This is a primary strategy for ensuring optimal performance and portability for codes using ESMF for communications.

ESMF data classes are useful because they provide a standard, convenient way for developers to collect together information related to model or observational data. The information assembled in a data class includes a data pointer, a set of attributes (e.g. units, although attributes can also be user-defined), and a description of an associated grid. The same set of information within an ESMF data object can be used by the framework to arrange intercomponent data transfers, to perform I/O, for communications such as gathers and scatters, for simplification of interfaces within user code, for debugging, and for other functions. This unifies and organizes codes overall so that the user need not define different representations of metadata for the same field for I/O and for component coupling.

Since it is critical that users be able to introduce ESMF into their codes easily and incrementally, ESMF data classes can be created based on native Fortran pointers. Likewise, there are methods for retrieving native Fortran pointers from within ESMF data objects. This allows the user to perform allocations using ESMF, and to retrieve Fortran arrays later for optimized model calculations. The ESMF data classes do not have associated differential operators or other mathematical methods.

For flexibility, it is not necessary to build an ESMF data object all at once. For example, it’s possible to create a field but to defer allocation of the associated field data until a later time.

<table>

<td>A variety of operations are provided for manipulating data in data objects such as regridding, redistribution, halo communication, and sparse matrix multiply.</td>
</tr>
</tbody>
</table>

The main classes that are used for model and observational data manipulation are as follows:

- **Array** An ESMF Array contains a data pointer, information about its associated datatype, precision, and dimension.

  Data elements in Arrays are partitioned into categories defined by the role the data element plays in distributed halo operations. Haloing - sometimes called ghosting - is the practice of copying portions of array data to multiple memory locations to ensure that data dependencies can be satisfied quickly when performing a calculation. ESMF Arrays contain an exclusive domain, which contains data elements updated exclusively and definitively by a given DE; a computational domain, which contains all data elements with values that are updated by the
DE in computations; and a total domain, which includes both the computational domain and data elements from other DEs which may be read but are not updated in computations.

- **ArrayBundle** ArrayBundles are collections of Arrays that are stored in a single object. Unlike FieldBundles, they don’t need to be distributed the same way across PETs. The motivation for ArrayBundles is both convenience and performance.

- **Field** A Field holds model and/or observational data together with its underlying grid or set of spatial locations. It provides methods for configuration, initialization, setting and retrieving data values, data I/O, data regridding, and manipulation of attributes.

- **FieldBundle** Groups of Fields on the same underlying physical grid can be collected into a single object called a FieldBundle. A FieldBundle provides two major functions: it allows groups of Fields to be manipulated using a single identifier, for example during export or import of data between Components; and it allows data from multiple Fields to be packed together in memory for higher locality of reference and ease in subsetting operations. Packing a set of Fields into a single FieldBundle before performing a data communication allows the set to be transferred at once rather than as a Field at a time. This can improve performance on high-latency platforms.

FieldBundle objects contain methods for setting and retrieving constituent fields, regridding, data I/O, and re-ordering of data in memory.

### 23.1 Bit-for-Bit Considerations

Bit-for-bit reproducibility is at the core of the regression testing schemes of many scientific model codes. The bit-for-bit requirement makes it easy to compare the numerical results of simulation runs using standard binary diff tools.

For the most part, ESMF methods do not modify user data numerically, and thus have no effect on the bit-for-bit characteristics of the model code. The exceptions are the regrid weight generation and the sparse matrix multiplication.

In the case of the regrid weight generation, user data is used to produce interpolation weights following specific numerical schemes. The bit-for-bit reproducibility of the generated weights depends on the implementation details. Section 23.2 provides more details about the bit-for-bit considerations with respect to the regrid weights generated by ESMF.

In the case of the sparse matrix multiplication, which is the typical method that is used to apply the regrid weights, user data is directly manipulated by ESMF. In order to help users with the implementation of their bit-for-bit requirements, while also considering the associated performance impact, the ESMF sparse matrix implementation provides three levels of bit-for-bit support. The strictest level ensures that the numerical results are bit-for-bit identical, even when executing across different numbers of PETs. In the relaxed level, bit-for-bit reproducibility is guaranteed when running across an unchanged number of PETs. The lowest level makes no guarantees about bit-for-bit reproducibility, however, it provides the greatest performance potential for those cases where numerical round-off differences are acceptable. An in-depth discussion of bit-for-bit reproducibility, and the performance aspects of route-based communication methods, such as the sparse matrix multiplication, is given in section 35.2.1.

### 23.2 Regrid

This section describes the regridding methods provided by ESMF. Regridding, also called remapping or interpolation, is the process of changing the grid that underlies data values while preserving qualities of the original data. Different kinds of transformations are appropriate for different problems. Regridding may be needed when communicating data between Earth system model components such as land and atmosphere, or between different data sets to support operations such as visualization.
Regridding can be broken into two stages. The first stage is generation of an interpolation weight matrix that describes how points in the source grid contribute to points in the destination grid. The second stage is the multiplication of values on the source grid by the interpolation weight matrix to produce values on the destination grid. This occurs through a parallel sparse matrix multiplication.

There are two options for accessing ESMF regridding functionality: **offline** and **integrated**. Offline regridding is a process whereby interpolation weights are generated by a separate ESMF application, not within the user code. The ESMF offline regridding application also only generates the interpolation matrix, the user is responsible for reading in this matrix and doing the actual interpolation (multiplication by the sparse matrix) in their code. Please see Section 12 for a description of the offline regridding application and the options it supports. For user convenience, there is also a method interface to the offline regrid application functionality which is described in Section 23.3.1. In contrast to offline regridding, integrated regridding is a process whereby interpolation weights are generated via subroutine calls during the execution of the user’s code. In addition to generating the weights, integrated regridding can also produce a `RouteHandle` (described in Section 35.1) which allows the user to perform the parallel sparse matrix multiplication using ESMF methods. In other words, ESMF integrated regridding allows a user to perform the whole process of interpolation within their code.

To see what types of grids and other options are supported in the two types of regridding and their testing status, please see the ESMF Regridding Status webpage for this version of ESMF. Figure 23.3 shows a comparison of different regrid interfaces and where they can be found in the documentation.

The rest of this section further describes various options available in ESMF regridding. It starts with a description of the five interpolation methods available in regridding. Next, it describes how to remove (mask) pieces of a grid from the regridding. Following that, it describes options if a destination point can’t be regridding. After that, is a section on spherical grids and controlling what happens at the pole. Finally, there is a section on troubleshooting regridding.

Table 1: Regrid Interfaces

### 23.2.1 Interpolation methods: bilinear

Bilinear interpolation calculates the value for the destination point as a combination of multiple linear interpolations, one for each dimension of the Grid. Note that for ease of use, the term bilinear interpolation is used for 3D interpolation in ESMF as well, although it should more properly be referred to as trilinear interpolation.

In 2D, ESMF supports bilinear regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of any combination of triangles and quadrilaterals (e.g. rectangles)

In 3D, ESMF supports bilinear regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
Unstructured Meshes composed of hexahedrons (e.g. cubes)

Restrictions:

- Cells which contain enough identical corners to collapse to a line or point are currently ignored
- On a spherical grid, cells which contain an edge which extends more than half way around the sphere are not supported

To use the bilinear method the user may create their Fields on any stagger location (e.g. ESMF_STAGGERLOC_CENTER) for a Grid, or any Mesh location (e.g. ESMF_MESHLOC_NODE) for a Mesh. For either a Grid or a Mesh, the location upon which the Field is built must contain coordinates.

23.2.2 Interpolation methods: higher-order patch

Patch (or higher-order) interpolation is the ESMF version of a technique called “patch recovery” commonly used in finite element modeling [6] [13]. It typically results in better approximations to values and derivatives when compared to bilinear interpolation. Patch interpolation works by constructing multiple polynomial patches to represent the data in a source cell. For 2D grids, these polynomials are currently 2nd degree 2D polynomials. One patch is constructed for each corner of the source cell, and the patch is constructed by doing a least squares fit through the data in the cells surrounding the corner. The interpolated value at the destination point is then a weighted average of the values of the patches at that point. The patch method has a larger stencil than the bilinear, for this reason the patch weight matrix can be correspondingly larger than the bilinear matrix (e.g. for a quadrilateral grid the patch matrix is around 4x the size of the bilinear matrix). This can be an issue when performing a regrid operation close to the memory limit on a machine.

In 2D, ESMF supports patch regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of any combination of triangles and quadrilaterals (e.g. rectangles)

Patch regridding is currently not supported in 3D.

Restrictions:

- Cells which contain enough identical corners to collapse to a line or point are currently ignored
- On a spherical grid, cells which contain an edge which extends more than half way around the sphere are not supported

To use the patch method the user may create their Fields on any stagger location (e.g. ESMF_STAGGERLOC_CENTER) for a Grid, or any Mesh location (e.g. ESMF_MESHLOC_NODE) for a Mesh. For either a Grid or a Mesh, the location upon which the Field is built must contain coordinates.

23.2.3 Interpolation methods: nearest source to destination

In nearest source to destination interpolation (ESMF_REGRIDMETHOD_NEAREST_STOD) each destination point is mapped to the closest source point. A given source point may map to multiple destination points, but no destination...
point will receive input from more than one source point. If two points are equally close, then the point with the smallest sequence index is arbitrarily used (i.e. the point which would have the smallest index in the weight matrix).

In 2D, ESMF supports nearest source to destination regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of any combination of triangles and quadrilaterals (e.g. rectangles)

In 2D, ESMF supports nearest source to destination regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of hexahedrons (e.g. cubes) and tetrahedras

Restrictions:
NONE

To use the nearest source to destination method the user may create their Fields on any stagger location (e.g. ESMF_STAGGERLOC_CENTER) for a Grid, or any Mesh location (e.g. ESMF_MESHLOC_NODE) for a Mesh. For either a Grid or a Mesh, the location upon which the Field is built must contain coordinates.

23.2.4 Interpolation methods: nearest destination to source

In nearest destination to source interpolation (ESMF_REGRIDMETHOD_NEAREST_DTOS) each source point is mapped to the closest destination point. A given destination point may receive input from multiple source points, but no source point will map to more than one destination point. If two points are equally close, then the point with the smallest sequence index is arbitrarily used (i.e. the point which would have the smallest index in the weight matrix). Note, that with this method the unmapped destination point detection currently doesn’t work, so no error will be returned even if there are destination points that don’t map to any source point.

In 2D, ESMF supports nearest destination to source regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of any combination of triangles and quadrilaterals (e.g. rectangles)

In 3D, ESMF supports nearest destination to source regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of hexahedrons (e.g. cubes) and tetrahedras

Restrictions:
NONE

To use the nearest destination to source method the user may create their Fields on any stagger location (e.g. ESMF_STAGGERLOC_CENTER) for a Grid, or any Mesh location (e.g. ESMF_MESHLOC_NODE) for a Mesh. For either a Grid or a Mesh, the location upon which the Field is built must contain coordinates.
23.2.5 Interpolation methods: first-order conservative

First-order conservative interpolation [22] is also available as a regridding method. This method will typically have a larger local interpolation error than the previous two methods, but will do a much better job of preserving the value of the integral of data between the source and destination grid. In this method the value across each source cell is treated as a constant. The weights for a particular destination cell are the area of intersection of each source cell with the destination cell divided by the area of the destination cell. For Cartesian grids, the area of a grid cell is the typical Cartesian area. For grids on a sphere, cell areas are calculated by connecting the corner coordinates of each grid cell with great circles. If the user doesn’t specify cell areas in the involved Grids or Meshes, then the conservation will hold for the areas as calculated by ESMF. This means the following equation will hold: \( \sum_{\text{source-cells}} (V_{si} \times A_{si}) = \sum_{\text{destination-cells}} (V_{dj} \times A'_{dj}) \), where \( V \) is the variable being regridded and \( A' \) is the area of a cell as calculated by ESMF. The subscripts \( s \) and \( d \) refer to source and destination values, and the \( i \) and \( j \) are the source and destination grid cell indices (flattening the arrays to 1 dimension). If the user does specify the areas in the Grid or Mesh, then the conservation will be adjusted to work for the areas provided by the user. This means the following equation will hold: \( \sum_{\text{source-cells}} (V_{si} \times A_{si}) = \sum_{\text{destination-cells}} (V_{dj} \times A_{dj}) \), where \( A \) is the area of a cell as provided by the user.

The user should be aware that because of the conservation relationship between the source and destination fields, the more the total source area differs from the total destination area the more the values of the source field will differ from the corresponding values of the destination field, likely giving a higher interpolation error. It is best to have the total source and destination areas the same (this will automatically be true if no user areas are specified). For source and destination grids that only partially overlap, the overlapping regions of the source and destination should be the same.

Note that for grids on a sphere the conservative interpolation assumes great circle edges to cells. This means that the edges of a cell won’t necessarily be the same as a straight line in latitude longitude. For small edges, this difference will be small, but for long edges it could be significant. This means if the user expects cell edges as straight lines in latitude longitude space, they should avoid using one large cell with long edges to compute an average over a region (e.g. over an ocean basin). The user should also avoid using cells that contain one edge that runs half way or more around the earth, because the regrid weight calculation assumes the edge follows the shorter great circle path. Also, there isn’t a unique great circle edge defined between points on the exact opposite side of the earth from one another (antipodal points). However, the user can work around both of these problem by breaking the long edge into two smaller edges by inserting an extra node, or by breaking the large target grid cells into two or more smaller grid cells. This allows the application to resolve the ambiguity in edge direction.

It is important to note that the current implementation of conservative regridding doesn’t normalize the interpolation weights by the destination fraction. This means that for a destination grid which only partially overlaps the source grid the destination field that is output from the regrid operation should be divided by the corresponding destination fraction to yield the true interpolated values for cells which are only partially covered by the source grid. The fraction also needs to be included when computing the total source and destination integrals.

When a destination field extends outside the unmasked source field, then the values of the cells which extend partway outside the unmasked source field are decreased by the fraction they extend outside. To correct these values, the destination field \( (\text{dst\_field}) \) resulting from the \text{ESMF\_FieldRegrid()} \) call can be divided by the destination fraction \( \text{dst\_frac} \) from the \text{ESMF\_FieldRegridStore()} \) call. The following pseudocode demonstrates how to do this:

```pseudocode
for each destination element i
    if (dst_frac(i) not equal to 0.0) then
        dst_field(i)=dst_field(i)/dst_frac(i)
    end if
end for
```
The following pseudo-code shows how to compute the total destination integral \( \text{dst\_total} \) given the destination field values \( \text{dst\_field} \) resulting from the ESMF_FieldRegrid() call, the destination area \( \text{dst\_area} \) from the ESMF_FieldRegridGetArea() call, and the destination fraction \( \text{dst\_frac} \) from the ESMF_FieldRegridStore() call. As shown in the previous paragraph, it also shows how to adjust the destination field \( \text{dst\_field} \) resulting from the ESMF_FieldRegrid() call by the fraction \( \text{dst\_frac} \) from the ESMF_FieldRegridStore() call:

\[
\text{dst\_total} = 0.0 \\
\text{for each destination element } i \\
\hspace{1em} \text{if } (\text{dst\_frac}(i) \text{ not equal to } 0.0) \text{ then} \\
\hspace{2em} \text{dst\_total} = \text{dst\_total} + \text{dst\_field}(i) \times \text{dst\_area}(i) \\
\hspace{2em} \text{dst\_field}(i) = \text{dst\_field}(i) / \text{dst\_frac}(i) \\
\hspace{2em} \text{If mass computed here after dst\_field adjust, would need to be:} \\
\hspace{3em} \text{dst\_total} = \text{dst\_total} + \text{dst\_field}(i) \times \text{dst\_area}(i) \times \text{dst\_frac}(i) \\
\text{end if} \\
\text{end for}
\]

The following pseudo-code shows how to compute the total source integral \( \text{src\_total} \) given the source field values \( \text{src\_field} \), the source area \( \text{src\_area} \) from the ESMF_FieldRegridGetArea() call, and the source fraction \( \text{src\_frac} \) from the ESMF_FieldRegridStore() call:

\[
\text{src\_total} = 0.0 \\
\text{for each source element } i \\
\hspace{1em} \text{src\_total} = \text{src\_total} + \text{src\_field}(i) \times \text{src\_area}(i) \times \text{src\_frac}(i) \\
\text{end for}
\]

In 2D, ESMF supports conservative regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of any combination of triangles and quadrilaterals (e.g. rectangles)

In 3D, ESMF supports conservative regridding between any combination of the following:

- Structured Grids composed of a single logically rectangular patch
- Unstructured Meshes composed of hexahedrons (e.g. cubes) and tetrahedras

**Restrictions:**

- Concave cells are currently not supported
- Cells which contain enough identical corners to collapse to a line or point are optionally (via a flag) either ignored or return an error
- On a spherical grid, cells which contain an edge which extends more than half way around the sphere are not supported
To use the conservative method the user should create their Fields on the center stagger location (ESMF\_STAGGERLOC\_CENTER in 2D or ESMF\_STAGGERLOC\_CENTER\_VCENTER in 3D) for Grids or the element location (ESMF\_MESHLOC\_ELEMENT) for Meshes. For Grids, the corner stagger location (ESMF\_STAGGERLOC\_CORNER in 2D or ESMF\_STAGGERLOC\_CORNER\_VFACE in 3D) must contain coordinates describing the outer perimeter of the Grid cells.

23.2.6 Masking

Masking is the process whereby parts of a grid can be marked to be ignored during an operation, such as regridding. Masking can be used on a source grid to indicate that certain portions of the grid should not be used to generate regridded data. This is useful, for example, if a portion of source grid contains unusable values. Masking can also be used on a destination grid to indicate that the portion of the field built on that part of the Grid should not receive regridded data. This is useful, for example, when part of the grid isn’t being used (e.g. the land portion of an ocean grid).

ESMF currently supports masking for Fields built on structured Grids and masking for Fields built on unstructured Meshes. The user may mask out points in the source Field or destination Field or both. To do masking the user sets mask information in the Grid (see \[30.3.14\] \footnote{ESMF\_MESHLOC\_ELEMENT} or Mesh (see \[32.3.8\] \footnote{ESMF\_STAGGERLOC\_CORNER\_VFACE} upon which the Fields passed into the ESMF\_FieldRegridStore() call are built. The ‘srcMaskValues’ and ‘dstMaskValues’ arguments to that call can then be used to specify which values in that mask information indicate that a location should be masked out. For example, if ‘dstMaskValues’ is set to (/1,2/), then any location that has a value of 1 or 2 in the mask information of the Grid or Mesh upon which the destination Field is built will be masked out.

Masking behavior differs slightly between regridding methods. For non-conservative regridding methods (e.g. bilinear or high-order patch), masking is done on points. For these methods, masking a destination point means that the point won’t participate in regridding (e.g. won’t be interpolated to). For these methods, masking a source point means that the entire source cell using that point is masked out. In other words, if any corner point making up a source cell is masked then the cell is masked. For conservative regridding methods (e.g. first-order conservative) masking is done on cells. Masking a destination cell means that the cell won’t participate in regridding (e.g. won’t be interpolated to). Similarly, masking a source cell means that the cell won’t participate in regridding (e.g. won’t be interpolated from). For any type of interpolation method (conservative or non-conservative) the masking is set on the location upon which the Fields passed into the regridding call are built. For example, if Fields built on ESMF\_STAGGERLOC\_CENTER are passed into the ESMF\_FieldRegridStore() call then the masking should also be set in ESMF\_STAGGERLOC\_CENTER.

23.2.7 Unmapped destination points

If a destination point can’t be mapped to a location in the source grid, the user has two options. The user may ignore those destination points that can’t be mapped by setting the unmappedaction argument to ESMF\_UNMAPPEDACTION\_IGNORE (Ignored points won’t be included in the sparse matrix or routeHandle). If the user needs the unmapped points, the ESMF\_FieldRegridStore() method has the capability to return a list of them using the unmappedDstList argument. In addition to ignoring them, the user also has the option to return an error if unmapped destination points exist. This is the default behavior, so the user can either not set the unmappedaction argument or the user can set it to ESMF\_UNMAPPEDACTION\_ERROR. At this point ESMF does not support extrapolation to destination points outside the unmasked source Field. Currently, the unmapped destination error detection doesn’t work with the nearest destination to source regrid method (ESMF\_REGRIDMETHOD\_NEAREST\_DTOS), so with this method the regridding behaves as if ESMF\_UNMAPPEDACTION\_IGNORE is always on.
23.2.8 Spherical grids and poles

In the case that the Grid is on a sphere (coordSys=ESMF_COORDSYS_SPH_DEG or ESMF_COORDSYS_SPH_RAD) then the coordinates given in the Grid are interpreted as latitude and longitude values. The coordinates can either be in degrees or radians as indicated by the coordSys flag set during Grid creation. As is true with many global models, this application currently assumes the latitude and longitude refer to positions on a perfect sphere, as opposed to a more complex and accurate representation of the Earth’s true shape such as would be used in a GIS system. (ESMF’s current user base doesn’t require this level of detail in representing the Earth’s shape, but it could be added in the future if necessary.)

For Grids on a sphere, the regridding occurs in 3D Cartesian to avoid problems with periodicity and with the pole singularity. This library supports four options for handling the pole region (i.e. the empty area above the top row of the source grid or below the bottom row of the source grid). Note that all of these pole options currently only work for the Fields build on the Grid class and not for those built on the Mesh class.

The first option is to leave the pole region empty (polemethod=ESMF_POLEMETHOD_NONE), in this case if a destination point lies above or below the top row of the source grid, it will fail to map, yielding an error (unless unmappedaction=ESMF_UNMAPPEDACTION_IGNORE is specified).

With the next two options (ESMF_POLEMETHOD_ALLAVG and ESMF_POLEMETHOD_NPNTAVG), the pole region is handled by constructing an artificial pole in the center of the top and bottom row of grid points and then filling in the region from this pole to the edges of the source grid with triangles. The pole is located at the average of the position of the points surrounding it, but moved outward to be at the same radius as the rest of the points in the grid. The difference between the two artificial pole options is what value is used at the pole. The option (polemethod=ESMF_POLEMETHOD_ALLAVG) sets the value at the pole to be the average of the values of all of the grid points surrounding the pole. The option (polemethod=ESMF_POLEMETHOD_NPNTAVG) allows the user to choose a number N from 1 to the number of source grid points around the pole. The value N is set via the argument regridPoleNPnts. For each destination point, the value at the pole is then the average of the N source points surrounding that destination point.

The last option (polemethod=ESMF_POLEMETHOD_TEETH) does not construct an artificial pole, instead the pole region is covered by connecting points across the top and bottom row of the source Grid into triangles. As this makes the top and bottom of the source sphere flat, for a big enough difference between the size of the source and destination pole regions, this can still result in unmapped destination points. Only pole option ESMF_POLEMETHOD_NONE is currently supported with the conservative interpolation method (regridmethod=ESMF_REGRIDMETHOD_CONSERVE) and with the nearest neighbor interpolation options (regridmethod=ESMF_REGRIDMETHOD_NEAREST_STOD and regridmethod=ESMF_REGRIDMETHOD_NEAREST_DTOS).

Table 2: Line Type Support by Regrid Method (* indicates the default)

Another variation in the regridding supported with spherical grids is line type. This is controlled in the ESMF_FieldRegridStore() method by the lineType argument. This argument allows the user to select the path of the line which connects two points on a sphere surface. This in turn controls the path along which distances...
are calculated and the shape of the edges that make up a cell. Both of these quantities can influence how interpolation weights are calculated, for example in bilinear interpolation the distances are used to calculate the weights and the cell edges are used to determine to which source cell a destination point should be mapped.

ESMF currently supports two line types: ESMF_LINETYPE_CART and ESMF_LINETYPE_GREAT_CIRCLE. The ESMF_LINETYPE_CART option specifies that the line between two points follows a straight path through the 3D Cartesian space in which the sphere is embedded. Distances are measured along this 3D Cartesian line. Under this option cells are approximated by planes in 3D space, and their boundaries are 3D Cartesian lines between their corner points. The ESMF_LINETYPE_GREAT_CIRCLE option specifies that the line between two points follows a great circle path along the sphere surface. (A great circle is the shortest path between two points on a sphere.) Distances are measured along the great circle path. Under this option cells are on the sphere surface, and their boundaries are great circle paths between their corner points.

Figure 23.2.8 shows which line types are supported for each regrid method as well as the defaults (indicated by *).

23.2.9 Troubleshooting guide

The below is a list of problems users commonly encounter with regridding and potential solutions. This is by no means an exhaustive list, so if none of these problems fit your case, or if the solutions don’t fix your problem, please feel free to email esmf support (esmf_support@list.woc.noaa.gov).

Problem: Regridding is too slow.

Possible Cause: The ESMF_FieldRegridStore() method is called more than is necessary. The ESMF_FieldRegridStore() operation is a complex one and can be relatively slow for some cases (large grids, 3D grids, etc.)

Solution: Reduce the number of ESMF_FieldRegridStore() calls to the minimum necessary. The routeHandle generated by the ESMF_FieldRegridStore() call depends on only four factors: the stagger locations that the input Fields are created on, the coordinates in the Grids the input Fields are built on at those stagger locations, the padding of the input Fields (specified by the totalWidth arguments in FieldCreate) and the size of the tensor dimensions in the input Fields (specified by the ungridded arguments in FieldCreate). For any pair of Fields which share these attributes with the Fields used in the ESMF_FieldRegridStore call the same routeHandle can be used. Note, that the data in the Fields does NOT matter, the same routeHandle can be used no matter how the data in the Fields changes.

In particular:

- If Grid coordinates do not change during a run, then the ESMF_FieldRegridStore() call can be done once between a pair of Fields at the beginning and the resulting routeHandle used for each timestep during the run.

- If a pair of Fields was created with exactly the same arguments to ESMF_FieldCreate() as the pair of Fields used during an ESMF_FieldRegridStore() call, then the resulting routeHandle can also be used between that pair of Fields.

Problem: Distortions in destination Field at periodic boundary.

Possible Cause: The Grid overlaps itself. With a periodic Grid, the regrid system expects the first point to not be a repeat of the last point. In other words, regrid constructs its own connection and overlap between the first and last
points of the periodic dimension and so the Grid doesn’t need to contain these. If the Grid does, then this can cause
problems.

**Solution:** Define the Grid so that it doesn’t contain the overlap point. This typically means simply making the Grid
one point smaller in the periodic dimension. If a Field constructed on the Grid needs to contain these overlap points
then the user can use the `totalWidth` arguments to include this extra padding in the Field. Note, however, that the
regrid won’t update these extra points, so the user will have to do a copy to fill the points in the overlap region in the
Field.

23.2.10 Design and implementation notes

The ESMF regrid weight calculation functionality has been designed to enable it to support a wide range of grid and
interpolation types without needing to support each individual combination of source grid type, destination grid type,
and interpolation method. To avoid the quadratic growth of the number of pairs of grid types, all grids are converted
to a common internal format and the regrid weight calculation is performed on that format. This vastly reduces the
variety of grids that need to be supported in the weight calculations for each interpolation method. It also has the added
benefit of making it straightforward to add new grid types and to allow them to work with all the existing grid types.
To hook into the existing weight calculation code, the new type just needs to be converted to the internal format.

The internal grid format used by the ESMF regrid weight calculation is a finite element unstructured mesh. This was
chosen because it was the most general format and all the others could be converted to it. The ESMF finite element
unstructured mesh (ESMF FEM) is similar in some respects to the SIERRA package developed at Sandia National
Laboratory. The ESMF code relies on some of the same underlying toolkits (e.g. Zoltan library for calculating
mesh partitions) and adds a layer on top that allows the calculation of regrid weights and some mesh operations (e.g.
mesh redistribution) that ESMF needs. The ESMF FEM has similar notions to SIERRA about the basic structure of
the mesh entities, fields, iteration and a similar notion of parallel distribution.

Currently we use the ESMF FEM internal mesh to hold the structure of our Mesh class and in our regrid weight
calculation. The parts of the internal FEM code that are used/tested by ESMF are the following:

- The creation of a mesh composed of triangles and quadrilaterals or hexahedrons and tetrahedrons.
- The object relations data base to store the connections between objects (e.g. which element contains which
  nodes).
- The fields to hold data (e.g. coordinates). (We currently only build fields on nodes and elements (2D and 3D).
- Iteration to move through mesh entities.
- The parallel code to maintain information about the distribution of the mesh across processors and to communi-
cate data between parts of the mesh on different processors (i.e. halos).

23.3 File-based Regrid API

23.3.1 ESMF_RegridWeightGen - Generate regrid weight file from grid files

**INTERFACE:**
subroutine ESMF_RegridWeightGenFile(srcFile, dstFile, weightFile, &
regridmethod, polemethod, regridPoleNPnts, &
unmappedaction, srcFileType, dstFileType, &
srcRegionalFlag, dstRegionalFlag, srcMeshname, dstMeshname, &

integer, intent(out), optional :: rc

DESCRIPTION:

This subroutine provides the same function as the ESMF_RegridWeightGen application described in Section 12. It takes two grid files in NetCDF format and writes out an interpolation weight file also in NetCDF format. The interpolation weights can be generated with the bilinear [23.2.1], higher-order patch [23.2.2], or first order conservative [23.2.3] methods. The grid files can be in one of the following four formats:

- The SCRIP format [12.4]
- The native ESMF format for an unstructured grid [12.5]
The GRIDSPEC Tile grid file following the CF metadata convention (12.6). The proposed CF Unstructured grid (UGRID) format (12.7).

The weight file is the same format as is output by SCRIP (12.8). The optional arguments allow users to specify various options to control the regrid operation, such as which pole option to use, whether to use user-specified area in the conservative regridding, or whether ESMF should generate masks using a given variable’s missing value. There are also optional arguments specific to a certain type of the grid file. All the optional arguments are similar to the command line arguments for the ESMF_RegridWeightGen application (12.2). The acceptable values and the default value for the optional arguments are listed below.

The arguments are:

- **srcFile**  The source grid file name.
- **dstFile**  The destination grid file name.
- **weightFile**  The interpolation weight file name.
- **regridmethod**  The type of interpolation. Please see Section 50.43.1 for a list of valid options. If not specified, defaults to ESMF_REGRIDMETHOD_BILINEAR.
- **polemethod**  A flag to indicate which type of artificial pole to construct on the source Grid for regridding. Please see Section 50.41.1 for a list of valid options. The default value varies depending on the regridding method and the grid type and format.
- **regridPoleNPnts**  If polemethod is set to ESMF_POLEMETHOD_NPNTAVG, this argument is required to specify how many points should be averaged over at the pole.
- **unmappedaction**  specify what should happen if there are destination points that can’t be mapped to a source cell. Options are ESMF_UNMAPPEDACTION_ERROR or ESMF_UNMAPPEDACTION_IGNORE. If not specified, defaults to ESMF_UNMAPPEDACTION_ERROR.
- **srcFileType**  The file format of the source grid. Please see Section 30.2.7 and Section 32.2.2 for a list of valid options.
- **dstFileType**  The file format of the destination grid. Please see Section 30.2.7 and Section 32.2.2 for a list of valid options.
- **srcRegionalFlag**  If .TRUE., the source grid is a regional grid, otherwise, it is a global grid. The default value is .FALSE.
- **dstRegionalFlag**  If .TRUE., the destination grid is a regional grid, otherwise, it is a global grid. The default value is .FALSE.
- **srcMeshname**  If the source file is in UGRID format, this argument is required to define the dummy variable name in the grid file that contains the mesh topology info.
- **dstMeshname**  If the destination file is in UGRID format, this argument is required to define the dummy variable name in the grid file that contains the mesh topology info.
- **srcMissingValueFlag**  If .TRUE., the source grid mask will be constructed using the missing values of the variable defined in srcMissingValueVar. This flag is only used for the grid defined in the GRIDSPEC or the UGRID file formats. The default value is .FALSE.
- **srcMissingValueVar**  If srcMissingValueFlag is .TRUE., the argument is required to define the variable name whose missing values will be used to construct the grid mask. It is only used for the grid defined in the GRIDSPEC or the UGRID file formats.
[dstMissingValueFlag] If .TRUE., the destination grid mask will be constructed using the missing values of the variable defined in dstMissingValueVar. This flag is only used for the grid defined in the GRIDSPEC or the UGRID file formats. The default value is .FALSE..

[dstMissingValueVar] If dstMissingValueFlag is .TRUE., the argument is required to define the variable name whose missing values will be used to construct the grid mask. It is only used for the grid defined in the GRIDSPEC or the UGRID file formats.

[useSrcCoordFlag] If .TRUE., the coordinate variables defined in srcCoordinateVars will be used as the longitude and latitude variables for the source grid. This flag is only used for the GRIDSPEC file format. The default is .FALSE.

[srcCoordinateVars] If useSrcCoordFlag is .TRUE., this argument defines the longitude and latitude variables in the source grid file to be used for the regrid. This argument is only used when the grid file is in GRIDSPEC format. srcCoordinateVars should be an array of 2 elements.

[useDstCoordFlag] If .TRUE., the coordinate variables defined in dstCoordinateVars will be used as the longitude and latitude variables for the destination grid. This flag is only used for the GRIDSPEC file format. The default is .FALSE.

[dstCoordinateVars] If useDstCoordFlag is .TRUE., this argument defines the longitude and latitude variables in the destination grid file to be used for the regrid. This argument is only used when the grid file is in GRIDSPEC format. dstCoordinateVars should be an array of 2 elements.

[useUserAreaFlag] If .TRUE., the element area values defined in the grid files are used. Only the SCRIP and ESMF format grid files have user specified areas. This flag is only used for conservative regridding. The default is .FALSE.

[largefileFlag] If .TRUE., the output weight file is in NetCDF 64bit offset format. The default is .FALSE.

[netcdf4fileFlag] If .TRUE., the output weight file is in NetCDF4 file format. The default is .FALSE.

[verboseFlag] If .TRUE., it will print summary information about the regrid parameters, default to .FALSE.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

23.3.2 ESMF_RegridWeightGen - Generate regrid routeHandle and an optional weight file from grid files with user-specified distribution

INTERFACE:

! Private name; call using ESMF_RegridWeightGen()
subroutine ESMF_RegridWeightGenDG(srcFile, dstFile, regridRouteHandle, &
srcElementDistgrid, dstElementDistgrid, &

**DESCRIPTION:**

This subroutine does online regridding weight generation from files with user specified distribution. The main differences between this API with the one in [23.3.1] are as follows:

- The input grids are always represented as ESMF_Mesh whether they are logically rectangular or unstructured.
- The input grids will be decomposed using user-specified distribution instead of a fixed decomposition in the other subroutine if srcElementDistgrid and dstElementDistgrid are specified.
- The source and destination grid files have to be in the SCRIP grid file format.
- This subroutine has one additional required argument regridRouteHandle and four additional optional arguments: srcElementDistgrid, dstElementDistgrid, srcNodalDistgrid and dstNodalDistgrid. These four arguments are of type ESMF_DistGrid, they are used to define the distribution of the source and destination grid elements and nodes. The output regridRouteHandle allows user to regrid the field values later in the application.
- The weightFile argument is optional. When it is given, a weightfile will be generated as well.

The arguments are:

- **srcFile** The source grid file name in SCRIP grid file format
- **dstFile** The destination grid file name in SCRIP grid file format
- **regridRouteHandle** The regrid RouteHandle returned by ESMF_FieldRegridStore()
- **srcElementDistgrid** A optional distGrid that specifies the distribution of the source grid’s elements. If not specified, a system-defined block decomposition is used.
- **dstElementDistgrid** A optional distGrid that specifies the distribution of the destination grid’s elements. If not specified, a system-defined block decomposition is used.
- **weightFile** The interpolation weight file name. If present, an output weight file will be generated.
- **srcNodalDistgrid** An optional distGrid that specifies the distribution of the source grid’s nodes
- **dstNodalDistgrid** An optional distGrid that specifies the distribution of the destination grid’s nodes
[regridmethod] The type of interpolation. Please see Section 50.43.1 for a list of valid options. If not specified, defaults to ESMF_REGRIDMETHOD_BILINEAR.

[unmappedaction] specify what should happen if there are destination points that can’t be mapped to a source cell. Options are ESMF_UNMAPPEDACTION_ERROR or ESMF_UNMAPPEDACTION_IGNORE. If not specified, defaults to ESMF_UNMAPPEDACTION_ERROR.

[useUserAreaFlag] If .TRUE., the element area values defined in the grid files are used. Only the SCRIP and ESMF format grid files have user specified areas. This flag is only used for conservative regridding. The default is .FALSE.

[largefileFlag] If .TRUE., the output weight file is in NetCDF 64bit offset format. The default is .FALSE.

[netcdf4fileFlag] If .TRUE., the output weight file is in NetCDF4 file format. The default is .FALSE.

[verboseFlag] If .TRUE., it will print summary information about the regrid parameters, default to .FALSE.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

23.4 Restrictions and Future Work

1. **32-bit sequence index limitation:** Currently all ESMF interfaces that handle sequence indices for sparse matrix multiplication (SMM) are implemented with default Fortran integer variables, corresponding to a 32-bit signed integer number on all modern architectures. This limits the global data (across PETs) stored in Fields and Arrays, and accessible to SMM, to $2^{31} - 1$ elements. This limitation will be removed in future versions of ESMF by allowing 64-bit sequence indices.
24 FieldBundle Class

24.1 Description

A FieldBundle functions mainly as a convenient container for storing similar Fields. It represents “bundles” of Fields that are discretized on the same Grid, Mesh, LocStream, or XGrid and distributed in the same manner. The FieldBundle is an important data structure because it can be added to a State, which is used for sending and receiving data between Components.

In the common case where FieldBundle is built on top of a Grid, Fields within a FieldBundle may be located at different locations relative to the vertices of their common Grid. The Fields in a FieldBundle may be of different dimensions, as long as the Grid dimensions that are distributed are the same. For example, a surface Field on a distributed lat/lon Grid and a 3D Field with an added vertical dimension on the same distributed lat/lon Grid can be included in the same FieldBundle.

FieldBundles can be created and destroyed, can have Attributes added or retrieved, and can have Fields added, removed, replaced, or retrieved. Methods include queries that return information about the FieldBundle itself and about the Fields that it contains. The Fortran data pointer of a Field within a FieldBundle can be obtained by first retrieving the Field with a call to ESMF_FieldBundleGet(), and then using ESMF_FieldGet() to get the data.

In the future FieldBundles will serve as a mechanism for performance optimization. ESMF will take advantage of the similarities of the Fields within a FieldBundle to optimize collective communication, IO, and regridding. See Section 24.3 for a description of features that are scheduled for future work.

24.2 Use and Examples

Examples of creating, accessing and destroying FieldBundles and their constituent Fields are provided in this section, along with some notes on FieldBundle methods.

24.2.1 Creating a FieldBundle from a list of Fields

A user can create a FieldBundle from a predefined list of Fields. In the following example, we first create an ESMF_Grid, then build 3 different ESMF_Fields with different names. The ESMF_FieldBundle is created from the list of 3 Fields.

```
!---------------------------------------------------
! ! Create several Fields and add them to a new FieldBundle.
! !---------------------------------------------------
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/100,200/), &
      regDecomp=(/2,2/), name="atmgrid", rc=rc)
      ! Call ESMF_ArraySpecSet() to set up the array.
      call ESMF_ArraySpecSet(arrayspec, 2, ESMF_TYPEKIND_R8, rc=rc)
      ! Call ESMF_Finalize() if there is an error.
      if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

field(1) = ESMF_FieldCreate(grid, arrayspec, &
      staggerloc=ESMF_STAGGERLOC_CENTER, &
      name="temperature", rc=rc)
```
field(2) = ESMF_FieldCreate(grid, arrayspec, &
staggerloc=ESMF_STAGGERLOC_CENTER, &
name="pressure", rc=rc)

field(3) = ESMF_FieldCreate(grid, arrayspec, &
staggerloc=ESMF_STAGGERLOC_CENTER, &
name="heat flux", rc=rc)

bundle1 = ESMF_FieldBundleCreate(fieldList=field(1:3), &
 name="atmosphere data", rc=rc)

print *, "FieldBundle example 1 returned"

24.2.2 Creating an empty FieldBundle then add one Field to it

A user can create an empty FieldBundle then add Fields to the empty FieldBundle. In the following example, we use the previously defined ESMF_Grid to build a ESMF_Field. An empty ESMF_FieldBundle is created, then the Field is added to the FieldBundle.

!------------------------------------------------- 
! Create an empty FieldBundle and then add a single field to it.

simplefield = ESMF_FieldCreate(grid, arrayspec, &
staggerloc=ESMF_STAGGERLOC_CENTER, name="rh", rc=rc)

bundle2 = ESMF_FieldBundleCreate(name="time step 1", rc=rc)

call ESMF_FieldBundleAdd(bundle2, (/simplefield/), rc=rc)

call ESMF_FieldBundleGet(bundle2, fieldCount=fieldcount, rc=rc)

print *, "FieldBundle example 2 returned, fieldcount =", fieldcount

24.2.3 Creating an empty FieldBundle then add a list of Fields to it

A user can create an empty FieldBundle then add multiple Fields to the empty FieldBundle. In the following example, we use the previously defined ESMF_Grid and ESMF_Fields. An empty ESMF_FieldBundle is created, then three Fields are added to the FieldBundle.

!------------------------------------------------- 
! Create an empty FieldBundle and then add multiple fields to it.

bundle3 = ESMF_FieldBundleCreate(name="southern hemisphere", rc=rc)
call ESMF_FieldBundleAdd(bundle3, field(1:3), rc=rc)

call ESMF_FieldBundleGet(bundle3, fieldCount=fieldcount, rc=rc)
print *, "FieldBundle example 3 returned, fieldcount =", fieldcount

24.2.4 Query a Field stored in the FieldBundle by name or index

User can query Field stored in a FieldBundle by the Field’s name or index. In the following example, the pressure Field stored in FieldBundle is queried by its name then by its index through ESMF_FieldBundleGet() method.

!---------------------------------------------------------------
! ! Get a Field back from a FieldBundle, first by name and then by index.
! ! Also get the FieldBundle name.
!
call ESMF_FieldBundleGet(bundle1, "pressure", field=returnedfield1, rc=rc)

call ESMF_FieldGet(returnedfield1, name=fname1, rc=rc)

call ESMF_FieldBundleGet(bundle1, 2, returnedfield2, rc=rc)

call ESMF_FieldGet(returnedfield2, name=fname2, rc=rc)

call ESMF_FieldBundleGet(bundle1, name=bname1, rc=rc)

print *, "FieldBundle example 4 returned, field names = ", &
trim(fname1), ", ", trim(fname2)

print *, "FieldBundle name = ", trim(bname1)

24.2.5 Query FieldBundle for Fields list either alphabetical or in order of addition

User can query the list of Fields stored in a FieldBundle. By default the returned list of Fields are ordered alphabetically by the Field names. User can also retrieve the list of Fields by the order the Fields were added to the FieldBundle.

call ESMF_FieldBundleGet(bundle1, fieldList=r_fields, rc=rc)

do i = 1, 3
   call ESMF_FieldGet(r_fields(i), name=fname1, rc=rc)

   print *, fname1
endo
call ESMF_FieldBundleGet(bundle1, fieldList=r_fields, &
   itemorderflag=ESMF_ITEMORDER_ADDORDER, rc=rc)

do i = 1, 3
   call ESMF_FieldGet(r_fields(i), name=fname1, rc=rc)
   print *, fname1
endo

24.2.6 Destroy a FieldBundle

The user must call ESMF_FieldBundleDestroy() before deleting any of the Fields it contains. Because Fields can be shared by multiple FieldBundles and States, they are not deleted by this call.

!--------------------------------------------------
call ESMF_FieldBundleDestroy(bundle1, rc=rc)

24.2.7 Redistribute data from a source FieldBundle to a destination FieldBundle

A user can use ESMF_FieldBundleRedist interface to redistribute data from source FieldBundle to destination FieldBundle. This interface is overloaded by type and kind; In the version of ESMF_FieldBundleRedist without factor argument, a default value of factor 1 is used.

In this example, we first create two FieldBundles, a source FieldBundle and a destination FieldBundle. Then we use ESMF_FieldBundleRedist to redistribute data from source FieldBundle to destination FieldBundle.

! perform redist
   call ESMF_FieldBundleRedistStore(srcFieldBundle, dstFieldBundle, &
      routehandle, rc=rc)

call ESMF_FieldBundleRedist(srcFieldBundle, dstFieldBundle, &
      routehandle, rc=rc)

24.2.8 Perform sparse matrix multiplication from a source FieldBundle to a destination FieldBundle

A user can use ESMF_FieldBundleSMM interface to perform SMM from source FieldBundle to destination FieldBundle. This interface is overloaded by type and kind;

In this example, we first create two FieldBundles, a source FieldBundle and a destination FieldBundle. Then we use ESMF_FieldBundleSMM to perform sparse matrix multiplication from source FieldBundle to destination FieldBundle.

The operation performed in this example is better illustrated in section 26.3.32.

Section 27.2.17 provides a detailed discussion of the sparse matrix multiplication operation implemented in ESMF.
call ESMF_VMGetCurrent(vm, rc=rc)

call ESMF_VMGet(vm, localPet=lpe, rc=rc)

! create distgrid and grid
distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/16/), &
   regDecomp=(/4/), &
   rc=rc)

grid = ESMF_GridCreate(distgrid=distgrid, &
   gridEdgeLWidth=(/0/), gridEdgeUWidth=(/0/), &
   name="grid", rc=rc)

call ESMF_ArraySpecSet(arrayspec, 1, ESMF_TYPEKIND_I4, rc=rc)

! create field bundles and fields
srcFieldBundle = ESMF_FieldBundleCreate(rc=rc)

dstFieldBundle = ESMF_FieldBundleCreate(rc=rc)

do i = 1, 3
   srcField(i) = ESMF_FieldCreate(grid, arrayspec, &
      totalLWidth=(/1/), totalUWidth=(/2/), &
      rc=rc)

   call ESMF_FieldGet(srcField(i), localDe=0, farrayPtr=srcfptr, rc=rc)

   srcfptr = 1
   call ESMF_FieldBundleAdd(srcFieldBundle, (/srcField(i)/), rc=rc)

   dstField(i) = ESMF_FieldCreate(grid, arrayspec, &
      totalLWidth=(/1/), totalUWidth=(/2/), &
      rc=rc)

   call ESMF_FieldGet(dstField(i), localDe=0, farrayPtr=dstfptr, rc=rc)

   dstfptr = 0
   call ESMF_FieldBundleAdd(dstFieldBundle, (/dstField(i)/), rc=rc)
enddo

! initialize factorList and factorIndexList
allocate(factorList(4))
allocate(factorIndexList(2,4))
factorList = (/1,2,3,4/)
factorIndexList(1,:) = (/lpe*4+1,lpe*4+2,lpe*4+3,lpe*4+4/)
factorIndexList(2,:) = (/lpe*4+1,lpe*4+2,lpe*4+3,lpe*4+4/)
call ESMF_FieldBundleSMMStore(srcFieldBundle, dstFieldBundle, &
        routehandle, factorList, factorIndexList, rc=rc)

! perform smm
call ESMF_FieldBundleSMM(srcFieldBundle, dstFieldBundle, routehandle, &
rc=rc)

! release SMM route handle
call ESMF_FieldBundleSMMRelease(routehandle, rc=rc)

24.2.9 Perform FieldBundle halo update

ESMF_FieldBundleHalo interface can be used to perform halo update of all the Fields contained in the ESMF_FieldBundle.

In this example, we will set up a FieldBundle for a 2D inviscid and compressible flow problem. We will illustrate the FieldBundle halo update operation but we will not solve the non-linear PDEs here. The emphasis here is to demonstrate how to set up halo regions, how a numerical scheme updates the exclusive regions, and how halo update communicates data in the halo regions. Here are the governing equations:

\[ u_t + uu_x + vv_y + \frac{1}{\rho} p_x = 0 \] (conservation of momentum in x-direction)

\[ v_t + uv_x + vv_y + \frac{1}{\rho} p_y = 0 \] (conservation of momentum in y-direction)

\[ \rho_t + \rho u_x + \rho v_y = 0 \] (conservation of mass)

\[ \frac{\rho}{\gamma} + u \left( \frac{\rho}{\gamma} \right)_x + v \left( \frac{\rho}{\gamma} \right)_y = 0 \] (conservation of energy)

The four unknowns are pressure \( p \), density \( \rho \), velocity \( (u, v) \). The grids are set up using Arakawa D stagger \( (p \text{ on corner}, \rho \text{ at center}, u \text{ and } v \text{ on edges}) \). \( p, \rho, u, \) and \( v \) are bounded by necessary boundary conditions and initial conditions.

Section 27.2.14 provides a detailed discussion of the halo operation implemented in ESMF.

! create distgrid and grid according to the following decomposition
! and stagger pattern, r is density.
!
! p--------u-------+p+-------u--------p
! !
! !
! ! v r v r v
! ! PET 0 | PET 1 |
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/256,256/), &
regDecomp=(/2,2/), &
rc=rc)

grid = ESMF_GridCreate(distgrid=distgrid, name="grid", rc=rc)

call ESMF_ArraySpecSet(arrayspec, 2, ESMF_TYPEKIND_R4, rc=rc)

! create field bundles and fields
fieldBundle = ESMF_FieldBundleCreate(rc=rc)

! set up exclusive/total region for the fields
!
! halo: L/U, nDim, nField, nPet
! halo configuration for pressure, and similarly for density, u, and v
halo(1,1,1,1) = 0
halo(2,1,1,1) = 0
halo(1,2,1,1) = 0
halo(2,2,1,1) = 0
halo(1,1,1,2) = 1 ! halo in x direction on left hand side of pet 1

            exclusiveLBound=excllb, exclusiveUBound=exclub, rc=rc)
      
      sizes = exclub - excllb
      ! fill the total region with 0.
      fptr = 0.
      ! only update the exclusive region on local PET
      do j = excllb(1), exclub(1)
         do k = excllb(2), exclub(2)
            fptr(j,k) = iter * cos(2.*PI*j/sizes(1)) * sin(2.*PI*k/sizes(2))
         enddo
      endo
      enddo
      call halo execution to update the data in the halo region,
      ! it can be verified that the halo regions change from 0.
      ! to non zero values.
      call ESMF_FieldBundleHalo(fieldbundle, routehandle=routehandle, rc=rc)
endo

! release halo route handle
call ESMF_FieldBundleHaloRelease(routehandle, rc=rc)
24.3 Restrictions and Future Work

1. **No mathematical operators.** The FieldBundle class does not support differential or other mathematical operators. We do not anticipate providing this functionality in the near future.

2. **Limited validation and print options.** We are planning to increase the number of validity checks available for FieldBundles as soon as possible. We also will be working on print options.

3. **Packed data not supported.** One of the options that we are currently working on for FieldBundles is packing. Packing means that the data from all the Fields that comprise the FieldBundle are manipulated collectively. This operation can be done without destroying the original Field data. Packing is being designed to facilitate optimized regridding, data communication, and IO operations. This will reduce the latency overhead of the communication.

4. **Interleaving Fields within a FieldBundle.** Data locality is important for performance on some computing platforms. An interleave option will allow the user to create a packed FieldBundle in which Fields are either concatenated in memory or in which Field elements are interleaved.

24.4 Design and Implementation Notes

1. **Fields in a FieldBundle reference the same Grid, Mesh, LocStream, or XGrid.** In order to reduce memory requirements and ensure consistency, the Fields within a FieldBundle all reference the same Grid, Mesh, LocStream, or XGrid object. This restriction may be relaxed in the future.

24.5 Class API: Basic FieldBundle Methods

24.5.1 ESMF_FieldBundleAssignment(=) - FieldBundle assignment

**INTERFACE:**

```plaintext
interface assignment (=)
fieldbundle1 = fieldbundle2
```

**ARGUMENTS:**

```plaintext
type(ESMF_FieldBundle) :: fieldbundle1
type(ESMF_FieldBundle) :: fieldbundle2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Assign fieldbundle1 as an alias to the same ESMF fieldbundle object in memory as fieldbundle2. If fieldbundle2 is invalid, then fieldbundle1 will be equally invalid after the assignment.

The arguments are:
24.5.2 ESMF_FieldBundleOperator(==) - FieldBundle equality operator

INTERFACE:

```fortran
interface operator(==)
    if (fieldbundle1 == fieldbundle2) then ... endif
    OR
    result = (fieldbundle1 == fieldbundle2)
end interface
```

RETURN VALUE:

```fortran
logical :: result
```

ARGUMENTS:

```fortran
  type(ESMF_FieldBundle), intent(in) :: fieldbundle1
  type(ESMF_FieldBundle), intent(in) :: fieldbundle2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether fieldbundle1 and fieldbundle2 are valid aliases to the same ESMF fieldbundle object in memory. For a more general comparison of two ESMF FieldBundles, going beyond the simple alias test, the ESMF_FieldBundleMatch() function (not yet implemented) must be used.

The arguments are:

- **fieldbundle1** The ESMF_FieldBundle object on the left hand side of the equality operation.
- **fieldbundle2** The ESMF_FieldBundle object on the right hand side of the equality operation.

24.5.3 ESMF_FieldBundleOperator(=/=) - FieldBundle not equal operator

INTERFACE:
interface operator(/=)
  if (fieldbundle1 /= fieldbundle2) then  
  OR
    result = (fieldbundle1 /= fieldbundle2)
  endif

RETURN VALUE:

  logical :: result

ARGUMENTS:

  type(ESMF_FieldBundle), intent(in) :: fieldbundle1
  type(ESMF_FieldBundle), intent(in) :: fieldbundle2

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether fieldbundle1 and fieldbundle2 are not valid aliases to the same ESMF fieldbundle object in memory. For a more general comparison of two ESMF FieldBundles, going beyond the simple alias test, the ESMF_FieldBundleMatch() function (not yet implemented) must be used.

The arguments are:

fieldbundle1  The ESMF_FieldBundle object on the left hand side of the non-equality operation.
fieldbundle2  The ESMF_FieldBundle object on the right hand side of the non-equality operation.

24.5.4  ESMF_FieldBundleAdd - Add Fields to a FieldBundle

INTERFACE:

    ! Private name; call using ESMF_FieldBundleAdd()    
    subroutine ESMF_FieldBundleAddList(fieldbundle, fieldList, &
      multiflag, relaxedflag, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(inout) :: fieldbundle
  type(ESMF_Field), intent(in) :: fieldList(:)
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical, intent(in), optional :: multiflag
  logical, intent(in), optional :: relaxedflag
  integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Add Field(s) to a FieldBundle. It is an error if fieldList contains Fields that match by name Fields already contained in fieldbundle when multiflag is set to .false. and relaxedflag is set to .false..

fieldbundle  ESMF_FieldBundle to be added to.
fieldList   List of ESMF_Field objects to be added.

[multiflag] A setting of .true. allows multiple items with the same name to be added to ESMF_FieldBundle. For .false. added items must have unique names. The default setting is .false..

[relaxedflag] A setting of .true. indicates a relaxed definition of "add" under multiflag=.false. mode, where it is not an error if fieldList contains items with names that are also found in ESMF_FieldBundle. The ESMF_FieldBundle is left unchanged for these items. For .false. this is treated as an error condition. The default setting is .false..

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.5 ESMF_FieldBundleAddReplace - Conditionally add or replace Fields in a FieldBundle

INTERFACE:

subroutine ESMF_FieldBundleAddReplace(fieldbundle, fieldList, rc)

ARGUMENTS:

type(ESMF_FieldBundle), intent(inout) :: fieldbundle
type(ESMF_Field), intent(in) :: fieldList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Fields in fieldList that do not match any Fields by name in fieldbundle are added to the FieldBundle. Fields in fieldList that match any Fields by name in fieldbundle replace those Fields.

fieldbundle  ESMF_FieldBundle to be manipulated.
fieldList  List of ESMF_Field objects to be added or used as replacement.  
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.6 ESMF_FieldBundleCreate - Create a FieldBundle from a list of Fields

INTERFACE:

    function ESMF_FieldBundleCreate(fieldList, &
            multiflag, relaxedflag, name, rc)

RETURN VALUE:

    type(ESMF_FieldBundle) :: ESMF_FieldBundleCreate

ARGUMENTS:

    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Field), intent(in), optional :: fieldList(:)
    logical,                     intent(in), optional :: multiflag
    logical,                     intent(in), optional :: relaxedflag
    character (len=*), intent(in), optional :: name
    integer,                     intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_FieldBundle object from a list of existing Fields.

The creation of a FieldBundle leaves the bundled Fields unchanged, they remain valid individual objects. A FieldBundle is a light weight container of Field references. The actual data remains in place, there are no data movements or duplications associated with the creation of a FieldBundle.

[fieldList]  List of ESMF_Field objects to be bundled.

[multiflag]  A setting of .true. allows multiple items with the same name to be added to fieldbundle. For .false. added items must have unique names. The default setting is .false..

[relaxedflag]  A setting of .true. indicates a relaxed definition of "add" under multiflag=.false. mode, where it is not an error if fieldList contains items with names that are also found in fieldbundle. The fieldbundle is left unchanged for these items. For .false. this is treated as an error condition. The default setting is .false..

[name]  Name of the created ESMF_FieldBundle. A default name is generated if not specified.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
24.5.7 ESMF_FieldBundleDestroy - Release resources associated with a FieldBundle

INTERFACE:

subroutine ESMF_FieldBundleDestroy(fieldbundle, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(inout) :: fieldbundle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroy an ESMF_FieldBundle object. The member Fields are not touched by this operation and remain valid objects that need to be destroyed individually if necessary.

The arguments are:

fieldbundle ESMF_FieldBundle object to be destroyed.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.8 ESMF_FieldBundleGet - Get object-wide information from a FieldBundle

INTERFACE:

! Private name; call using ESMF_FieldBundleGet()
subroutine ESMF_FieldBundleGetListAll(fieldbundle, &
  itemorderflag, geomtype, grid, locstream, mesh, xgrid, &
  fieldCount, fieldList, fieldNameList, name, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(in) :: fieldbundle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_ItemOrder_Flag), intent(in), optional :: itemorderflag
  type(ESMF_GeomType_Flag), intent(out), optional :: geomtype
  type(ESMF_Grid), intent(out), optional :: grid
  type(ESMF_LocStream), intent(out), optional :: locstream
  type(ESMF_Mesh), intent(out), optional :: mesh
type (ESMF_XGrid), intent(out), optional :: xgrid
integer, intent(out), optional :: fieldCount

type (ESMF_Field), intent(out), optional :: fieldList(:)
character(len=*), intent(out), optional :: fieldNameList(:)

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added argument itemorderflag. The new argument gives the user control over the order in which the items are returned.

DESCRIPTION:

Get the list of all Fields and field names bundled in a FieldBundle.

fieldbundle ESMF_FieldBundle to be queried.

[itemorderflag] Specifies the order of the returned items in the fieldList or the fieldNameList. The default is ESMF_ITEMORDER_ABC. See 50.30 for a full list of options.

[geomtype] Flag that indicates what type of geometry this FieldBundle object holds. Can be ESMF_GEOMTYPE_GRID, ESMF_GEOMTYPE_MESH, ESMF_GEOMTYPE_LOCSTREAM, ESMF_GEOMTYPE_XGRID

[grid] The Grid object that this FieldBundle object holds.

[locstream] The LocStream object that this FieldBundle object holds.

[mesh] The Mesh object that this FieldBundle object holds.

[xgrid] The XGrid object that this FieldBundle object holds.

[fieldCount] Upon return holds the number of Fields bundled in the fieldbundle.

[fieldList] Upon return holds a list of Fields bundled in ESMF_FieldBundle. The argument must be allocated to be at least of size fieldCount.

[fieldNameList] Upon return holds a list of the names of the fields bundled in ESMF_FieldBundle. The argument must be allocated to be at least of size fieldCount.

[name] Name of the fieldbundle object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
24.5.9  ESMF_FieldBundleGet - Get information about a Field by name and optionally return a Field

INTERFACE:

! Private name; call using ESMF_FieldBundleGet()
subroutine ESMF_FieldBundleGetItem(fieldbundle, fieldName, &
  field, fieldCount, isPresent, rc)

ARGUMENTS:

type(ESMF_FieldBundle), intent(in) :: fieldbundle
character(len=*) , intent(in) :: fieldName

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Field), intent(out), optional :: field
integer, intent(out), optional :: fieldCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get information about items that match fieldName in FieldBundle.

fieldbundle  ESMF_FieldBundle to be queried.

fieldName  Specified name.

[field]  Upon return holds the requested field item. It is an error if this argument was specified and there is not exactly one field item in ESMF_FieldBundle that matches fieldName.

[fieldCount]  Number of Fields with fieldName in ESMF_FieldBundle.

[isPresent]  Upon return indicates whether field(s) with fieldName exist in ESMF_FieldBundle.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.10  ESMF_FieldBundleGet - Get a list of Fields by name

INTERFACE:

! Private name; call using ESMF_FieldBundleGet()
subroutine ESMF_FieldBundleGetList(fieldbundle, fieldName, fieldList, &
  itemorderflag, rc)
ARGUMENTS:

```
type(ESMF_FieldBundle), intent(in) :: fieldbundle
character(len=*), intent(in) :: fieldName
type(ESMF_Field), intent(out) :: fieldList(:)
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added argument `itemorderflag`. The new argument gives the user control over the order in which the items are returned.

DESCRIPTION:

Get the list of Fields from `fieldbundle` that match `fieldName`.

- `fieldbundle` ESMF_FieldBundle to be queried.
- `fieldName` Specified name.
- `fieldList` List of Fields in ESMF_FieldBundle that match `fieldName`. The argument must be allocated to be at least of size `fieldCount` returned for this `fieldName`.
- `[itemorderflag]` Specifies the order of the returned items in the `fieldList`. The default is ESMF_ITEMORDER_ABC. See Sec 70.30 for a full list of options.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.

24.5.11 ESMF_FieldBundleHalo - Execute a FieldBundle halo operation

INTERFACE:

```
subroutine ESMF_FieldBundleHalo(fieldbundle, routehandle, &
    checkflag, rc)
```

ARGUMENTS:
type(ESMF_FieldBundle), intent(inout) :: fieldbundle

type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
logical, intent(in), optional :: checkflag
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Execute a precomputed FieldBundle halo operation for the Fields in FieldBundle. See ESMF_FieldBundleStore() on how to compute routehandle.

fieldbundle ESMF_FieldBundle with source data. The data in this FieldBundle may be destroyed by this call.
routehandle Handle to the precomputed Route.

[checkflag] If set to .TRUE. the input FieldBundle pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.12 ESMF_FieldBundleHaloRelease - Release resources associated with a FieldBundle halo operation

INTERFACE:

subroutine ESMF_FieldBundleHaloRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a FieldBundle halo operation. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
24.5.13  ESMF_FieldBundleHaloStore - Precompute a FieldBundle halo operation

INTERFACE:

    subroutine ESMF_FieldBundleHaloStore(fieldbundle, routehandle, &
              rc)

ARGUMENTS:

    type(ESMF_FieldBundle), intent(inout) :: fieldbundle
    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a FieldBundle halo operation over the data in fieldbundle. By definition, all elements in the total Field regions that lie outside the exclusive regions will be considered potential destination elements for halo. However, only those elements that have a corresponding halo source element, i.e. an exclusive element on one of the DEs, will be updated under the halo operation. Elements that have no associated source remain unchanged under halo.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldBundleHalo() on any FieldBundle that is weakly congruent and typekind conform to fieldbundle. Congruency for FieldBundles is given by the congruency of its constituents. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

fieldbundle  ESMF_FieldBundle containing data to be haloed. The data in this FieldBundle may be destroyed by this call.

routehandle  Handle to the precomputed Route.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.14  ESMF_FieldBundlePrint - Print FieldBundle information

INTERFACE:

    subroutine ESMF_FieldBundlePrint(fieldbundle, rc)
ARGUMENTS:

```fortran
  type(ESMF_FieldBundle), intent(in)            :: fieldbundle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer,                          intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Print internal information of the specified fieldbundle object.

The arguments are:

- **fieldbundle**: ESMF_FieldBundle object.
- **[rc]**: Return code; equals ESMF_SUCCESS if there are no errors.

24.5.15 ESMF_FieldBundleRead - Read Fields to a FieldBundle from file(s)

INTERFACE:

```fortran
  subroutine ESMF_FieldBundleRead(fieldbundle, file, &
    singleFile, timeslice, iofmt, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_FieldBundle), intent(inout)            :: fieldbundle
  character(*),                               intent(in)            :: file
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical,                         intent(in), optional :: singleFile
  integer,                     intent(in), optional :: timeslice
  type(ESMF_IOFmt_Flag),        intent(in), optional :: iofmt
  integer,                     intent(out), optional :: rc
```

DESCRIPTION:

Read field data to a FieldBundle object from file(s). For this API to be functional, the environment variable ESMF_PIO should be set to "internal" when the ESMF library is built. Please see the section on Data I/O.

Limitations:

- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.
The arguments are:

**fieldbundle**  An ESMF_FieldBundle object.

**file**  The name of the file from which fieldbundle data is read.

**[singleFile]**  A logical flag, the default is .true., i.e., all Fields in the bundle are stored in one single file. If .false., each field is stored in separate files; these files are numbered with the name based on the argument “file”. That is, a set of files are named: [file_name]001, [file_name]002, [file_name]003,...

**[timeslice]**  The time-slice number of the variable read from file.

**[iofmt]**  The IO format. Please see Section 50.2 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 24.5.16  ESMF_FieldBundleRedist - Execute a FieldBundle redistribution

**INTERFACE:**

```fortran
subroutine ESMF_FieldBundleRedist(srcFieldBundle, dstFieldBundle, &
routehandle, checkflag, rc)
```

**ARGUMENTS:**

- type(ESMF_FieldBundle), intent(in), optional :: srcFieldBundle
- type(ESMF_FieldBundle), intent(inout), optional :: dstFieldBundle
- type(ESMF_RouteHandle), intent(inout) :: routehandle
- logical, intent(in), optional :: checkflag
- integer, intent(out), optional :: rc

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Execute a precomputed FieldBundle redistribution from `srcFieldBundle` to `dstFieldBundle`. Both `srcFieldBundle` and `dstFieldBundle` must be weakly congruent and typekind conform with the respective FieldBundles used during `ESMF_FieldBundleRedistStore()`. Congruent FieldBundles possess matching DistGrids and the shape of the local array tiles matches between the FieldBundles for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same `routehandle` can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

The `srcFieldBundle` and `dstFieldBundle` arguments are optional in support of the situation where `srcFieldBundle` and/or `dstFieldBundle` are not defined on all PETs. The `srcFieldBundle` and
dstFieldBundle must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical FieldBundle object for srcFieldBundle and dstFieldBundle arguments.

See ESMF_FieldBundleRedistStore() on how to precompute routehandle.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 24.2.7.

[srcFieldBundle] ESMF_FieldBundle with source data.

[dstFieldBundle] ESMF_FieldBundle with destination data.

routehandle Handle to the precomputed Route.

[checkflag] If set to .TRUE. the input FieldBundle pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

24.5.17 ESMF_FieldBundleRedistRelease - Release resources associated with a FieldBundle redistribution

INTERFACE:

subroutine ESMF_FieldBundleRedistRelease(routehandle, rc)

ARGUMENTS:

  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a FieldBundle redistribution. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
24.5.18 ESMF_FieldBundleRedistStore - Precompute a FieldBundle redistribution with local factor argument

INTERFACE:

! Private name; call using ESMF_FieldBundleRedistStore()
subroutine ESMF_FieldBundleRedistStore<type><kind>(srcFieldBundle, &
          dstFieldBundle, routehandle, factor, &
          srcToDstTransposeMap, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(in) :: srcFieldBundle
  type(ESMF_FieldBundle), intent(inout) :: dstFieldBundle
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  <type>(ESMF_KIND_<kind>), intent(in) :: factor
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: srcToDstTransposeMap(:)
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a FieldBundle redistribution operation from srcFieldBundle to dstFieldBundle. PETs that specify a factor argument must use the <type><kind> overloaded interface. Other PETs call into the interface without factor argument. If multiple PETs specify the factor argument its type and kind as well as its value must match across all PETs. If none of the PETs specifies a factor argument the default will be a factor of 1.

Both srcFieldBundle and dstFieldBundle are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.14 for details on the definition of sequence indices. Redistribution corresponds to an identity mapping of the source FieldBundle vector to the destination FieldBundle vector.

Source and destination FieldBundles may be of different <type><kind>. Further source and destination FieldBundles may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical FieldBundle object for srcFieldBundle and dstFieldBundle arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldBundleRedist() on any pair of FieldBundles that are congruent and typekind conform with the srcFieldBundle, dstFieldBundle pair. Congruent FieldBundles possess matching DistGrids and the shape of the local array tiles matches between the FieldBundles for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.
For examples and associated documentations using this method see Section 24.2.7.

The arguments are:

srcFieldBundle  ESMF_FieldBundle with source data.

dstFieldBundle  ESMF_FieldBundle with destination data. The data in this FieldBundle may be destroyed by this call.

routehandle  Handle to the precomputed Route.

factor  Factor by which to multiply source data.

[srcToDstTransposeMap]  List with as many entries as there are dimensions in srcFieldBundle. Each entry maps the corresponding srcFieldBundle dimension against the specified dstFieldBundle dimension. Mixing of distributed and undistributed dimensions is supported.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.19  ESMF_FieldBundleRedistStore - Precompute a FieldBundle redistribution with local factor argument

INTERFACE:

subroutine ESMF_FieldBundleRedistStoreNF(srcFieldBundle, dstFieldBundle, &
routehandle, factor, srcToDstTransposeMap, rc)

ARGUMENTS:

type(ESMF_FieldBundle), intent(in) :: srcFieldBundle

type(ESMF_FieldBundle), intent(inout) :: dstFieldBundle

type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: srcToDstTransposeMap(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a FieldBundle redistribution operation from srcFieldBundle to dstFieldBundle. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.
Both srcFieldBundle and dstFieldBundle are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices. Redistribution corresponds to an identity mapping of the source FieldBundle vector to the destination FieldBundle vector.

Source and destination Fields may be of different <type><kind>. Further source and destination Fields may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical FieldBundle object for srcFieldBundle and dstFieldBundle arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldBundleRedist() on any pair of Fields that are congruent and typekind conform with the srcFieldBundle, dstFieldBundle pair. Congruent Fields possess matching DistGrids and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 24.2.7.

The arguments are:

srcFieldBundle ESMF_FieldBundle with source data.

dstFieldBundle ESMF_FieldBundle with destination data. The data in this FieldBundle may be destroyed by this call.

routehandle Handle to the precomputed Route.

[srcToDstTransposeMap] List with as many entries as there are dimensions in srcFieldBundle. Each entry maps the corresponding srcFieldBundle dimension against the specified dstFieldBundle dimension. Mixing of distributed and undistributed dimensions is supported.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.20 ESMF_FieldBundleRegrid - Execute a FieldBundle regrid operation

INTERFACE:

subroutine ESMF_FieldBundleRegrid(srcFieldBundle, dstFieldBundle, & routehandle, zeroregion, checkflag, rc)

ARGUMENTS:

type (ESMF_FieldBundle), intent (in),   optional :: srcFieldBundle
type (ESMF_FieldBundle), intent (inout), optional :: dstFieldBundle
type (ESMF_RouteHandle), intent (inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
EXECUTE a precomputed FieldBundle regrid from srcFieldBundle to dstFieldBundle. Both srcFieldBundle and dstFieldBundle must be congruent and typekind conform with the respective FieldBundles used during ESMF_FieldBundleRegridStore(). Congruent FieldBundles possess matching DistGrids and the shape of the local array tiles matches between the FieldBundles for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

The srcFieldBundle and dstFieldBundle arguments are optional in support of the situation where srcFieldBundle and/or dstFieldBundle are not defined on all PETs. The srcFieldBundle and dstFieldBundle must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical FieldBundle object for srcFieldBundle and dstFieldBundle arguments.

See ESMF_FieldBundleRegridStore() on how to precompute routehandle.

This call is collective across the current VM.

[srcFieldBundle] ESMF_FieldBundle with source data.

[dstFieldBundle] ESMF_FieldBundle with destination data.

routehandle Handle to the precomputed Route.

[zeroregion] If set to ESMF_REGION_TOTAL (default) the total regions of all DEs in dstFieldBundle will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to ESMF_REGION_EMPTY the elements in dstFieldBundle will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting zeroregion to ESMF_REGION_SELECT will only zero out those elements in the destination FieldBundle that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.

[checkflag] If set to .TRUE. the input FieldBundle pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
subroutine ESMF_FieldBundleRegridRelease(routehandle, rc)

ARGUMENTS:

  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a FieldBundle regrid operation. After this call routehandle becomes invalid.

routehandle  Handle to the precomputed Route.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.22  ESMF_FieldBundleRegridStore - Precompute a FieldBundle regrid operation

INTERFACE:

subroutine ESMF_FieldBundleRegridStore(srcFieldBundle, dstFieldBundle, &
  srcMaskValues, dstMaskValues, &
  regridmethod, polemethod, &
  regridPoleNPnts, &
  unmappedaction, routehandle, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(in) :: srcFieldBundle
  type(ESMF_FieldBundle), intent(inout) :: dstFieldBundle
  integer(ESMF_KIND_I4), intent(in), optional :: srcMaskValues(:)
  integer(ESMF_KIND_I4), intent(in), optional :: dstMaskValues(:)
  type(ESMF_RegridMethod_Flag), intent(in), optional :: regridmethod
  type(ESMF_PoleMethod_Flag), intent(in), optional :: polemethod
  integer, intent(in), optional :: regridPoleNPnts
  type(ESMF_UnmappedAction_Flag), intent(in), optional :: unmappedaction
  type(ESMF_RouteHandle), intent(inout), optional :: routehandle
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Store a FieldBundle regrid operation over the data in srcFieldBundle and dstFieldBundle pair.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldBundleRegrid() on any FieldBundle pairs that are weakly congruent and typekind conform to the FieldBundle pair used here. Congruency for FieldBundles is given by the congruency of its constituents. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. Note ESMF_FieldBundleRegridStore() assumes the coordinates used in the Grids upon which the FieldBundles are built are in degrees.

This call is collective across the current VM.

srcFieldbundle  Source ESMF_FieldBundle containing data to be regredded.

dstFieldbundle  Destination ESMF_FieldBundle. The data in this FieldBundle may be overwritten by this call.

[srcMaskValues] Mask information can be set in the Grids (see 30.3.14) or Meshes (see 32.3.8) upon which the Fields in the srcFieldbundle are built. The srcMaskValues argument specifies the values in that mask information which indicate a source point should be masked out. In other words, a location is masked if and only if the value for that location in the mask information matches one of the values listed in srcMaskValues. If srcMaskValues is not specified, no masking will occur.

[dstMaskValues] Mask information can be set in the Grids (see 30.3.14) or Meshes (see 32.3.8) upon which the Fields in the dstFieldbundle are built. The dstMaskValues argument specifies the values in that mask information which indicate a destination point should be masked out. In other words, a location is masked if and only if the value for that location in the mask information matches one of the values listed in dstMaskValues. If dstMaskValues is not specified, no masking will occur.

[unmappedaction] Specifies what should happen if there are destination points that can’t be mapped to a source cell. Options are ESMF_UNMAPPEDACTION_ERROR or ESMF_UNMAPPEDACTION_IGNORE. If not specified, defaults to ESMF_UNMAPPEDACTION_ERROR.

[regridmethod] The type of interpolation. Please see Section 50.43.1 for a list of valid options. If not specified, defaults to ESMF_REGRIDMETHOD_BILINEAR.

[polemethod] Which type of artificial pole to construct on the source Grid for regridding. Please see Section 50.41.1 for a list of valid options. If not specified, defaults to ESMF_POLEMETHOD_ALLAVG.

[regridPoleNPnts] If polemethod is ESMF_POLEMETHOD_NPNTAVG. This parameter indicates how many points should be averaged over. Must be specified if polemethod is ESMF_POLEMETHOD_NPNTAVG.

[routehandle] Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.23 ESMF_FieldBundleRemove - Remove Fields from FieldBundle

INTERFACE:

    subroutine ESMF_FieldBundleRemove(fieldbundle, fieldNameList, &
                                          multiflag, relaxedflag, rc)
ARGUMENTS:

```fortran
  type(ESMF_FieldBundle), intent(inout) :: fieldbundle
  character(len=*), intent(in) :: fieldNameList(:)
```

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

```fortran
  logical, intent(in), optional :: multiflag
  logical, intent(in), optional :: relaxedflag
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Remove field(s) by name from FieldBundle. In the relaxed setting it is not an error if fieldNameList contains names that are not found in fieldbundle.

fieldbundle  ESMF_FieldBundle from which to remove items.

fieldNameList  List of items to remove.

[multiflag] A setting of .true. allows multiple Fields with the same name to be removed from fieldbundle. For .false., items to be removed must have unique names. The default setting is .false..

[relaxedflag] A setting of .true. indicates a relaxed definition of "remove" where it is not an error if fieldNameList contains item names that are not found in fieldbundle. For .false. this is treated as an error condition. Further, in multiflag=.false. mode, the relaxed definition of "remove" also covers the case where there are multiple items in fieldbundle that match a single entry in fieldNameList. For relaxedflag=.false. this is treated as an error condition. The default setting is .false..

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.24  ESMF_FieldBundleReplace - Replace Fields in FieldBundle

INTERFACE:

```fortran
  subroutine ESMF_FieldBundleReplace(fieldbundle, fieldList, &
     multiflag, relaxedflag, rc)
ARGUMENTS:

  type(ESMF_FieldBundle), intent(inout) :: fieldbundle
  type(ESMF_Field), intent(in) :: fieldList(:)
```

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

```fortran
  logical, intent(in), optional :: multiflag
  logical, intent(in), optional :: relaxedflag
  integer, intent(out), optional :: rc
```
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Replace field(s) by name in FieldBundle. In the relaxed setting it is not an error if fieldList contains Fields that do not match by name any item in fieldbundle. These Fields are simply ignored in this case.

*fieldbundle*  ESMF.getFieldBundle in which to replace items.

*fieldList*  List of items to replace.

**[multiflag]** A setting of .true. allows multiple items with the same name to be replaced in fieldbundle. For .false., items to be replaced must have unique names. The default setting is .false..

**[relaxedflag]** A setting of .true. indicates a relaxed definition of "replace" where it is not an error if fieldList contains items with names that are not found in fieldbundle. These items in fieldList are ignored in the relaxed mode. For .false. this is treated as an error condition. Further, in multiflag=.false. mode, the relaxed definition of "replace" also covers the case where there are multiple items in fieldbundle that match a single entry by name in fieldList. For relaxedflag=.false. this is treated as an error condition. The default setting is .false..

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

24.5.25  ESMF_FieldBundleSet - Associate a Grid with an empty FieldBundle

INTERFACE:

```fortran
! Private name; call using ESMF_FieldBundleSet()
subroutine ESMF_FieldBundleSetGrid(fieldbundle, grid, rc)
```

ARGUMENTS:

- type(ESMF_FieldBundle), intent(inout) :: fieldbundle
- type(ESMF_Grid), intent(in) :: grid
- integer, intent(out), optional :: rc

DESCRIPTION:

Sets the grid for a fieldbundle.

The arguments are:

*fieldbundle*  An ESMF_FieldBundle object.

*grid*  The ESMF_Grid which all ESMF_Fields added to this ESMF_FieldBundle must have.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
24.5.26  ESMF_FieldBundleSet - Associate a Mesh with an empty FieldBundle

INTERFACE:

    ! Private name; call using ESMF_FieldBundleSet()
    subroutine ESMF_FieldBundleSetMesh(fieldbundle, mesh, rc)

ARGUMENTS:

    type(ESMF_FieldBundle), intent(inout) :: fieldbundle
    type(ESMF_Mesh), intent(in) :: mesh
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

DESCRIPTION:

Sets the mesh for a fieldbundle.

The arguments are:

fieldbundle  An ESMF_FieldBundle object.

mesh  The ESMF_Mesh which all ESMF_Fields added to this ESMF_FieldBundle must have.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.27  ESMF_FieldBundleSet - Associate a LocStream with an empty FieldBundle

INTERFACE:

    ! Private name; call using ESMF_FieldBundleSet()
    subroutine ESMF_FieldBundleSetLS(fieldbundle, locstream, &
    rc)

ARGUMENTS:

    type(ESMF_FieldBundle), intent(inout) :: fieldbundle
    type(ESMF_LocStream), intent(in) :: locstream
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

DESCRIPTION:

Sets the locstream for a fieldbundle.

The arguments are:
fieldbundle  An ESMF_FieldBundle object.
locstream  The ESMF_LocStream which all ESMF_Fields added to this ESMF_FieldBundle must have.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.28  ESMF_FieldBundleSet - Associate a XGrid with an empty FieldBundle

INTERFACE:

! Private name; call using ESMF_FieldBundleSet()
subroutine ESMF_FieldBundleSetXGrid(fieldbundle, xgrid, &
   rc)

ARGUMENTS:

   type(ESMF_FieldBundle), intent(inout)   :: fieldbundle
   type(ESMF_XGrid),    intent(in)        :: xgrid

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer,            intent(out), optional :: rc

DESCRIPTION:

Sets the xgrid for a fieldbundle

The arguments are:

fieldbundle  An ESMF_FieldBundle object.
xgrid  The ESMF_XGrid which all ESMF_Fields added to this ESMF_FieldBundle must have.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

24.5.29  ESMF_FieldBundleSMM - Execute a FieldBundle sparse matrix multiplication

INTERFACE:

   subroutine ESMF_FieldBundleSMM(srcFieldBundle, dstFieldBundle, &
       routehandle, zeroregion, checkflag, rc)

ARGUMENTS:

   type(ESMF_FieldBundle), intent(in),   optional :: srcFieldBundle
   type(ESMF_FieldBundle), intent(inout), optional :: dstFieldBundle
   type(ESMF_RouteHandle), intent(inout)   :: routehandle
The following arguments require argument keyword syntax (e.g. rc=rc).

```plaintext
type(ESMF_Region_Flag), intent(in), optional :: zeroregion
logical,       intent(in), optional :: checkflag
integer,       intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Execute a precomputed FieldBundle sparse matrix multiplication from `srcFieldBundle` to `dstFieldBundle`. Both `srcFieldBundle` and `dstFieldBundle` must be congruent and typekind conform with the respective FieldBundles used during `ESMF_FieldBundleSMMStore()`. Congruent FieldBundles possess matching Dist-Grids and the shape of the local array tiles matches between the FieldBundles for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same `routehandle` can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

The `srcFieldBundle` and `dstFieldBundle` arguments are optional in support of the situation where `srcFieldBundle` and/or `dstFieldBundle` are not defined on all PETs. The `srcFieldBundle` and `dstFieldBundle` must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical `FieldBundle` object for `srcFieldBundle` and `dstFieldBundle` arguments.

See `ESMF_FieldBundleSMMStore()` on how to precompute `routehandle`. This call is *collective* across the current VM.

For examples and associated documentations using this method see Section 24.2.8.

- **[srcFieldBundle]** ESMF_FieldBundle with source data.
- **[dstFieldBundle]** ESMF_FieldBundle with destination data.
- **routehandle** Handle to the precomputed Route.
- **[zeroregion]** If set to `ESMF_REGION_TOTAL` ([default]) the total regions of all DEs in `dstFieldBundle` will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to `ESMF_REGION_EMPTY` the elements in `dstFieldBundle` will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting `zeroregion` to `ESMF_REGION_SELECT` will only zero out those elements in the destination FieldBundle that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.
- **[checkflag]** If set to .TRUE. the input FieldBundle pair will be checked for consistency with the precomputed operation provided by `routehandle`. If set to .FALSE. ([default]) only a very basic input check will be performed, leaving many inconsistencies undetected. Set `checkflag` to .FALSE. to achieve highest performance.
- **[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.
24.5.30 ESMF_FieldBundleSMMRelease - Release resources associated with a FieldBundle sparse matrix multiplication

INTERFACE:

subroutine ESMF_FieldBundleSMMRelease(routehandle, rc)

ARGUMENTS:

  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a FieldBundle sparse matrix multiplication. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.31 ESMF_FieldBundleSMMStore - Precompute a FieldBundle sparse matrix multiplication with local factors

INTERFACE:

! Private name; call using ESMF_FieldBundleSMMStore()
subroutine ESMF_FieldBundleSMMStore<type><kind>(srcFieldBundle, &
   dstFieldBundle, routehandle, factorList, factorIndexList, &
   rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(in) :: srcFieldBundle
  type(ESMF_FieldBundle), intent(inout) :: dstFieldBundle
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  <type>(ESMF_KIND_<kind>), intent(in) :: factorList(:)
  integer, intent(in), :: factorIndexList(:,:)
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a FieldBundle sparse matrix multiplication operation from srcFieldBundle to dstFieldBundle. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

Both srcFieldBundle and dstFieldBundle are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices. SMM corresponds to an identity mapping of the source FieldBundle vector to the destination FieldBundle vector.

Source and destination Fields may be of different <type><kind>. Further source and destination Fields may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical FieldBundle object for srcFieldBundle and dstFieldBundle arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldBundleSMM() on any pair of FieldBundles that are congruent and typekind conform with the srcFieldBundle, dstFieldBundle pair. Congruent FieldBundles possess matching DistGrids and the shape of the local array tiles matches between the FieldBundles for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 24.2.8.

The arguments are:

srcFieldBundle ESMF_FieldBundle with source data.
dstFieldBundle ESMF_FieldBundle with destination data. The data in this FieldBundle may be destroyed by this call.
routehandle Handle to the precomputed Route.
factorList List of non-zero coefficients.
factorIndexList Pairs of sequence indices for the factors stored in factorList.

The second dimension of factorIndexList steps through the list of pairs, i.e. size(factorIndexList,2) == size(factorList). The first dimension of factorIndexList is either of size 2 or size 4.

In the size 2 format factorIndexList(1,:) specifies the sequence index of the source element in the srcFieldBundle while factorIndexList(2,:) specifies the sequence index of the destination element in dstFieldBundle. For this format to be a valid option source and destination FieldBundles must
have matching number of tensor elements (the product of the sizes of all Field tensor dimensions). Under this condition an identity matrix can be applied within the space of tensor elements for each sparse matrix factor.

The size 4 format is more general and does not require a matching tensor element count. Here the factorIndexList(1,:) specifies the sequence index while factorIndexList(2,:) specifies the tensor sequence index of the source element in the srcFieldBundle. Further factorIndexList(3,:) specifies the sequence index and factorIndexList(4,:) specifies the tensor sequence index of the destination element in the dstFieldBundle.

See section 27.2.17 for details on the definition of sequence indices and tensor sequence indices.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

24.5.32 ESMF_FieldBundleSMMStore - Precompute a FieldBundle sparse matrix multiplication without local factors

INTERFACE:

! Private name; call using ESMF_FieldBundleSMMStore()
subroutine ESMF_FieldBundleSMMStoreNF(srcFieldBundle, dstFieldBundle, &
  routehandle, rc)

ARGUMENTS:

type(ESMF_FieldBundle), intent(in) :: srcFieldBundle

type(ESMF_FieldBundle), intent(inout) :: dstFieldBundle

type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a FieldBundle sparse matrix multiplication operation from srcFieldBundle to dstFieldBundle. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

Both srcFieldBundle and dstFieldBundle are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices. SMM corresponds to an identity mapping of the source FieldBundle vector to the destination FieldBundle vector.
Source and destination Fields may be of different \texttt{<type><kind>}. Further source and destination Fields may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical FieldBundle object for \texttt{srcFieldBundle} and \texttt{dstFieldBundle} arguments.

The routine returns an \texttt{ESMF_RouteHandle} that can be used to call \texttt{ESMF_FieldBundleSMM()} on any pair of FieldBundles that are congruent and type\texttt{kind} conform with the \texttt{srcFieldBundle}, \texttt{dstFieldBundle} pair. Congruent FieldBundles possess matching DistGrids and the shape of the local array tiles matches between the FieldBundles for every \texttt{DE}. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same \texttt{routehandle} can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for \texttt{ESMF\_TYPEKIND\_I4}, \texttt{ESMF\_TYPEKIND\_I8}, \texttt{ESMF\_TYPEKIND\_R4}, \texttt{ESMF\_TYPEKIND\_R8}.

This call is collective across the current VM.

For examples and associated documentations using this method see Section \ref{sec:24.2.8}.

The arguments are:

\textbf{\texttt{srcFieldBundle}} ESMF\_FieldBundle with source data.

\textbf{\texttt{dstFieldBundle}} ESMF\_FieldBundle with destination data. The data in this FieldBundle may be destroyed by this call.

\textbf{\texttt{routehandle}} Handle to the precomputed Route.

\textbf{\texttt{[rc]}} Return code; equals \texttt{ESMF\_SUCCESS} if there are no errors.

\section*{24.5.33 ESMF\_FieldBundleValidate - Validate fieldbundle internals}

\textbf{INTERFACE:}

\begin{verbatim}
subroutine ESMF_FieldBundleValidate(fieldbundle, rc)

ARGUMENTS:

  type (ESMF\_FieldBundle), intent (in) :: fieldbundle
  integer, intent (out), optional :: rc

DESCRIPTION:

Validates that the \texttt{fieldbundle} is internally consistent. The method returns an error code if problems are found. The arguments are:

\textbf{\texttt{fieldbundle}} Specified ESMF\_FieldBundle object.

\textbf{\texttt{[rc]}} Return code; equals \texttt{ESMF\_SUCCESS} if there are no errors.

\end{verbatim}
24.5.34  ESMF_FieldBundleWrite - Write the Fields into a file

INTERFACE:

subroutine ESMF_FieldBundleWrite(fieldbundle, file, &
   singleFile, overwrite, status, timeslice, iofmt, rc)

ARGUMENTS:

   type(ESMF_FieldBundle),       intent(in)       :: fieldbundle
   character(*) ,               intent(in)       :: file
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
   logical,                     intent(in), optional :: singleFile
   logical,                     intent(in), optional :: overwrite
   type(ESMF_FileStatus_Flag),   intent(in), optional :: status
   integer,                     intent(in), optional :: timeslice
   type(ESMF_IOFmt_Flag),       intent(in), optional :: iofmt
   integer,                     intent(out), optional :: rc

DESCRIPTION:

Write the Fields into a file. For this API to be functional, the environment variable ESMF_PIO should be set to "internal" when the ESMF library is built. Please see the section on Data I/O.[56.3]

Limitations:

- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

fieldbundle  An ESMF_FieldBundle object.

file  The name of the output file to which field bundle data is written.

[singleFile] A logical flag, the default is .true., i.e., all fields in the bundle are written in one single file. If .false., each field will be written in separate files; these files are numbered with the name based on the argument "file". That is, a set of files are named: [file_name]001, [file_name]002, [file_name]003,...

[overwrite] A logical flag, the default is .false., i.e., existing field data may not be overwritten. If .true., the overwrite behavior depends on the value of iofmt as shown below:

iofmt = ESMF_IOFMT_BIN:  All data in the file will be overwritten with each field’s data.

iofmt = ESMF_IOFMT_NETCDF: Only the data corresponding to each field’s name will be overwitten. If the timeslice option is given, only data for the given timeslice may be overwritten. Note that it is always an error to attempt to overwrite a NetCDF variable with data which has a different shape.

[status] The file status. Please see Section [50.19] for the list of options. If not present, defaults to ESMF_FILESTATUS_UNKNOWN.

[timeslice] Some IO formats (e.g. NetCDF) support the output of data in form of time slices. The timeslice argument provides access to this capability. timeslice must be positive. The behavior of this option may depend on the setting of the overwrite flag:
overwrite = .false.: If the timeslice value is less than the maximum time already in the file, the write will fail.
overwrite = .true.: Any positive timeslice value is valid.

By default, i.e. by omitting the timeslice argument, no provisions for time slicing are made in the output file, however, if the file already contains a time axis for the variable, a timeslice one greater than the maximum will be written.

[iofmt] The IO format. Please see Section 50.26 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25 Field Class

25.1 Description

An ESMF Field represents a physical field, such as temperature. The motivation for including Fields in ESMF is that bundles of Fields are the entities that are normally exchanged when coupling Components.

The ESMF Field class contains distributed and discretized field data, a reference to its associated grid, and metadata. The Field class stores the grid staggering for that physical field. This is the relationship of how the data array of a field maps onto a grid (e.g. one item per cell located at the cell center, one item per cell located at the NW corner, one item per cell vertex, etc.). This means that different Fields which are on the same underlying ESMF Grid but have different staggerings can share the same Grid object without needing to replicate it multiple times.

Fields can be added to States for use in inter-Component data communications. Fields can also be added to FieldBundles, which are groups of Fields on the same underlying Grid. One motivation for packing Fields into FieldBundles is convenience; another is the ability to perform optimized collective data transfers.

Field communication capabilities include: data redistribution, regridding, scatter, gather, sparse-matrix multiplication, and halo update. These are discussed in more detail in the documentation for the specific method calls. ESMF does not currently support vector fields, so the components of a vector field must be stored as separate Field objects.

25.1.1 Operations

The Field class allows the user to easily perform a number of operations on the data stored in a Field. This section gives a brief summary of the different types of operations and the range of their capabilities. The operations covered here are: redistribution (ESMF_FieldRedistStore()), sparse matrix multiply (ESMF_FieldSMMStore()), and regridding (ESMF_FieldRegridStore()).

The redistribution operation (ESMF_FieldRedistStore()) allows the user to move data between two Fields with the same size, but different distribution. This operation is useful, for example, to move data between two components with different distributions. Please see Section 25.3.29 for an example of the redistribution capability.

The sparse matrix multiply operation (ESMF_FieldSMMStore()) allows the user to multiply the data in a Field by a sparse matrix. This operation is useful, for example, if the user has an interpolation matrix and wants to apply it to the data in a Field. Please see Section 25.3.32 for an example of the sparse matrix multiply capability.

The regridding operation (ESMF_FieldRegridStore()) allows the user to move data from one grid to another while maintaining certain properties of the data. Regridding is also called interpolation or remapping. In the Field regridding operation the grids the data is being moved between are the grids associated with the Fields storing the data.
The regridding operation works on Fields built on 2D or 3D Mes hes and 2D or 3D Grids. There are three regridding methods available: bilinear, higher-order patch, and first-order conservative. All three of these methods are supported on 2D Grids or 2D Mes hes. In 3D the situation is more complicated. Bilinear is supported on 3D Grid or 3D Mes hes composed of hexahedrons. Higher-order patch is not supported in 3D. First-order conservative is supported on 3D Grids or 3D Mes hes composed of hexahedrons or tetrahedrons. There are also a range of options for what to do at the poles and what to do if a point does not map. Please see Section 25.3.24 for a full description of the regridding capability. Several sections following Section 25.3.24 contain examples of using regridding.

25.2 Constants

25.2.1 ESMF_FIELDSTATUS

DESCRIPTION:

An ESMF_Field can be in different status after initialization. Field status can be queried using ESMF_FieldGet() method.

The type of this flag is:

type (ESMF_FieldStatus_Flag)

The valid values are:

ESMF_FIELDSTATUS_EMPTY Field is empty without geombase or data storage. Such a Field can be added to a ESMF_State and participate ESMF_StateReconcile().

ESMF_FIELDSTATUS_GRIDSET Field is partially created. It has a geombase object internally created and the geombase object associates with either a ESMF_Grid, or a ESMF_Mesh, or an ESMF_XGrid, or a ESMF_LocStream. It’s an error to set another geombase object in such a Field. It can also be added to a ESMF_State and participate ESMF_StateReconcile().

ESMF_FIELDSTATUS_COMPLETE Field is completely created with geombase and data storage internally allocated.

25.3 Use and Examples

A Field serves as an annotator of data, since it carries a description of the grid it is associated with and metadata such as name and units. Fields can be used in this capacity alone, as convenient, descriptive containers into which arrays can be placed and retrieved. However, for most codes the primary use of Fields is in the context of import and export States, which are the objects that carry coupling information between Components. Fields enable data to be self-describing, and a State holding ESMF Fields contains data in a standard format that can be queried and manipulated.

The sections below go into more detail about Field usage.

25.3.1 Field create and destroy

Fields can be created and destroyed at any time during application execution. However, these Field methods require some time to complete. We do not recommend that the user create or destroy Fields inside performance-critical computational loops.
All versions of the ESMF_FieldCreate() routines require a Grid object as input, or require a Grid be added before most operations involving Fields can be performed. The Grid contains the information needed to know which Decomposition Elements (DEs) are participating in the processing of this Field, and which subsets of the data are local to a particular DE.

The details of how the create process happens depends on which of the variants of the ESMF_FieldCreate() call is used. Some of the variants are discussed below.

There are versions of the ESMF_FieldCreate() interface which create the Field based on the input Grid. The ESMF can allocate the proper amount of space but not assign initial values. The user code can then get the pointer to the uninitialized buffer and set the initial data values.

Other versions of the ESMF_FieldCreate() interface allow user code to attach arrays that have already been allocated by the user. Empty Fields can also be created in which case the data can be added at some later time.

For versions of Create which do not specify data values, user code can create an ArraySpec object, which contains information about the typekind and rank of the data values in the array. Then at Field create time, the appropriate amount of memory is allocated to contain the data which is local to each DE.

When finished with a ESMF_Field, the ESMF_FieldDestroy method removes it. However, the objects inside the ESMF_Field created externally should be destroyed separately, since objects can be added to more than one ESMF_Field. For example, the same ESMF_Grid can be referenced by multiple ESMF_Fields. In this case the internal Grid is not deleted by the ESMF_FieldDestroy call.

### 25.3.2 Get Fortran data pointer, bounds, and counts information from a Field

A user can get bounds and counts information from an ESMF_Field through the ESMF_FieldGet() interface. Also available through this interface is the intrinsic Fortran data pointer contained in the internal ESMF_Array object of an ESMF_Field. The bounds and counts information are DE specific for the associated Fortran data pointer.

For a better discussion of the terminologies, bounds and widths in ESMF e.g. exclusive, computational, total bounds for the lower and upper corner of data region, etc., user can refer to the explanation of these concepts for Grid and Array in their respective sections in the Reference Manual, e.g. Section 27.2.6 on Array and Section 30.3.16 on Grid.

In this example, we first create a 3D Field based on a 3D Grid and Array. Then we use the ESMF_FieldGet() interface to retrieve the data pointer, potentially updating or verifying its values. We also retrieve the bounds and counts information of the 3D Field to assist in data element iteration.

```fortran
xdim = 180
ydim = 90
zdim = 50

! create a 3D data Field from a Grid and Array.
! first create a Grid
grid3d = ESMF_GridCreateNoPeriDim(minIndex=(/1,1,1/), &
                           maxIndex=(/xdim,ydim,zdim/), &
                           regDecomp=(/2,2,1/), name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_GridGet(grid=grid3d, staggerloc=ESMF_STAGGERLOC_CENTER, &
                   distgrid=distgrid3d, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_GridGetFieldBounds(grid=grid3d, localDe=0, &
                             staggerloc=ESMF_STAGGERLOC_CENTER, totalCount=fa_shape, rc=rc)
```
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

allocate(farray(fa_shape(1), fa_shape(2), fa_shape(3)) )

! create an Array
array3d = ESMF_ArrayCreate(distgrid3d, farray, &
indexflag=ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create a Field
field = ESMF_FieldCreate(grid=grid3d, array=array3d, rc =rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! retrieve the Fortran data pointer from the Field
call ESMF_FieldGet(field=field, localDe=0, farrayPtr=farray1, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! retrieve the Fortran data pointer from the Field and bounds
call ESMF_FieldGet(field=field, localDe=0, farrayPtr=farray1, &
computationalLBound=compLBnd, computationalUBound=compUBnd, &
exclusiveLBound=exclLBnd, exclusiveUBound=exclUBnd, &
totalLBound=totalLBnd, totalUBound=totalUBnd, &
computationalCount=comp_count, &
exclusiveCount=excl_count, &
totalCount=total_count, &
rc=rc)

! iterate through the total bounds of the field data pointer
do k = totalLBnd(3), totalUBnd(3)
do j = totalLBnd(2), totalUBnd(2)
do i = totalLBnd(1), totalUBnd(1)
   farray1(i, j, k) = sin(2*i/total_count(1)*PI) + &
   sin(4*j/total_count(2)*PI) + &
   sin(8*k/total_count(2)*PI)
endo
endo
endo

25.3.3 Get Grid, Array, and other information from a Field

A user can get the internal ESMF_Grid and ESMF_Array from a ESMF_Field. Note that the user should not issue any destroy command on the retrieved grid or array object since they are referenced from within the ESMF_Field. The retrieved objects should be used in a read-only fashion to query additional information not directly available through the ESMF_FieldGet() interface.

call ESMF_FieldGet(field, grid=grid, array=array, &
typekind=typekind, dimCount=dimCount, staggerloc=staggerloc, &
gridToFieldMap=gridToFieldMap, &
ungriddedLBound=ungriddedLBound, ungriddedUBound=ungriddedUBound, &
totalLWidth=totalLWidth, totalUWidth=totalUWidth, &
name=name, &
rc=rc)
25.3.4 Create a Field with a Grid, typekind, and rank

A user can create an ESMF_Field from an ESMF_Grid and typekind/rank. This create method associates the two objects.

We first create a Grid with a regular distribution that is 10x20 index in 2x2 DEs. This version of Field create simply associates the data with the Grid. The data is referenced explicitly on a regular 2x2 uniform grid. Finally we create a Field from the Grid, typekind, rank, and a user specified StaggerLoc.

This example also illustrates a typical use of this Field creation method. By creating a Field from a Grid and typekind/rank, the user allows the ESMF library to create an internal Array in the Field. Then the user can use ESMF_FieldGet() to retrieve the Fortran data array and necessary bounds information to assign initial values to it.

```fortran
! create a grid
grid = ESMF_GridCreateNoPeriDim(minIndex= (/1,1/), maxIndex= (/10,20/), &
   regDecomp= (/2,2/), name= "atmgrid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create a Field from the Grid and arrayspec
field1 = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_R4, &
   indexflag=ESMF_INDEX_DELOCAL, &
   staggerloc=ESMF_STAGGERLOC_CENTER, name= "pressure", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_FieldGet(field1, localDe=0, farrayPtr=farray2dd, &
   totalLBound=ftlb, totalUBound=ftub, totalCount=ftc, rc=rc)
do i = ftlb(1), ftub(1)
do j = ftlb(2), ftub(2)
   farray2dd(i, j) = sin(i/ftc(1)*PI) * cos(j/ftc(2)*PI)
enddo
enddo
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

25.3.5 Create a Field with a Grid and Arrayspec

A user can create an ESMF_Field from an ESMF_Grid and an ESMF_Arrayspec with corresponding rank and type. This create method associates the two objects.

We first create a Grid with a regular distribution that is 10x20 index in 2x2 DEs. This version of Field create simply associates the data with the Grid. The data is referenced explicitly on a regular 2x2 uniform grid. Then we create an ArraySpec. Finally we create a Field from the Grid, ArraySpec, and a user specified StaggerLoc.

This example also illustrates a typical use of this Field creation method. By creating a Field from a Grid and an ArraySpec, the user allows the ESMF library to create an internal Array in the Field. Then the user can use ESMF_FieldGet() to retrieve the Fortran data array and necessary bounds information to assign initial values to it.

```fortran
! create a grid
```
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,20/), &
    regDecomp=(/2,2/), name="atmgrid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! setup arrayspec
    call ESMF_ArraySpecSet(arrayspec, 2, ESMF_TYPEKIND_R4, rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create a Field from the Grid and arrayspec
field1 = ESMF_FieldCreate(grid, arrayspec, &
    indexflag=ESMF_INDEX_DELOCAL, &
    staggerloc=ESMF_STAGGERLOC_CENTER, name="pressure", rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
    call ESMF_FieldGet(field1, localDe=0, farrayPtr=farray2dd, &
        totalLBound=ftlb, totalUBound=ftub, totalCount=ftc, rc =rc)
    do i = ftlb(1), ftub(1)
        do j = ftlb(2), ftub(2)
            farray2dd(i, j) = sin(i/ftc(1)*PI) * cos(j/ftc(2)*PI)
        enddo
    enddo
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

A user can also create an ArraySpec that has a different rank from the Grid. For example, the following code shows creation of of 3D Field from a 2D Grid using a 3D ArraySpec.

This example also demonstrates the technique to create a typical 3D data Field that has 2 gridded dimensions and 1 ungridded dimension.

First we create a 2D grid with an index space of 180x360 equivalent to 180x360 Grid cells (note that for a distributed memory computer, this means each grid cell will be on a separate PE!). In the FieldCreate call, we use gridToFieldMap to indicate the mapping between Grid dimension and Field dimension. For the ungridded dimension (typically the altitude), we use ungriddedLBound and ungriddedUBound to describe its bounds. Internally the ungridded dimension has a stride of 1, so the number of elements of the ungridded dimension is ungriddedUBound - ungriddedLBound + 1.

Note that gridToFieldMap in this specific example is (/1,2/) which is the default value so the user can neglect this argument for the FieldCreate call.

grid2d = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), &
    maxIndex=(/180,360/), regDecomp=(/2,2/), name="atmgrid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

    call ESMF_ArraySpecSet(arrayspec, 3, ESMF_TYPEKIND_R4, rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

field1 = ESMF_FieldCreate(grid2d, arrayspec, &
    indexflag=ESMF_INDEX_DELOCAL, &
    staggerloc=ESMF_STAGGERLOC_CENTER, &
    gridToFieldMap=(/1,2/), &
    ungriddedLBound=(/1/), ungriddedUBound=(/50/), &
    name="pressure", rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
25.3.6 Create a Field with a Grid and Array

A user can create an ESMF_Field from an ESMF_Grid and a ESMF_Array. The Grid was created in the previous example.

This example creates a 2D ESMF_Field from a 2D ESMF_Grid and a 2D ESMF_Array.

```fortran
! Get necessary information from the Grid
call ESMF_GridGet(grid, staggerloc=ESMF_STAGGERLOC_CENTER, 
distgrid=distgrid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Create a 2D ESMF_TYPEKIND_R4 arrayspec
call ESMF_ArraySpecSet(arrayspec, 2, ESMF_TYPEKIND_R4, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Create a ESMF_Array from the arrayspec and distgrid
array2d = ESMF_ArrayCreate(arrayspec=arrayspec, 
&
distgrid=distgrid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Create a ESMF_Field from the grid and array
field4 = ESMF_FieldCreate(grid, array2d, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

25.3.7 Create an empty Field and complete it with FieldEmptySet and FieldEmptyComplete

A user can create an ESMF_Field in three steps: first create an empty ESMF_Field; then set a ESMF_Grid on the empty ESMF_Field; and finally complete the ESMF_Field by calling ESMF_FieldEmptyComplete.

```fortran
! create an empty Field
field3 = ESMF_FieldEmptyCreate(name="precip", rc=rc)

! use FieldGet to retrieve the Field Status
call ESMF_FieldGet(field3, status=fstatus, rc=rc)
```

Once the Field is created, we can verify that the status of the Field is ESMF_FIELDSTATUS_EMPTY.

```fortran
! Test the status of the Field
if (fstatus /= ESMF_FIELDSTATUS_EMPTY) then
    call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
```

Next we set a Grid on the empty Field. We use the 2D grid created in a previous example simply to demonstrate the method. The Field data points will be on east edge of the Grid cells with the specified ESMF_STAGGERLOC_EDGE1.

```fortran
! Set a grid on the Field
```
call ESMF_FieldEmptySet(field3, grid2d, &
staggerloc=ESMF_STAGGERLOC_EDGE1, rc=rc)

! use FieldGet to retrieve the Field Status again
call ESMF_FieldGet(field3, status=fstatus, rc=rc)

! Test the status of the Field
if (fstatus /= ESMF_FIELDSTATUS_GRIDSET) then
    call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

The partially created Field is completed by specifying the typekind of its data storage. This method is overloaded with one of the following parameters, arrayspec, typekind, Fortran array, or Fortran array pointer. Additional optional arguments can be used to specify ungridded dimensions and halo regions similar to the other Field creation methods.

call ESMF_FieldEmptyComplete(field3, typekind=ESMF_TYPEKIND_R8, &
    ungriddedLBound=(/1/), ungriddedUBound=(/5/), rc=rc)

! use FieldGet to retrieve the Field Status again
call ESMF_FieldGet(field3, status=fstatus, rc=rc)

! Test the status of the Field
if (fstatus /= ESMF_FIELDSTATUS_COMPLETE) then
    call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

25.3.8 Create an empty Field and complete it with FieldEmptyComplete

A user can create an empty ESMF_Field. Then the user can finalize the empty ESMF_Field from a ESMF_Grid and a intrinsic Fortran data array. This interface is overloaded for typekind and rank of the Fortran data array.

In this example, both grid and Fortran array pointer are 2 dimensional and each dimension index maps in order, i.e. 1st dimension of grid maps to 1st dimension of Fortran array pointer, 2nd dimension of grid maps to 2nd dimension of Fortran array pointer, so on and so forth.

In order to create or complete a Field from a Grid and a Fortran array pointer, certain rules of the Fortran array bounds must be obeyed. We will discuss these rules as we progress in Field creation examples. We will make frequent reference to the terminologies for bounds and widths in ESMF. For a better discussion of these terminologies and concepts behind them, e.g. exclusive, computational, total bounds for the lower and upper corner of data region, etc., users can refer to the explanation of these concepts for Grid and Array in their respective sections in the Reference Manual, e.g. Section 27.2.6 on Array and Section 30.3.16 on Grid. The examples here are designed to help a user to get up to speed with creating Fields for typical use.

This example introduces a helper method, the ESMF_GridGetFieldBounds interface that facilitates the computation of Fortran data array bounds and shape to assist ESMF_FieldEmptyComplete finalizing a Field from a intrinsic Fortran data array and a Grid.
25.3.9 Create a 7D Field with a 5D Grid and 2D ungridded bounds from a Fortran data array

In this example, we will show how to create a 7D Field from a 5D ESMF_Grid and 2D ungridded bounds with arbitrary halo widths and gridToFieldMap.

We first create a 5D DistGrid and a 5D Grid based on the DistGrid; then ESMF_GridGetFieldBounds computes the shape of a 7D array in fsize. We can then create a 7D Field from the 5D Grid and the 7D Fortran data array with other assimilating parameters.

```fortran
! create a 5d distgrid
distgrid5d = ESMF_DistGridCreate(minIndex=(/1,1,1,1,1/), &
   maxIndex=(/10,4,10,4,6/), regDecomp=(/2,1,2,1,1/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Create a 5d Grid
grid5d = ESMF_GridCreate(distgrid=distgrid5d, name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! use FieldGet to retrieve total counts
call ESMF_GridGetFieldBounds(grid5d, localDe=0, &
   staggerloc=ESMF_STAGGERLOC_CENTER, totalCount=fsize, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! allocate the 7d Fortran array based on retrieved total counts
allocate(farray7d(fsize(1), fsize(2), fsize(3), fsize(4), fsize(5), &
   fsize(6), fsize(7)))

! create the Field
field7d = ESMF_FieldCreate(grid5d, farray7d, ESMF_INDEX_DELOCAL, &
   ungriddedLBound=(/1,2/), ungriddedUBound=(/4,5/), &
   totalLWidth=(/1,1,1,2,2/), totalUWidth=(/1,2,3,4,5/), &
   gridToFieldMap=(/3,2,5,4,1/), &
   rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```
A user can allocate the Fortran array in a different manner using the lower and upper bounds returned from FieldGet through the optional totalLBound and totalUBound arguments. In the following example, we create another 7D Field by retrieving the bounds and allocate the Fortran array with this approach. In this scheme, indexing the Fortran array is sometimes more convenient than using the shape directly.

```fortran
call ESMF_GridGetFieldBounds(grid5d, localDe=0, ungriddedLBound=(/1,2/), &
   ungriddedUBound=(/4,5/), &
   totalLWidth=(/1,1,1,2,2/), totalUWidth=(/1,2,3,4,5/), &
   gridToFieldMap=(/3,2,5,4,1/), &
   totalLBound=flbound, totalUBound=fubound, &
   rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
allocate(farray7d2(flbound(1):fubound(1), flbound(2):fubound(2), &
   flbound(3):fubound(3), flbound(4):fubound(4), &
   flbound(5):fubound(5), flbound(6):fubound(6), &
   flbound(7):fubound(7)) )
field7d2 = ESMF_FieldCreate(grid5d, farray7d2, ESMF_INDEX_DELOCAL, &
   ungriddedLBound=(/1,2/), ungriddedUBound=(/4,5/), &
   totalLWidth=(/1,1,1,2,2/), totalUWidth=(/1,2,3,4,5/), &
   gridToFieldMap=(/3,2,5,4,1/), &
   rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

25.3.10 Create a 2D Field with a 2D Grid and a Fortran data array

A user can create an ESMF_Field directly from an ESMF_Grid and an intrinsic Fortran data array. This interface is overloaded for typekind and rank of the Fortran data array.

In the following example, each dimension size of the Fortran array is equal to the exclusive bounds of its corresponding Grid dimension queried from the Grid through ESMF_GridGet() public interface.

Formally let fa_shape(i) be the shape of i-th dimension of user supplied Fortran array, then rule 1 states:

\[
(1) \text{fa\_shape}(i) = \text{exclusiveCount}(i) \\
\quad i = 1...\text{GridDimCount}
\]

fa_shape(i) defines the shape of i-th dimension of the Fortran array. ExclusiveCount are the number of data elements of i-th dimension in the exclusive region queried from ESMF_GridGet interface. Rule 1 assumes that the Grid and the Fortran intrinsic array have same number of dimensions; and optional arguments of FieldCreate from Fortran array are left unspecified using default setup. These assumptions are true for most typical use of FieldCreate from Fortran data array. This is the easiest way to create a Field from a Grid and Fortran intrinsic data array.

Fortran array dimension sizes (called shape in most Fortran language books) are equivalent to the bounds and counts used in this manual. The following equation holds:

\[
\text{fa\_shape}(i) = \text{shape}(i) = \text{counts}(i) = \text{upper\_bound}(i) - \text{lower\_bound}(i) + 1
\]
These typically mean the same concept unless specifically explained to mean something else. For example, ESMF uses DimCount very often to mean number of dimensions instead of its meaning implied in the above equation. We’ll clarify the meaning of a word when ambiguity could occur.

Rule 1 is most useful for a user working with Field creation from a Grid and a Fortran data array in most scenarios. It extends to higher dimension count, 3D, 4D, etc... Typically, as the code example demonstrates, a user first creates a Grid, then uses ESMF_GridGet() to retrieve the exclusive counts. Next the user calculates the shape of each Fortran array dimension according to rule 1. The Fortran data array is allocated and initialized based on the computed shape. A Field can either be created in one shot created empty and finished using ESMF_FieldEmptyComplete.

There are important details that can be skipped but are good to know for ESMF_FieldEmptyComplete and ESMF_FieldCreate from a Fortran data array. 1) these methods require each PET contains exactly one DE. This implies that a code using FieldCreate from a data array or FieldEmptyComplete must have the same number of DEs and PETs, formally \( n_{DE} = n_{PET} \). Violation of this condition will cause run time failures. 2) the bounds and counts retrieved from GridGet are DE specific or equivalently PET specific, which means that the Fortran array shape could be different from one PET to another.

```fortran
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,20/), &
   regDecomp=(/2,2/), name="atmgrid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_GridGet(grid, localDE=0, staggerloc=ESMF_STAGGERLOC_CENTER, &
   exclusiveCount=gec, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
allocate(farray(gec(1), gec(2)) )
field = ESMF_FieldCreate(grid, farray, ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

25.3.11 Create a 2D Field with a 2D Grid and a Fortran data pointer

The setup of this example is similar to the previous section except that the Field is created from a data pointer instead of a data array. We highlight the ability to deallocate the internal fortran data pointer queried from the Field. This gives a user more flexibility with memory management.

```fortran
allocate(farrayPtr(gec(1), gec(2)) )
field = ESMF_FieldCreate(grid, farrayPtr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(field, farrayPtr=farrayPtr2, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
deallocate(farrayPtr2)
```

25.3.12 Create a 3D Field with a 2D Grid and a 3D Fortran data array

This example demonstrates a typical use of ESMF_Field combining a 2D grid and a 3D Fortran native data array. One immediate problem follows: how does one define the bounds of the ungridded dimension? This is solved by the optional arguments ungriddedLBound and ungriddedUBound of the ESMF_FieldCreate interface. By definition, ungriddedLBound and ungriddedUBound are both 1 dimensional integer Fortran arrays.
Formally, let \( \text{fa\_shape}(j=1...\text{FieldDimCount-GridDimCount}) \) be the shape of the ungridded dimensions of a Field relative to the Grid used in Field creation. The Field dimension count is equal to the number of dimensions of the Fortran array, which equals the number of dimensions of the resultant Field. GridDimCount is the number of dimensions of the Grid.

\( \text{fa\_shape}(j) \) is computed as:

\[
\text{fa\_shape}(j) = \text{ungriddedUBound}(j) - \text{ungriddedLBound}(j) + 1
\]

\( \text{fa\_shape} \) is easy to compute when the gridded and ungridded dimensions do not mix. However, it’s conceivable that at higher dimension count, gridded and ungridded dimensions can interleave. To aid the computation of ungridded dimension shape we formally introduce the mapping concept.

Let \( \text{map}_{A,B}(i = 1...n_A) = i_B, \) and \( i_B \in [\phi, 1...n_B] \). \( n_A \) is the number of elements in set A, \( n_B \) is the number of elements in set B. \( \text{map}_{A,B}(i) \) defines a mapping from i-th element of set A to \( i_B \)-th element in set B. \( i_B = \phi \) indicates there does not exist a mapping from i-th element of set A to set B.

Suppose we have a mapping from dimension index of ungriddedLBound (or ungriddedUBound) to Fortran array dimension index, called ugb2fa. By definition, \( n_A \) equals to the dimension count of ungriddedLBound (or ungriddedUBound), \( n_B \) equals to the dimension count of the Fortran array. We can now formulate the computation of ungridded dimension shape as rule 2:

\[
(2) \quad \text{fa\_shape(ugb2fa}(j)) = \text{ungriddedUBound}(j) - \text{ungriddedLBound}(j) + 1
\]

\( j = 1..\text{FortranArrayDimCount} - \text{GridDimCount} \)

The mapping can be computed in linear time proportional to the Fortran array dimension count (or rank) using the following algorithm in pseudocode:

```plaintext
map_index = 1
do i = 1, farray_rank
    if i-th dimension of farray is ungridded
        ugb2fa(map_index) = i
        map_index = map_index + 1
    endif
endo
```

Here we use rank and dimension count interchangably. These 2 terminologies are typically equivalent. But there are subtle differences under certain conditions. Rank is the total number of dimensions of a tensor object. Dimension count allows a finer description of the heterogeneous dimensions in that object. For example, A Field of rank 5 can have 3 gridded dimensions and 2 ungridded dimensions. Rank is precisely the summation of dimension count of all types of dimensions.

For example, if a 5D array is used with a 3D Grid, there are 2 ungridded dimensions: ungriddedLBound=(/1,2/) and ungriddedUBound=(/5,7/). Suppose the distribution of dimensions look like (O, O, X, O, O), O means gridded, X means ungridded. Then the mapping from ungridded bounds to Fortran array is ugb2fa=(/2, 4/). The shape of 2nd and 4th dimension of Fortran array should equal (5, 8).

Back to our 3D Field created from a 2D Grid and 3D Fortran array example, suppose the 3rd Field dimension is ungridded, ungriddedLBound=(/3/), ungriddedUBound=(/9/). First we use rule 1 to compute shapes of the gridded
Fortran array dimension, then we use rule 2 to compute shapes of the ungridded Fortran array dimension. In this example, we used the exclusive bounds obtained in the previous example.

```fortran
fa_shape(1) = gec(1) ! rule 1
fa_shape(2) = gec(2)
fa_shape(3) = 7 ! rule 2 9-3+1
allocate(farray3d(fa_shape(1), fa_shape(2), fa_shape(3)))
field = ESMF_FieldCreate(grid, farray3d, ESMF_INDEX_DELOCAL, &
ungriddedLBound=(/3/), ungriddedUBound=(/9/), &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

25.3.13 Create a 3D Field with a 2D Grid and a 3D Fortran data array with gridToFieldMap argument

Building upon the previous example, we will create a 3D Field from a 2D grid and 3D array but with a slight twist. In this example, we introduce the gridToFieldMap argument that allows a user to map Grid dimension index to Field dimension index.

In this example, both dimensions of the Grid are distributed and the mapping from DistGrid to Grid is (/1,2/). We will introduce rule 3 assuming distgridToGridMap=(/1,2,3...gridDimCount/), and distgridDimCount equals to gridDimCount. This is a reasonable assumption in typical Field use.

We apply the mapping gridToFieldMap on rule 1 to create rule 3:

```fortran
(3) fa_shape(gridToFieldMap(i)) = exclusiveCount(i)
    i = 1,..GridDimCount.
```

Back to our example, suppose the 2nd Field dimension is ungridded, ungriddedLBound=(/3/), ungriddedUBound=(/9/). gridToFieldMap=(/3,1/), meaning the 1st Grid dimension maps to 3rd Field dimension, and 2nd Grid dimension maps to 1st Field dimension.

First we use rule 3 to compute shapes of the gridded Fortran array dimension, then we use rule 2 to compute shapes of the ungridded Fortran array dimension. In this example, we use the exclusive bounds obtained in the previous example.

```fortran
gridToFieldMap2d(1) = 3
gridToFieldMap2d(2) = 1
do i = 1, 2
   fa_shape(gridToFieldMap2d(i)) = gec(i)
end do
fa_shape(2) = 7
allocate(farray3d(fa_shape(1), fa_shape(2), fa_shape(3)))
field = ESMF_FieldCreate(grid, farray3d, ESMF_INDEX_DELOCAL, &
ungriddedLBound=(/3/), ungriddedUBound=(/9/), &
gridToFieldMap=gridToFieldMap2d, &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```
25.3.14 Create a 3D Field with a 2D Grid and a 3D Fortran data array with halos

This example is similar to example 25.3.13, in addition we will show a user can associate different halo width to a Fortran array to create a Field through the totalLWidth and totalUWidth optional arguments. A diagram of the dimension configuration from Grid, halos, and Fortran data array is shown here.

The `ESMF_FieldCreate()` interface supports creating a Field from a Grid and a Fortran array padded with halos on the distributed dimensions of the Fortran array. Using this technique one can avoid passing non-contiguous Fortran array slice to FieldCreate. It guarantees the same exclusive region, and by using halos, it also defines a bigger total region to contain the entire contiguous memory block of the Fortran array.

The elements of totalLWidth and totalUWidth are applied in the order distributed dimensions appear in the Fortran array. By definition, totalLWidth and totalUWidth are 1 dimensional arrays of non-negative integer values. The size of haloWidth arrays is equal to the number of distributed dimensions of the Fortran array, which is also equal to the number of distributed dimensions of the Grid used in the Field creation.

Because the order of totalWidth (representing both totalLWidth and totalUWidth) element is applied to the order distributed dimensions appear in the Fortran array dimensions, it’s quite simple to compute the shape of distributed dimensions of the Fortran array. They are done in a similar manner when applying ungriddedLBound and ungriddedUBound to ungridded dimensions of the Fortran array defined by rule 2.

Assume we have the mapping from the dimension index of totalWidth to the dimension index of Fortran array, called mhw2fa; and we also have the mapping from dimension index of Fortran array to dimension index of the Grid, called fa2g. The shape of distributed dimensions of a Fortran array can be computed by rule 4:

\[
(4) \text{fa\_shape}(mhw2fa(k)) = \text{exclusiveCount}(fa2g(mhw2fa(k))) + \\
\text{totalUWidth}(k) + \text{totalLWidth}(k) \\
k = 1...\text{size(totalWidth)}
\]

This rule may seem confusing but algorithmically the computation can be done by the following pseudocode:

```plaintext
fa_index = 1
for i = 1, farray_rank
  if i-th dimension of Fortran array is distributed
    fa_shape(i) = exclusiveCount(fa2g(i)) + \\
    totalUWidth(fa_index) + totalLWidth(fa_index)
    fa_index = fa_index + 1
  endif
endfor
```

The only complication then is to figure out the mapping from Fortran array dimension index to Grid dimension index. This process can be done by computing the reverse mapping from Field to Grid.

Typically, we don’t have to consider these complications if the following conditions are met: 1) All Grid dimensions are distributed. 2) DistGrid in the Grid has a dimension index mapping to the Grid in the form of natural order (/1,2,3,.../). This natural order mapping is the default mapping between various objects throughout ESMF. 3) Grid to Field mapping is in the form of natural order, i.e. default mapping. These seem like a lot of conditions but they are
ESMF_Field created from a 2D ESMF_Grid (Red) and a 3D Intrinsic Fortran data array (Green). The ungridded bounds and halo widths are applied to corresponding dimensions.
the default case in the interaction among DistGrid, Grid, and Field. When these conditions are met, which is typically true, the shape of distributed dimensions of Fortran array follows rule 5 in a simple form:

\[
(5) \text{fa\_shape}(k) = \text{exclusiveCount}(k) + \\
\text{totalUWidth}(k) + \text{totalLWidth}(k) \\
k = 1...\text{size}(\text{totalWidth})
\]

Let's examine an example on how to apply rule 5. Suppose we have a 5D array and a 3D Grid that has its first 3 dimensions mapped to the first 3 dimensions of the Fortran array. totalLWidth=(/1,2,3/), totalUWidth=(/7,9,10/), then by rule 5, the following pseudo code can be used to compute the shape of the first 3 dimensions of the Fortran array. The shape of the remaining two ungridded dimensions can be computed according to rule 2.

\[
\text{do } k = 1, 3 \\
\quad \text{fa\_shape}(k) = \text{exclusiveCount}(k) + \\
\quad \text{totalUWidth}(k) + \text{totalLWidth}(k) \\
\text{enddo}
\]

Suppose now gridToFieldMap=(/2,3,4/) instead which says the first dimension of Grid maps to the 2nd dimension of Field (or Fortran array) and so on and so forth, we can obtain a more general form of rule 5 by introducing first_distdim_index shift when Grid to Field map (gridToFieldMap) is in the form of (/a,a+1,a+2.../).

\[
(6) \text{fa\_shape}(k+\text{first\_distdim\_index}-1) = \text{exclusiveCount}(k) + \\
\text{totalUWidth}(k) + \text{totalLWidth}(k) \\
k = 1...\text{size}(\text{totalWidth})
\]

It's obvious that first_distdim_index=a. If the first dimension of the Fortran array is distributed, then rule 6 degenerates into rule 5, which is the typical case.

Back to our example creating a 3D Field from a 2D Grid and a 3D intrinsic Fortran array, we will use the Grid created from previous example that satisfies condition 1 and 2. We'll also use a simple gridToFieldMap (1,2) which is the default mapping that satisfies condition 3. First we use rule 5 to compute the shape of distributed dimensions then we use rule 2 to compute the shape of the ungridded dimensions.

\[
\text{gridToFieldMap2d}(1) = 1 \\
\text{gridToFieldMap2d}(2) = 2 \\
\text{totalLWidth2d}(1) = 3 \\
\text{totalLWidth2d}(2) = 4 \\
\text{totalUWidth2d}(1) = 3 \\
\text{totalUWidth2d}(2) = 5 \\
\text{do } k = 1, 2 \\
\quad \text{fa\_shape}(k) = \text{gec}(k) + \text{totalLWidth2d}(k) + \text{totalUWidth2d}(k) \\
\text{end do} \\
\text{fa\_shape}(3) = 7 \quad ! 9-3+1 \\
\text{allocate(farray3d(fa\_shape(1), fa\_shape(2), fa\_shape(3)))}
\]
field = ESMF_FieldCreate(grid, farray3d, ESMF_INDEX_DELOCAL, &
ungriddedLBound=(/3/), ungriddedUBound=(/9/), &
totalLWidth=totalLWidth2d, totalUWidth=totalUWidth2d, &
gridToFieldMap=gridToFieldMap2d, &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.15  Create a Field from a LocStream, typekind, and rank

In this example, an ESMF_Field is created from an ESMF_LocStream and typekind/rank. The location stream object is uniformly distributed in a 1 dimensional space on 4 DEs. The rank is 1 dimensional. Please refer to LocStream examples section for more information on LocStream creation.

locs = ESMF_LocStreamCreate(minIndex=1, maxIndex=16, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

field = ESMF_FieldCreate(locs, typekind=ESMF_TYPEKIND_I4, &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.16  Create a Field from a LocStream and arrayspec

In this example, an ESMF_Field is created from an ESMF_LocStream and an ESMF_Arrayspec. The location stream object is uniformly distributed in a 1 dimensional space on 4 DEs. The arrayspec is 1 dimensional. Please refer to LocStream examples section for more information on LocStream creation.

locs = ESMF_LocStreamCreate(minIndex=1, maxIndex=16, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_ArraySpecSet(arrayspec, 1, ESMF_TYPEKIND_I4, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

field = ESMF_FieldCreate(locs, arrayspec, &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.17  Create a Field from a Mesh, typekind, and rank

In this example, an ESMF_Field is created from an ESMF_Mesh and typekind/rank. The mesh object is on a Euclidean surface that is partitioned to a 2x2 rectangular space with 4 elements and 9 nodes. The nodal space is represented by a distgrid with 9 indices. Field is created on locally owned nodes on each PET. Therefore, the created Field has 9 data points globally. The mesh object can be represented by the picture below. For more information on Mesh creation, please see Section [2.3.1]
25.3.18 Create a Field from a Mesh and arrayspec

In this example, an `ESMF_Field` is created from an `ESMF_Mesh` and an `ESMF_Arrayspec`. The mesh object is on a Euclidean surface that is partitioned to a 2x2 rectangular space with 4 elements and 9 nodes. The nodal space is
represented by a distgrid with 9 indices. Field is created on locally owned nodes on each PET. Therefore, the created
Field has 9 data points globally. The mesh object can be represented by the picture below. For more information on
Mesh creation, please see Section [32.3.1]

! Create Mesh structure in 1 step
mesh=ESMF_MeshCreate(parametricDim=2,spatialDim=2, &
  nodeIds=nodeIds, nodeCoords=nodeCoords, &
  nodeOwners=runodeOwners, elementIds=elemIds,&
  elementTypes=elemTypes, elementConn=elemConn, &
  rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_MeshGet(mesh, nodalDistgrid=distgrid, rc=rc)
array = ESMF_ArrayCreate(distgrid=distgrid, arrayspec=arrayspec, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
! Field is created on the 1 dimensional nodal distgrid. On
! each PET, Field is created on the locally owned nodes.
field = ESMF_FieldCreate(mesh, arrayspec, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.19 Create a Field from a Mesh and an Array

In this example, an ESMF_Field is created from an ESMF_Mesh and an ESMF_Array. The mesh object is created
in the previous example and the array object is retrieved from the field created in the previous example too.

call ESMF_MeshGet(mesh, nodalDistgrid=distgrid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
array = ESMF_ArrayCreate(distgrid=distgrid, arrayspec=arrayspec, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
! query the array from the previous example
call ESMF_FieldGet(field, array=array, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
! create a Field from a mesh and an array
field1 = ESMF_FieldCreate(mesh, array, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.20 Create a Field from a Mesh and an ArraySpec with optional features

In this example, an ESMF_Field is created from an ESMF_Mesh and an ESMF_ArraySpec. The mesh object is
created in the previous example. The Field is also created with optional arguments such as ungridded dimensions and
dimension mapping.

In this example, the mesh is mapped to the 2nd dimension of the ESMF_Field, with its first dimension being the
ungridded dimension with bounds 1,3.

call ESMF_ArraySpecSet(arrayspec, 2, ESMF_TYPEKIND_I4, rc=rc)
field = ESMF_FieldCreate(mesh, arrayspec=arrayspec, gridToFieldMap=(/2/), &
  ungriddedLBound=(/1/), ungriddedUBound=(/3/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
25.3.21 Create a Field with replicated dimensions

In this example an ESMF_Field with replicated dimension is created from an ESMF_Grid and an ESMF_Arrayspec. A user can also use other ESMF_FieldCreate() methods to create replicated dimension Field, this example illustrates the key concepts and use of a replicated dimension Field.

Normally gridToFieldMap argument in ESMF_FieldCreate() should not contain 0 value entries. However, for Field with replicated dimension, a 0 entry in gridToFieldMap indicates the corresponding Grid dimension is replicated in the Field. In such a Field, the rank of the Field is no longer necessarily greater than its Grid rank. An example will make this clear. We will start by creating Distgrid and Grid.

```fortran
! create 4D distgrid
distgrid = ESMF_DistGridCreate(minIndex=(/1,1,1,1/), &
    maxIndex=(/6,4,6,4/), regDecomp=(/2,1,2,1/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create 4D grid on top of the 4D distgrid
grid = ESMF_GridCreate(distgrid=distgrid, name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create 3D arrayspec
call ESMF_ArraySpecSet(arrayspec, 3, ESMF_TYPEKIND_R8, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

In this example, a user creates a 3D Field with replicated dimension replicated along the 2nd and 4th dimension of its underlying 4D Grid. In addition, the 2nd dimension of the Field is ungridded (why?). The 1st and 3rd dimensions of the Field have halos.

```fortran
! create field, 2nd and 4th dimensions of the Grid are replicated
field = ESMF_FieldCreate(grid, arrayspec, indexFlag=ESMF_INDEX_DELOCAL, &
    gridToFieldMap=(/1,0,2,0/), &
    ungriddedLBound=(/1/), ungriddedUBound=(/4/), &
    totalLWidth=(/1,1/), totalUWidth=(/4,5/), &
    staggerloc=ESMF_STAGGERLOC_CORNER, &
    rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

```fortran
! get basic information from the field
call ESMF_FieldGet(field, grid=grid1, array=array, typekind=typekind, &
    dimCount=dimCount, staggerloc=lstaggerloc, &
    gridToFieldMap=gridToFieldMap, ungriddedLBound=ungriddedLBound, &
    ungriddedUBound=ungriddedUBound, totalLWidth=totalLWidth, &
    totalUWidth=totalUWidth, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

```fortran
! get bounds information from the field
call ESMF_FieldGet(field, localDe=0, farrayPtr=farray, &
    exclusiveLBound=felb, exclusiveUBound=feub, exclusiveCount=fec, &
    computationalLBound=fclb, computationalUBound=fcutb, &
    computationalCount=fcc, totalLBound=ftlb, totalUBound=ftub, &
    totalCount=ftc, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```
Next we verify that the field and array bounds agree with each other

```fortran
    call ESMF_ArrayGet(array, rank=arank, dimCount=adimCount, rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

    gridrank_repdim = 0
    do i = 1, size(gridToFieldMap)
      if(gridToFieldMap(i) == 0) gridrank_repdim = gridrank_repdim + 1
    enddo
```

Number of undistributed dimension of the array \( X \) is computed from total rank of the array \( A \), the dimension count of its underlying distgrid \( B \) and number of replicated dimension in the distgrid \( C \). We have the following formula: \( X = A - (B - C) \)

```fortran
    allocate(audlb(arank-adimCount+gridrank_repdim), &
            audub(arank-adimCount+gridrank_repdim))
    call ESMF_ArrayGet(array, exclusiveLBound=aelb, exclusiveUBound=aeub, &
                       computationalLBound=aclb, computationalUBound=acub, &
                       totalLBound=atlb, totalUBound=atub, &
                       undistLBound=audlb, undistUBound=audub, &
                       rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

    ! verify the ungridded bounds from field match
    ! undistributed bounds from its underlying array
    do i = 1, arank-adimCount
      if(lungriddedLBound(i) .ne. audlb(i) ) &
         rc = ESMF_FAILURE
    enddo
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

    do i = 1, arank-adimCount
      if(lungriddedUBound(i) .ne. audub(i) ) &
         rc = ESMF_FAILURE
    enddo
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

We then verify the data in the replicated dimension Field can be updated and accessed.

```fortran
    do ik = ftlb(3), ftub(3)
      do ij = ftlb(2), ftub(2)
        do ii = ftlb(1), ftub(1)
          farray(ii,ij,ik) = ii+ij*2+ik
        enddo
      enddo
    enddo
    ! access and verify
    call ESMF_FieldGet(field, localDe=0, farrayPtr=farray1, &
                        rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
    do ik = ftlb(3), ftub(3)
```
do  ij = ftlb(2), ftub(2)
  do ii = ftlb(1), ftub(1)
    n = ii+ij*2+ik
    if(farray1(ii,ij,ik) .ne. n ) rc = ESMF_FAILURE
  enddo
enddo
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! release resources
call ESMF_FieldDestroy(field)
call ESMF_GridDestroy(grid)
call ESMF_DistGridDestroy(distgrid)

25.3.22  Create a Field on an arbitrarily distributed Grid

With the introduction of Field on arbitrarily distributed Grid, Field has two kinds of dimension count: one associated geometrical (or physical) dimensionality, the other one associated with its memory index space representation. Field and Grid dimCount reflect the physical index space of the objects. A new type of dimCount rank should be added to both of these entities. rank gives the number of dimensions of the memory index space of the objects. This would be the dimension of the pointer pulled out of Field and the size of the bounds vector, for example.

For non-arbitrary Grids rank=dimCount, but for grids and fields with arbitrary dimensions rank = dimCount - (number of Arb dims) + 1 (Internally Field can use the Arb info from the grid to create the mapping from the Field Array to the DistGrid)

When creating a Field size(GridToFieldMap)=dimCount for both Arb and Non-arb grids This array specifies the mapping of Field to Grid identically for both Arb and Nonarb grids If a zero occurs in an entry corresponding to any arbitrary dimension, then a zero must occur in every entry corresponding to an arbitrary dimension (i.e. all arbitrary dimensions must either be all replicated or all not replicated, they can’t be broken apart).

In this example an ESMF_Field is created from an arbitrarily distributed ESMF_Grid and an ESMF_Arrayspec. A user can also use other ESMF_FieldCreate() methods to create such a Field, this example illustrates the key concepts and use of Field on arbitrary distributed Grid.

The Grid is 3 dimensional in physics index space but the first two dimension are collapsed into a single memory index space. Thus the result Field is 3D in physics index space and 2D in memory index space. This is made obvious with the 2D arrayspec used to create this Field.

! create a 3D grid with the first 2 dimensions collapsed
! and arbitrarily distributed
grid3d = ESMF_GridCreateNoPeriDim(coordTypeKind=ESMF_TYPEKIND_R8, &
  minIndex=/1,1,1/), maxIndex=/xdim, ydim,zdim/), &
  arbIndexList=localArbIndex,arbIndexCount=localArbIndexCount, &
  name="arb3dgrid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create a 2D arrayspec
call ESMF_ArraySpecSet(arrayspec2D, rank=2, typekind=ESMF_TYPEKIND_R4, &
  rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create a 2D Field using the Grid and the arrayspec
field = ESMF_FieldCreate(grid3d, arrayspec2D, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(field, rank=rank, dimCount=dimCount, &
   rc=rc)
if (myPet .eq. 0) print *, 'Field rank, dimCount', &
   rank, dimCount
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! verify that the dimension counts are correct
if (rank .ne. 2) correct = .false.
if (dimCount .ne. 3) correct = .false.

25.3.23 Create a Field on an arbitrarily distributed Grid with replicated dimensions & ungridded bounds

The next example is slightly more complicated in that the Field also contains ungridded dimension and its gridded dimension is replicated on the arbitrarily distributed dimension of the Grid.

The same 3D Grid and 2D arrayspec in the previous example are used but a gridToFieldMap argument is supplied to the ESMF_FieldCreate() call. The first 2 entries of the map are 0, the last (3rd) entry is 1. The 3rd dimension of the Grid is mapped to the first dimension of the Field, this dimension is then replicated on the arbitrarily distributed dimensions of the Grid. In addition, the Field also has one ungridded dimension. Thus the final dimension count of the Field is 2 in both physics and memory index space.

field = ESMF_FieldCreate(grid3d, arrayspec2D,gridToFielMap=(/0,0,1/), &
   ungriddedLBound=(/1/), ungriddedUBound=(/10/),rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(field, rank=rank, dimCount=dimCount, &
   rc=rc)
if (myPet .eq. 0) print *, 'Field rank, dimCount', &
   rank, dimCount
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

if (rank .ne. 2) correct = .false.
if (dimCount .ne. 3) correct = .false.

25.3.24 Field regridding

This section describes the Field regrid methods. For an in depth description of ESMF regridding and the options available please see Section 23.2.

The basic flow of using ESMF Field regridding is as follows. First a source and destination grid object are created, both can be either a Grid or Mesh. Coordinates are set during Mesh creation, but for the Grid they must be set separately using the ESMF_GridAddCoord() and ESMF_GridGetCoord() methods. Next Fields are built on the source and destination grid objects. These Fields are then passed into ESMF_FieldRegridStore(). The user can either get a sparse matrix from this call and/or a routeHandle. If the user gets the sparse matrix then they are responsible for deallocating it, but other than that can use it as they wish. The routeHandle can be used in the ESMF_FieldRegrid() call to perform the actual interpolation of data from the source to the destination field. This interpolation can be repeated for the same set of Fields as long as the coordinates at the staggerloc involved in the regridding in the associated grid object don’t change. The same routeHandle can also be used between any pair of Fields which is weakly congruent to the pair used to create the routeHandle. Congruent Fields possess matching
DistGrids and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. You can apply the routehandle between any set of Fields weakly congruent to the original Fields used to create the routehandle without incurring an error. However, if you want the routehandle to be the same interpolation between the grid objects upon which the Fields are built as was calculated with the original `ESMF_FieldRegridStore()` call, then there are additional constraints on the grid objects. To be the same interpolation, the grid objects upon which the Fields are build must contain the same coordinates at the stagger locations involved in the regidding as the original source and destination Fields used in the `ESMF_FieldRegridStore()` call. The routehandle represents the interpolation between the grid objects as they were during the `ESMF_FieldRegridStore()` call. So if the coordinates at the stagger location in the grid objects change, a new call to `ESMF_FieldRegridStore()` is necessary to compute the interpolation between that new set of coordinates. When finished with the routeHandle `ESMF_FieldRegridRelease()` should be used to free the associated memory.

The following example demonstrates doing a regrid operation between two Fields.

```fortran
! (Create source Grid or Mesh.)
! (Create srcField on this Grid or Mesh)

! (Create destination Grid or Mesh.)
! (Create dstField on this Grid or Mesh)

! Create the routeHandle which encodes the communication and
! information necessary for the regrid sparse matrix multiply.
call ESMF_FieldRegridStore(srcField=srcField, dstField=dstField, &
   routeHandle=routeHandle, &
   regridmethod=ESMF_REGRIDMETHOD_BILINEAR, rc=localrc)

! Can loop here regridding from srcField to dstField as long as
! source and destination Grid or Mesh don’t change.
! do i=1,....
!
! (Put data into srcField)
!
! Use the routeHandle to regrid data from srcField to dstField.
! As described above, the same routeHandle can be used to
! regrid any source and destination Fields which are weakly
! congruent to the original srcField and dstField.
call ESMF_FieldRegrid(srcField, dstField, routeHandle, rc=localrc)

! (Use data in dstField)
!
enddo
!

! Free the buffers and data associated with the routeHandle.
call ESMF_FieldRegridRelease(routeHandle, rc=localrc)
```
25.3.25  Field regrid with masking

As before, to create the sparse matrix regrid operator we call the ESMF_FieldRegridStore() routine. However, in this case we apply masking to the regrid operation. The mask value for each index location in the Grids may be set using the ESMF_GridAddItem() call (see Section 30.3.14 and Section 30.3.15). Mask values may be set independently for the source and destination Grids. If no mask values have been set in a Grid, then it is assumed no masking should be used for that Grid. The srcMaskValues parameter allows the user to set the list of values which indicate that a source location should be masked out. The dstMaskValues parameter allows the user to set the list of values which indicate that a destination location should be masked out. The absence of one of these parameters indicates that no masking should be used for that Field (e.g. no srcMaskValue parameter indicates that source masking shouldn’t occur). The unmappedAction flag may be used with or without masking and indicates what should occur if destination points can not be mapped to a source cell. Here the ESMF_UNMAPPEDACTION_IGNORE value indicates that unmapped destination points are to be ignored and no sparse matrix entries should be generated for them.

\[
\text{call ESMF\_FieldRegridStore(srcField=srcField, srcMaskValues=}/1/\text{, &}
\text{dstField=dstField, dstMaskValues=}/1/\text{, &}
\text{unmappedaction=ESMF\_UNMAPPEDACTION\_IGNORE, &}
\text{routeHandle=routeHandle, &}
\text{regridmethod=ESMF\_REGRIDMETHOD\_BILINEAR, &}
\text{rc=localrc)}
\]

The ESMF_FieldRegrid and ESMF_FieldRegridRelease calls may then be applied as in the previous example.

25.3.26  Field regrid example: Mesh to Mesh

This example demonstrates the regridding process between Fields created on Meshes. First the Meshes are created. This example omits the setup of the arrays describing the Mesh, but please see Section 32.3.1 for examples of this. After creation Fields are constructed on the Meshes, and then ESMF_FieldRegridStore() is called to construct a RouteHandle implementing the regrid operation. Finally, ESMF_FieldRegrid() is called with the Fields and the RouteHandle to do the interpolation between the source Field and destination Field. Note the coordinates of the source and destination Mesh should be in degrees.

25.3.27 Gather Field data onto root PET

User can use ESMF_FieldGather interface to gather Field data from multiple PETS onto a single root PET. This interface is overloaded by type, kind, and rank.

Note that the implementation of Scatter and Gather is not sequence index based. If the Field is built on arbitrarily distributed Grid, Mesh, LocStream or XGrid, Gather will not gather data to rootPet from source data points corresponding to the sequence index on the rootPet. Instead Gather will gather a contiguous memory range from source PET to rootPet. The size of the memory range is equal to the number of data elements on the source PET. Vice versa for the Scatter operation. In this case, the user should use ESMF_FieldRedist to achieve the same data operation result. For examples how to use ESMF_FieldRedist to perform Gather and Scatter, please refer to 25.3.31 and 25.3.30.

In this example, we first create a 2D Field, then use ESMF_FieldGather to collect all the data in this Field into a data pointer on PET 0.

```fortran
! Get current VM and pet number
call ESMF_VMGetCurrent(vm, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_VMGet(vm, localPet=lpe, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Create a 2D Grid and use this grid to create a Field
! farray is the Fortran data array that contains data on each PET.
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,20/), &
regDecomp=(/2,2/), &
name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

field = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_I4, rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

!---------Initialize pet specific field data-----------

! 1  5  10
! 0  1
! 2  3
! 20
fptr = lpe

! allocate the Fortran data array on PET 0 to store gathered data
if(lpe .eq. 0) then
allocate (farrayDst(10,20))
else
allocate (farrayDst(0,0))
end if

call ESMF_FieldGather(field, farrayDst, rootPet=0, rc=rc)
```

297
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! check that the values gathered on rootPet are correct
if(lpe .eq. 0) then
  do i = 1, 5
    do j = 1, 10
      if(farrayDst(i, j) .ne. 0) localrc=ESMF_FAILURE
    enddo
  enddo
  if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
  do i = 6, 10
    do j = 1, 10
      if(farrayDst(i, j) .ne. 1) localrc=ESMF_FAILURE
    enddo
  enddo
  if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
  do i = 1, 5
    do j = 11, 20
      if(farrayDst(i, j) .ne. 2) localrc=ESMF_FAILURE
    enddo
  enddo
  if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
  do i = 6, 10
    do j = 11, 20
      if(farrayDst(i, j) .ne. 3) localrc=ESMF_FAILURE
    enddo
  enddo
  if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

! destroy all objects created in this example to prevent memory leak
! call ESMF_FieldDestroy(field, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_GridDestroy(grid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
if(lpe .eq. 0) deallocate(farrayDst)

25.3.28 Scatter Field data from root PET onto its set of joint PETs

User can use ESMF_FieldScatter interface to scatter Field data from root PET onto its set of joint PETs. This interface is overloaded by type, kind, and rank.

In this example, we first create a 2D Field, then use ESMF_FieldScatter to scatter the data from a data array located on PET 0 onto this Field.

! Create a 2D Grid and use this grid to create a Field
! farray is the Fortran data array that contains data on each PET.
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,20/), &
       regDecomp=(/2,2/), &
       name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
field = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_I4, rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! initialize values to be scattered
! 1 5 10
! 1 +--------+---------+
! | | |
! | 0 | 1 |
! | | |
! 10 +--------+---------+
! | | |
! | 2 | 3 |
! | | |
! 20 +--------+---------+
if(lpe .eq. 0) then
allocate(farraySrc(10,20))
  farraySrc(1:5,1:10) = 0
  farraySrc(6:10,1:10) = 1
  farraySrc(1:5,11:20) = 2
  farraySrc(6:10,11:20) = 3
else
  allocate (farraySrc(0,0))
endif

! scatter the data onto individual PETs of the Field
call ESMF_FieldScatter(field, farraySrc, rootPet=0, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(field, localDe=0, farrayPtr=fptr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! verify that the scattered data is properly distributed
do i = lbound(fptr, 1), ubound(fptr, 1)
do j = lbound(fptr, 2), ubound(fptr, 2)
  if(fptr(i, j) .ne. lpe) localrc = ESMF_FAILURE
enddo
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
enddo

! destroy all objects created in this example to prevent memory leak
call ESMF_FieldDestroy(field, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_GridDestroy(grid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
if(lpe .eq. 0) deallocate(farraySrc)

25.3.29 Redistribute data from source Field to destination Field

User can use ESMF_FieldRedist interface to redistribute data from source Field to destination Field. This interface is overloaded by type and kind; In the version of ESMF_FieldRedist without factor argument, a default value of 1 is used.

In this example, we first create two 1D Fields, a source Field and a destination Field. Then we use ESMF_FieldRedist to redistribute data from source Field to destination Field.

299
! Get current VM and pet number
call ESMF_VMGetCurrent(vm, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_VMGet(vm, localPet=localPet, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create grid
distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/16/), &
    regDecomp=(/4/), &
    rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
grid = ESMF_GridCreate(distgrid=distgrid, &
    name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create srcField
+--------+--------+--------+--------+
| 0 1 2 3 |
| 4 8 12 16 |
! value
! bounds
! create dstField
+--------+--------+--------+--------+
| 0 0 0 0 |
| 1 4 8 12 16 |
! value
! bounds

srcField = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_I4, &
    indexflag=ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(srcField, farrayPtr=srcfptr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
srcfptr(:) = localPet

dstField = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_I4, &
    indexflag=ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldGet(dstField, farrayPtr=dstfptr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

dstfptr(:) = 0

! perform redist
! 1. setup routehandle from source Field to destination Field
call ESMF_FieldRedistStore(srcField, dstField, routehandle, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! 2. use precomputed routehandle to redistribute data
call ESMF_FieldRedist(srcField, dstField, routehandle, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! verify redist
call ESMF_FieldGet(dstField, localDe=0, farrayPtr=fptr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! Verify that the redistributed data in dstField is correct.
! Before the redist op, the dst Field contains all 0.
! The redist op reset the values to the PE value, verify this is the case.
do i = lbound(fptr, 1), ubound(fptr, 1)
  if(fptr(i) .ne. localPet) localrc = ESMF_FAILURE
enddo
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

Field redistribution can also be performed between weakly congruent Fields. In this case, source and destination Fields can have ungridded dimensions with size different from the Field pair used to compute the routehandle.

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_I4, rank=2, rc=rc)

Create two fields with ungridded dimensions using the Grid created previously. The new Field pair has matching number of elements. The ungridded dimension is mapped to the first dimension of either Field.

srcFieldA = ESMF_FieldCreate(grid, arrayspec, gridToFieldMap=(/2/), &
  ungriddedLBound=(/1/), ungriddedUBound=(/10/), rc=rc)

dstFieldA = ESMF_FieldCreate(grid, arrayspec, gridToFieldMap=(/2/), &
  ungriddedLBound=(/1/), ungriddedUBound=(/10/), rc=rc)

Using the previously computed routehandle, weakly congruent Fields can be redistributed.

call ESMF_FieldRedist(srcfieldA, dstFieldA, routehandle, rc=rc)

call ESMF_FieldRedistRelease(routehandle, rc=rc)

25.3.30 FieldRedist as a form of scatter involving arbitrary distribution

User can use ESMF_FieldRedist interface to redistribute data from source Field to destination Field, where the destination Field is built on an arbitrarily distributed structure, e.g. ESMF_Mesh. The underlying mechanism is explained in section 27.2.18.

In this example, we will create 2 one dimensional Fields, the src Field has a regular decomposition and holds all its data on a single PET, in this case PET 0. The destination Field is built on a Mesh which is itself built on an arbitrarily distributed distgrid. Then we use ESMF_FieldRedist to redistribute data from source Field to destination Field, similar to a traditional scatter operation.

The src Field only has data on PET 0 where it is sequentially initialized, i.e. 1,2,3...This data will be redistributed (or scattered) from PET 0 to the destination Field arbitrarily distributed on all the PETs.

! a one dimensional grid whose elements are all located on PET 0
distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/9/), &
   regDecomp=(/1/), &
   rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
grid = ESMF_GridCreate(distgrid=distgrid, &
   indexflag=ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
srcField = ESMF_FieldCreate(grid, typekind=ESMF_TYPEKIND_I4, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!

! initialize the source data
if (localPet == 0) then
   call ESMF_FieldGet(srcField, farrayPtr=srcfptr, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
   do i = 1, 9
      srcfptr(i) = i
   enddo
endif
!
Create Mesh structure
mesh=ESMF_MeshCreate(parametricDim=2,spatialDim=2, &
   nodeIds=nodeIds, nodeCoords=nodeCoords, &
   nodeOwners=nodeOwners, elementIds=elemIds, &
   elementTypes=elemTypes, elementConn=elemConn, &
   rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

Create the destination Field on the Mesh that is arbitrarily distributed on all the PETs.

   dstField = ESMF_FieldCreate(mesh, typekind=ESMF_TYPEKIND_I4, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

Perform the redistribution from source Field to destination Field.

   call ESMF_FieldRedistStore(srcField, dstField, &
      routehandle=routehandle, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_FieldRedist(srcField, dstField, routehandle=routehandle, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

We can now verify that the sequentially initialized source data is scattered on to the destination Field. The data has been scattered onto the destination Field with the following distribution.
Because the redistribution is index based, the elements also corresponds to the index space of Mesh in the destination Field.

```fortran
    call ESMF_FieldGet(dstField, farrayPtr=dstfptr, rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

The scatter operation is successful. Since the routehandle computed with `ESMF_FieldRedistStore` can be reused, user can use the same routehandle to scatter multiple source Fields from a single PET to multiple destination Fields distributed on all PETs. The gathering operation is just the opposite of the demonstrated scattering operation, where a user would redist from a source Field distributed on multiple PETs to a destination Field that only has data storage on a single PET.

Now it’s time to release all the resources.

```fortran
    call ESMF_FieldRedistRelease(routehandle=routehandle, rc=rc)
```

### 25.3.31 FieldRedist as a form of gather involving arbitrary distribution

Similarly, one can use the same approach to gather the data from an arbitrary distribution to a non-arbitrary distribution. This concept is demonstrated by using the previous Fields but the data operation is reversed. This time data is gathered from the Field built on the mesh to the Field that has only data allocation on rootPet.

First a FieldRedist routehandle is created from the Field built on Mesh to the Field that has only data allocation on rootPet.

```fortran
    call ESMF_FieldRedistStore(dstField, srcField, routehandle=routehandle, &
                               rc=rc)
```

Perform FieldRedist, this will gather the data points from the Field built on mesh to the data pointer on the rootPet (default to 0) stored in the srcField.

```fortran
    call ESMF_FieldRedist(dstField, srcField, routehandle=routehandle, rc=rc)
```

Release the routehandle used for the gather operation.

```fortran
    call ESMF_FieldRedistRelease(routehandle=routehandle, rc=rc)
```
25.3.32 Sparse matrix multiplication from source Field to destination Field

A user can use ESMF_FieldSMM() interface to perform sparse matrix multiplication from source Field to destination Field. This interface is overloaded by type and kind;

In this example, we first create two 1D Fields, a source Field and a destination Field. Then we use ESMF_FieldSMM to perform sparse matrix multiplication from source Field to destination Field.

The source and destination Field data are arranged such that each of the 4 PETs has 4 data elements. Moreover, the source Field has all its data elements initialized to a linear function based on local PET number. Then collectively on each PET, a SMM according to the following formula is performed:

$$dstField(i) = i \times srcField(i), i = 1...4$$

Because source Field data are initialized to a linear function based on local PET number, the formula predicts that the result destination Field data on each PET is 1,2,3,4. This is verified in the example.

Section 27.2.17 provides a detailed discussion of the sparse matrix multiplication operation implemented in ESMF.

```fortran
! Get current VM and pet number
   call ESMF_VMGetCurrent(vm, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

   call ESMF_VMGet(vm, localPet=lpe, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create distgrid and grid
   distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/16/), &
                                  regDecomp=(/4/), &
                                  rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
   grid = ESMF_GridCreate(distgrid=distgrid, &
                           name="grid", rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

   call ESMF_GridGetFieldBounds(grid, localDe=0, totalCount=fa_shape, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create src_farray, srcArray, and srcField
   ! +--------+--------+--------+--------+
   ! 1 2 3 4 ! value
   ! 1 4 8 12 16 ! bounds
   allocate(src_farray(fa_shape(1)))
   src_farray = lpe+1
   srcArray = ESMF_ArrayCreate(distgrid, src_farray, &
                                indexflag=ESMF_INDEX_DELOCAL, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

   srcField = ESMF_FieldCreate(grid, srcArray, rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! create dst_farray, dstArray, and dstField
   ! +--------+--------+--------+--------+
   ! 0 0 0 0 ! value
```
allocate(dst_farray(fa_shape(1)))
dst_farray = 0
dstArray = ESMF_ArrayCreate(distgrid, dst_farray, 
indexflag=ESMF_INDEX_DELOCAL, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
dstField = ESMF_FieldCreate(grid, dstArray, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!
perform sparse matrix multiplication
!
1. setup routehandle from source Field to destination Field
! initialize factorList and factorIndexList
allocate(factorList(4))
allocate(factorIndexList(2,4))
factorList = (/1,2,3,4/)
factorIndexList(1,:) = (/lpe*4+1,lpe*4+2,lpe*4+3,lpe*4+4/)
factorIndexList(2,:) = (/lpe*4+1,lpe*4+2,lpe*4+3,lpe*4+4/)
call ESMF_FieldSMMStore(srcField, dstField, routehandle, 
factorList, factorIndexList, rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!
2. use precomputed routehandle to perform SMM
call ESMF_FieldSMM(srcField, dstField, routehandle, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!
verify sparse matrix multiplication
call ESMF_FieldGet(dstField, localDe=0, farrayPtr=fptr, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!
Verify that the result data in dstField is correct.
! Before the SMM op, the dst Field contains all 0.
! The SMM op reset the values to the index value, verify this is the case.
! +--------+--------+--------+--------+
! 1 2 3 4 2 4 6 8 3 6 9 12 4 8 12 16 ! value
! 1 4 8 12 16 ! bounds
do i = lbound(fptr, 1), ubound(fptr, 1)
  if(fptr(i) /= i*(lpe+1)) rc = ESMF_FAILURE
enddo

Field sparse matrix matmul can also be performed between weakly congruent Fields. In this case, source and destination Fields can have ungridded dimensions with size different from the Field pair used to compute the routehandle.

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_I4, rank=2, rc=rc)

Create two fields with ungridded dimensions using the Grid created previously. The new Field pair has matching number of elements. The ungridded dimension is mapped to the first dimension of either Field.

srcFieldA = ESMF_FieldCreate(grid, arrayspec, gridToFieldMap=(/2/), 
ungriddedLBound=(/1/), ungriddedUBound=(/10/), rc=rc)
dstFieldA = ESMF_FieldCreate(grid, arrayspec, gridToFie ldMap=(/2/), &
ungriddedLBound=(/1/), ungriddedUBound=(/10/), rc=rc)

Using the previously computed routehandle, weakly congruent Fields can perform sparse matrix matmul.

call ESMF_FieldSMM(srcfieldA, dstFieldA, routehandle, rc=rc)

! release route handle

call ESMF_FieldSMMRelease(routehandle, rc=rc)

In the following discussion, we demonstrate how to set up a SMM routehandle between a pair of Fields that are
different in number of gridded dimensions and the size of those gridded dimensions. The source Field has a 1D
decomposition with 16 total elements; the destination Field has a 2D decomposition with 12 total elements. For ease
of understanding of the actual matrix calculation, a global indexing scheme is used.

distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/16/), &
indexflag=ESMF_INDEX_GLOBAL, &
regDecomp=(/4/), &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

grid = ESMF_GridCreate(distgrid=distgrid, &
indexflag=ESMF_INDEX_GLOBAL, &
nname="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

call ESMF_GridGetFieldBounds(grid, localDe=0, totalLBound=tlb, &
totalUBound=tub, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

create 1D src_farray, srcArray, and srcField

allocate(src_farray2(tlb(1):tub(1)) )
src_farray2 = lpe+1
srcArray = ESMF_ArrayCreate(distgrid, src_farray2, &
indexflag=ESMF_INDEX_GLOBAL, &
rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
!print *, lpe, '+', tlb, tub, '+', src_farray2

srcField = ESMF_FieldCreate(grid, srcArray, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
Create 2D dstField on the following distribution (numbers are the sequence indices):

\[\begin{array}{cccc}
+ & PET0 & PET1 & PET2 & PET3 \\
+--------+--------+--------+--------+
| | | | |
| 1 | 4 | 7 | 10 |
| | | | |
| 2 | 5 | 8 | 11 |
| | | | |
| 3 | 6 | 9 | 12 |
+--------+--------+--------+--------+
\]

! Create the destination Grid

dstGrid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/3,4/), &
  indexflag = ESMF_INDEX_GLOBAL, &
  regDecomp = (/1,4/), &
  rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

dstField = ESMF_FieldCreate(dstGrid, typekind=ESMF_TYPEKIND_R4, &
  indexflag=ESMF_INDEX_GLOBAL, &
  rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

Perform sparse matrix multiplication \( dst_i = M_{i,j} \times src_j \) First setup routehandle from source Field to destination Field with prescribed factorList and factorIndexList.

The sparse matrix is of size 12x16, however only the following entries are filled:

\[
M(3,1) = 0.1 \\
M(3,10) = 0.4 \\
M(8,2) = 0.25 \\
M(8,16) = 0.5 \\
M(12,1) = 0.3 \\
M(12,16) = 0.7 \\
\]

By the definition of matrix calculation, the 8th element on PET2 in the dstField equals to 0.25*srcField(2) + 0.5*srcField(16) = 0.25*1+0.5*4=2.25 For simplicity, we will load the factorList and factorIndexList on PET 0 and 1, the SMMStore engine will load balance the parameters on all 4 PETs internally for optimal performance.

if(lpe == 0) then
  allocate(factorList(3), factorIndexList(2,3))
  factorList=(/0.1,0.4,0.25/)
  factorIndexList(1,:)=(/1,10,2/)
  factorIndexList(2,:)=(/3,3,8/)
call ESMF_FieldSMMStore(srcField, dstField, routehandle=routehandle, &
factorList=factorList, factorIndexList=factorIndexList, rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
else if (lpe == 1) then
allocate(factorList(3), factorIndexList(2,3))
factorList=(/0.5,0.3,0.7/)
factorIndexList(1,:)=(/16,1,16/)
factorIndexList(2,:)=(/8,12,12/)
call ESMF_FieldSMMStore(srcField, dstField, routehandle=routehandle, &
factorList=factorList, factorIndexList=factorIndexList, rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
else
call ESMF_FieldSMMStore(srcField, dstField, routehandle=routehandle, &
rc=localrc)
if (localrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
! 2. use precomputed routehandle to perform SMM
call ESMF_FieldSMM(srcfield, dstField, routehandle=routehandle, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

25.3.33 Field Halo solving a domain decomposed heat transfer problem

ESMF_FieldHalo() interface can be used to perform halo update of a Field. This eases communication programming from a user perspective. By definition, user program only needs to update locally owned exclusive region in each domain, then call FieldHalo to communicate the values in the halo region from/to neighboring domain elements. In this example, we solve a 1D heat transfer problem: \( u_t = \alpha^2 u_{xx} \) with the initial condition \( u(0, x) = 20 \) and boundary conditions \( u(t, 0) = 10, u(t, 1) = 40 \). The temperature field \( u \) is represented by a ESMF_Field. A finite difference explicit time stepping scheme is employed. During each time step, FieldHalo update is called to communicate values in the halo region to neighboring domain elements. The steady state (as \( t \to \infty \)) solution is a linear temperature profile along \( x \). The numerical solution is an approximation of the steady state solution. It can be verified to represent a linear temperature profile.

Section 27.2.14 provides a discussion of the halo operation implemented in ESMF_Array.

! create 1D distgrid and grid decomposed according to the following diagram:

```plaintext
+------------+ +----------------+ +---------------+ +--------------+
| DE 0 | | | | DE 1 | | | | DE 2 | | | | DE 3 |
| 1 x 16 | | | | 1 x 16 | | | | 1 x 16 | | | | 1 x 16 |
+------------+ +----------------+ +---------------+ +--------------+
```

distgrid = ESMF_DistGridCreate(minIndex=(/1/), maxIndex=(/npx/), &
regDecomp=(/4/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

grid = ESMF_GridCreate(distgrid=distgrid, name="grid", rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! set up initial condition and boundary conditions of the
! temperature Field
if(lpe == 0) then
allocate(fptr(17), tmp_farray(17))

enddo
! release the halo routehandle
call ESMF_FieldHaloRelease(routehandle, rc=rc)

25.4 Restrictions and Future Work

1. **CAUTION:** It depends on the specific entry point of `ESMF_FieldCreate()` used during Field creation, which Fortran operations are supported on the Fortran array pointer `farrayPtr`, returned by `ESMF_FieldGet()`. Only if the `ESMF_FieldCreate()` from pointer variant was used, will the returned `farrayPtr` variable contain the original bounds information, and be suitable for the Fortran `deallocate()` call. This limitation is a direct consequence of the Fortran 95 standard relating to the passing of array arguments.

2. **No mathematical operators.** The Fields class does not currently support advanced operations on fields, such as differential or other mathematical operators.

3. **No vector Fields.** ESMF does not currently support storage of multiple vector Field components in the same Field component, although that support is planned. At this time users need to create a separate Field object to represent each vector component.

25.5 Design and Implementation Notes

1. Some methods which have a Field interface are actually implemented at the underlying Grid or Array level; they are inherited by the Field class. This allows the user API (Application Programming Interface) to present functions at the level which is most consistent to the application without restricting where inside the ESMF the actual implementation is done.

2. The Field class is implemented in Fortran, and as such is defined inside the framework by a Field derived type and a set of subprograms (functions and subroutines) which operate on that derived type. The Field class itself is very thin; it is a container class which groups a Grid and an Array object together.

3. Fields follow the framework-wide convention of the *unison* creation and operation rule: All PETs which are part of the currently executing VM must create the same Fields at the same point in their execution. Since an early user request was that global object creation not impose the overhead of a barrier or synchronization point, Field creation does no inter-PET communication. For this to work, each PET must query the total number of PETs in this VM, and which local PET number it is. It can then compute which DE(s) are part of the local decomposition, and any global information can be computed in unison by all PETs independently of the others. In this way the overhead of communication is avoided, at the cost of more difficulty in diagnosing program bugs which result from not all PETs executing the same create calls.

4. Related to the item above, the user request to not impose inter-PET communication at object creation time means that requirement FLD 1.5.1, that all Fields will have unique names, and if not specified, the framework will generate a unique name for it, is difficult or impossible to support. A part of this requirement has been implemented; a unique object counter is maintained in the Base object class, and if a name is not given at create time a name such as "Field003" is generated which is guaranteed to not be repeated by the framework. However, it is impossible to error check that the user has not replicated a name, and it is possible under certain conditions that if not all PETs have created the same number of objects, that the counters on different PETs may not stay synchronized. This remains an open issue.
25.6 Class API

25.6.1 ESMF_FieldAssignment(=) - Field assignment

INTERFACE:

    interface assignment(=)
    field1 = field2
    end interface

ARGUMENTS:

    type(ESMF_Field) :: field1
    type(ESMF_Field) :: field2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign field1 as an alias to the same ESMF Field object in memory as field2. If field2 is invalid, then field1 will be equally invalid after the assignment.

The arguments are:

field1 The ESMF_Field object on the left hand side of the assignment.
field2 The ESMF_Field object on the right hand side of the assignment.

---

25.6.2 ESMF_FieldOperator(==) - Field equality operator

INTERFACE:

    interface operator(==)
    if (field1 == field2) then ... endif
    OR
    result = (field1 == field2)
    end interface

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_Field), intent(in) :: field1
    type(ESMF_Field), intent(in) :: field2
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether field1 and field2 are valid aliases to the same ESMF Field object in memory. For a more general comparison of two ESMF Fields, going beyond the simple alias test, the ESMF_FieldMatch() function (not yet implemented) must be used.

The arguments are:

field1  The ESMF_Field object on the left hand side of the equality operation.
field2  The ESMF_Field object on the right hand side of the equality operation.

25.6.3 ESMF_FieldOperator(/=) - Field not equal operator

INTERFACE:

```
interface operator(/=)
  if (field1 /= field2) then ... endif
  OR
  result = (field1 /= field2)
end interface
```

RETURN VALUE:

```
logical :: result
```

ARGUMENTS:

```
type(ESMF_Field), intent(in) :: field1
type(ESMF_Field), intent(in) :: field2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether field1 and field2 are not valid aliases to the same ESMF Field object in memory. For a more general comparison of two ESMF Fields, going beyond the simple alias test, the ESMF_FieldMatch() function (not yet implemented) must be used.

The arguments are:
The ESMF_Field object on the left hand side of the non-equality operation.

The ESMF_Field object on the right hand side of the non-equality operation.

25.6.4 ESMF_FieldCopy - Copy data from one Field object to another

INTERFACE:

    subroutine ESMF_FieldCopy(fieldOut, fieldIn, rc)

ARGUMENTS:

    type(ESMF_Field), intent(inout) :: fieldOut
    type(ESMF_Field), intent(in) :: fieldIn

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

DESCRIPTION:

Copy data from one ESMF_Field object to another.

The arguments are:

fieldOut ESMF_Field object into which to copy the data. The incoming fieldOut must already references a matching memory allocation.

fieldIn ESMF_Field object that holds the data to be copied.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.5 ESMF_FieldCreate - Create a Field from Grid and typekind

INTERFACE:

    ! Private name; call using ESMF_FieldCreate()
    function ESMF_FieldCreateGridTKR(grid, typekind, &
               indexflag, staggerloc, gridToFieldMap, ungriddedLBound, ungriddedUBound, &
               totalLWidth, totalUWidth, name, rc)

RETURN VALUE:

    type(ESMF_Field) :: ESMF_FieldCreateGridTKR

ARGUMENTS:
type (ESMF_Grid), intent(in) :: grid
type (ESMF_TypeKind_Flag), intent(in) :: typekind

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_Index_Flag), intent(in), optional :: indexflag
type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.4.

The arguments are:

grid ESMF_Grid object.
typekind The typekind of the Field.

[indexflag] Indicate how DE-local indices are defined. By default each DE’s exclusive region is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated Grid. See section 50.2.22 for a list of valid indexflag options. The default indexflag value is the one stored in then ESMF_Grid object. Currently it is erroneous to specify an indexflag different from the one stored in the ESMF_Grid object. The default value is ESMF_INDEXFLAG_DELOCAL.

[staggerloc] Stagger location of data in grid cells. For valid predefined values see section 50.2.22. To create a custom stagger location see section 30.3.22. The default value is ESMF_STAGGERLOC_CENTER.

[gridToFieldMap] List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.
[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

[totalLWidth] Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[totalUWidth] Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.6 ESMF_FieldCreate - Create a Field from Grid and ArraySpec

**INTERFACE:**

```plaintext
! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateGridArraySpec(grid, arrayspec, &
   indexflag, staggerloc, gridToFieldMap, ungriddedLBound, &
   ungriddedUBound, totalLWidth, totalUWidth, name, rc)
```

**RETURN VALUE:**

```plaintext
type(ESMF_Field) :: ESMF_FieldCreateGridArraySpec
```

**ARGUMENTS:**

```plaintext
type(ESMF_Grid), intent(in) :: grid
type(ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Index_Flag), intent(in), optional :: indexflag
type(ESMF_StaggerLoc), intent(in), optional :: staggerloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc
```

**STATUS:**

315
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.5.

The arguments are:

- **grid** ESMF_Grid object.
- **arrayspec** Data type and kind specification.
- **[indexflag]** Indicate how DE-local indices are defined. By default each DE’s exclusive region is placed to start at the local index space origin, i.e. \((1, 1, \ldots, 1)\). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated Grid. See section 50.25 for a list of valid indexflag options. The default indexflag value is the one stored in then ESMF_Grid object. Currently it is erroneous to specify an indexflag different from the one stored in the ESMF_Grid object. The default value is ESMF_INDEXFLAG_DELOCAL.

integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Field. This version of creation assumes the data exists already and is being passed in through an ESMF_Array. For an example and associated documentation using this method see section 25.3.6.

The arguments are:

grid ESMF_Grid object.
array ESMF_Array object.

[datacopyflag] Indicates whether to copy the contents of the array or reference it directly. For valid values see 50.12 The default is ESMF_DATACOPY_REFERENCE.
Stagger location of data in grid cells. For valid predefined values see section 30.2.6. To create a custom stagger location see section 30.3.22. The default value is ESMF_STAGGERLOC_CENTER.

List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

Field name.

Return code; equals ESMF_SUCCESS if there are no errors.

25.6.8 ESMF_FieldCreate - Create a Field from Grid and Fortran array

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateGridData<rank><type><kind>(grid, &
farray, indexflag, datacopyflag, staggerloc, &
gridToFieldMap, ungriddedLBound, ungriddedUBound, &
totalLWidth, totalUWidth, name, rc)
RETURN VALUE:

```fortran
  type(ESMF_Field) :: ESMF_FieldCreateGridData<rank><type><kind>
```

ARGUMENTS:

```fortran
  type(ESMF_Grid), intent(in) :: grid
  <type> (ESMF_KIND_<kind>),intent(in), target :: farray(<rank>)
  type(ESMF_Index_Flag), intent(in) :: indexflag
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
  type(ESMF_StaggerLoc), intent(in), optional :: staggerloc
  integer, intent(in), optional :: gridToFieldMap(:)
  integer, intent(in), optional :: ungriddedLBound(:)
  integer, intent(in), optional :: ungriddedUBound(:)
  integer, intent(in), optional :: totalLWidth(:)
  integer, intent(in), optional :: totalUWidth(:)
  character (len=*), intent(in), optional :: name
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Field from a fortran data array and ESMF_Grid. The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed. For examples and associated documentations using this method see sections 25.3.10, 25.3.12, 25.3.13, 25.3.14, and 25.3.9.

The arguments are:

- **grid** ESMF_Grid object.
- **farray** Native fortran data array to be copied/referenced in the Field. The Field dimension (dimCount) will be the same as the dimCount for the farray.
- **indexflag** Indicate how DE-local indices are defined. See section 50.2.5 for a list of valid indexflag options. Currently it is erroneous to specify an indexflag different from the one stored in the ESMF_Grid object.
- **[datacopyflag]** Whether to copy the contents of the farray or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.
- **[staggerloc]** Stagger location of data in grid cells. For valid predefined values see section 50.2.6. To create a custom stagger location see section 30.3.22. The default value is ESMF_STAGGERLOC_CENTER.
- **[gridToFieldMap]** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farray rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farray dimensions less the
total (distributed + undistributed) dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the farray. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

[totalLWidth] Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the farray. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the farray. That is, for each gridded dimension the farray size should be \( \max(\text{totalLWidth} + \text{totalUWidth} + \text{computationalCount}, \text{exclusiveCount}) \).

[totalUWidth] Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the farray. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the farray. That is, for each gridded dimension the farray size should be \( \max(\text{totalLWidth} + \text{totalUWidth} + \text{computationalCount}, \text{exclusiveCount}) \).

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.9 ESMF_FieldCreate - Create a Field from Grid and Fortran array pointer

INTERFACE:

! Private name; call using ESMF_FieldCreate() function ESMF_FieldCreateGridDataPtr<rank><type><kind>(grid, & farrayPtr, datacopyflag, staggerloc, gridToFieldMap, & totalLWidth, totalUWidth, name, rc)

RETURN VALUE:

\[
\text{type}(\text{ESMF_Field}) \,:=\ ESMF_FieldCreateGridDataPtr<\text{rank}><\text{type}><\text{kind}>
\]

ARGUMENTS:
type(ESMF_Grid), intent(in) :: grid
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
<type> (ESMF_StaggerLoc), intent(in), optional :: staggerloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: totalLWidth(:)
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Field from a fortran data pointer and ESMF_Grid. The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

For examples and associated documentations using this method see section 25.3.11, 25.3.12, 25.3.13, 25.3.14, and 25.3.9.

The arguments are:

grid  ESMF_Grid object.

farrayPtr  Native fortran data pointer to be copied/referenced in the Field. The Field dimension (dimCount) will be the same as the dimCount for the farrayPtr.

[datacopyflag]  Whether to copy the contents of the farrayPtr or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

[staggerloc]  Stagger location of data in grid cells. For valid predefined values see section 30.2.6. To create a custom stagger location see section 30.3.22. The default value is ESMF_STAGGERLOC_CENTER.

[gridToFieldMap]  List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the farrayPtr in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farrayPtr rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farrayPtr dimensions less the total (distributed + undistributed) dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the farrayPtr. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

[totalLWidth]  Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the farrayPtr. Values default
to 0. If values for totalLWidth are specified they must be reflected in the size of the farrayPtr. That is, for each gridded dimension the farrayPtr size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

[totalUWidth] Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the farrayPtr. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the farrayPtr. That is, for each gridded dimension the farrayPtr size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.10 ESMF_FieldCreate - Create a Field from LocStream and typekind

INTERFACE:

```fortran
! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateLSTKR(locstream, typekind, &
    gridToFieldMap, ungriddedLBound, ungriddedUBound, &
    name, rc)
```

RETURN VALUE:

- `type(ESMF_Field) :: ESMF_FieldCreateLSTKR`

ARGUMENTS:

- `type(ESMF_LocStream), intent(in) :: locstream`
- `type(ESMF_TypeKind_Flag),intent(in) :: typekind`
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --`
  - `integer, intent(in), optional :: gridToFieldMap(:)`
  - `integer, intent(in), optional :: ungriddedLBound(:)`
  - `integer, intent(in), optional :: ungriddedUBound(:)`
  - `character (len=*), intent(in), optional :: name`
  - `integer, intent(out), optional :: rc`

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.15.

The arguments are:

- `locstream` ESMF_LocStream object.
- `typekind` The typekind of the Field.
[gridToFieldMap] List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.11 ESMF_FieldCreate - Create a Field from LocStream and ArraySpec

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateLSArraySpec(locstream, arrayspec, &
    gridToFieldMap, ungriddedLBound, ungriddedUBound, &
    name, rc)

RETURN VALUE:

    type(ESMF_Field) :: ESMF_FieldCreateLSArraySpec

ARGUMENTS:

    type(ESMF_LocStream), intent(in) :: locstream
    type(ESMF_ArraySpec), intent(in) :: arrayspec
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: gridToFieldMap(:)
    integer, intent(in), optional :: ungriddedLBound(:)
    integer, intent(in), optional :: ungriddedUBound(:)
    character (len=*) , intent(in), optional :: name
    integer, intent(out), optional :: rc
DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.16.

The arguments are:

- **locstream** ESMF_LocStream object.
- **arrayspec** Data type and kind specification.
- **[gridToFieldMap]** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

- **[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

- **[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

- **[name]** Field name.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.12 ESMF_FieldCreate - Create a Field from LocStream and Array

INTERFACE:

```fortran
! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateLSArray(locstream, array, &
  datacopyflag, gridToFieldMap, ungriddedLBound, ungriddedUBound, &
  name, rc)

RETURN VALUE:

  type(ESMF_Field) :: ESMF_FieldCreateLSArray
```

324
ARGUMENTS:

```
type(ESMF_LocStream), intent(in) :: locstream
type(ESMF_Array), intent(in) :: array
```

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
```
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
character (len =*), intent(in), optional :: name
integer, intent(out), optional :: rc
```

DESCRIPTION:

Create an ESMF_Field. This version of creation assumes the data exists already and is being passed in through an ESMF_Array. For an example and associated documentation using this method see section 25.3.6.

The arguments are:

- **locstream** ESMF_LocStream object.
- **array** ESMF_Array object.

**[datacopyflag]** Indicates whether to copy the contents of the array or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

**[gridToFieldMap]** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

**[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[name]** Field name.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
25.6.13  ESMF_FieldCreate - Create a Field from LocStream and Fortran array

INTERFACE:

    ! Private name; call using ESMF_FieldCreate()
    function ESMF_FieldCreateLSData<rank><type><kind>(locstream, farray, &
    indexflag, datacopyflag, gridToFieldMap, ungriddedLBound, &
    ungriddedUBound, name, rc)

RETURN VALUE:

    type(ESMF_Field) :: ESMF_FieldCreateLSData<rank><type><kind>

ARGUMENTS:

    type(ESMF_LocStream), intent(in) :: locstream
    <type> (ESMF_KIND_<kind>),intent(in), target :: farray(<rank>)
    type(ESMF_Index_Flag), intent(in) :: indexflag
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
    integer, intent(in), optional :: gridToFieldMap(:)
    integer, intent(in), optional :: ungriddedLBound(:)
    integer, intent(in), optional :: ungriddedUBound(:)
    character (len=*) , intent(in), optional :: name
    integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field from a fortran data array and ESMF_LocStream. The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.

The arguments are:

    locstream  ESMF_LocStream object.
    farray  Native fortran data array to be copied/referenced in the Field The Field dimension (dimCount) will be the same as the dimCount for the farray.
    indexflag  Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.
    [datacopyflag]  Whether to copy the contents of the farray or reference directly. For valid values see 50.12 The default is ESMF_DATACOPY_REFERENCE.
    [gridToFieldMap]  List with number of elements equal to the locstream’s dimCount. The list elements map each dimension of the locstream to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the locstream's dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farray rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farray dimensions less the total (distributed + undistributed) dimensions in the locstream.
Unlocstreamed dimensions must be in the same order they are stored in the farray. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than locstream dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than locstream dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.14 ESMF_FieldCreate - Create a Field from LocStream and Fortran array pointer

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateLSDataPtr<rank><type><kind> (locstream, &
farrayPtr, datacopyflag, gridToFieldMap, &
name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateLSDataPtr<rank><type><kind>

ARGUMENTS:

type(ESMF_LocStream), intent(in) :: locstream
<typename (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc
DESCRIPTION:

Create an ESMF_Field from a fortran data pointer and ESMF_LocStream. The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The arguments are:

**locstream** ESMF_LocStream object.

**farrayPtr** Native fortran data pointer to be copied/referenced in the Field. The Field dimension (dimCount) will be the same as the dimCount for the farrayPtr.

**[datacopyflag]** Whether to copy the contents of the farrayPtr or reference it directly. For valid values see ESMF_DATACOPY. The default is ESMF_DATACOPY_REFERENCE.

**[gridToFieldMap]** List with number of elements equal to the locstream's dimCount. The list elements map each dimension of the locstream to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the locstream's dimensions against the lowest dimensions of the farrayPtr in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farrayPtr rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farrayPtr dimensions less the total (distributed + undistributed) dimensions in the locstream. Unlocstreamed dimensions must be in the same order they are stored in the farrayPtr. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

**[name]** Field name.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.15  ESMF_FieldCreate - Create a Field from Mesh and typekind

INTERFACE:

```fortran
! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateMeshTKR(mesh, typekind, &
   meshloc, gridToFieldMap, ungriddedLBound, ungriddedUBound, &
   name, rc)

RETURN VALUE:

   type(ESMF_Field) :: ESMF_FieldCreateMeshTKR

ARGUMENTS:
```
type (ESMF_Mesh), intent(in) :: mesh
type (ESMF_TypeKind_Flag), intent(in) :: typekind

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_MeshLoc), intent(in), optional :: meshloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.17.

The arguments are:

mesh ESMF_Mesh object.
typekind The typekind of the Field.

[meshloc] The part of the Mesh on which to build the Field. For valid predefined values see Section 50.37. If not set, defaults to ESMF_MESHLOC_NODE.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.16 ESMF_FieldCreate - Create a Field from Mesh and ArraySpec

INTERFACE:
Public name; call using ESMF_FieldCreate ()

function ESMF_FieldCreateMeshArraySpec (mesh, arrayspec, &
    meshloc, gridToFieldMap, ungriddedLBound, ungriddedUBound, &
    name, rc)

RETURN VALUE:

type (ESMF_Field) :: ESMF_FieldCreateMeshArraySpec

ARGUMENTS:

type (ESMF_Mesh), intent (in) :: mesh

type (ESMF_ArraySpec), intent (in) :: arrayspec

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type (ESMF_MeshLoc), intent (in), optional :: meshloc
    integer, intent (in), optional :: gridToFieldMap(:)
    integer, intent (in), optional :: ungriddedLBound(:)
    integer, intent (in), optional :: ungriddedUBound(:)
    character (len=*), intent (in), optional :: name
    integer, intent (out), optional :: rc

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.18 and 25.3.20.

The arguments are:

mesh ESMF_Mesh object.

arrayspec Data type and kind specification.

[meshloc] The part of the Mesh on which to build the Field. For valid predefined values see Section 50.37. If not set, defaults to ESMF_MESHLOC_NODE.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.
[name]  Field name.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

25.6.17  ESMF_FieldCreate - Create a Field from Mesh and Array

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateMeshArray(mesh, array, &
   datacopyflag, meshloc, &
   gridToFieldMap, ungriddedLBound, ungriddedUBound, &
   name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateMeshArray

ARGUMENTS:

type(ESMF_Mesh), intent(in) :: mesh
   type(ESMF_Array), intent(in) :: array
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
   type(ESMF_MeshLoc), intent(in), optional :: meshloc
   integer, intent(in), optional :: gridToFieldMap(:)
   integer, intent(in), optional :: ungriddedLBound(:)
   integer, intent(in), optional :: ungriddedUBound(:)
   character (len = *), intent(in), optional :: name
   integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field. This version of creation assumes the data exists already and is being passed in through an ESMF_Array. For an example and associated documentation using this method see section 25.3.19.

The arguments are:

mesh  ESMF_Mesh object.

array  ESMF_Array object.

[datacopyflag] Indicates whether to copy the contents of the array or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

[ meshloc ] The part of the Mesh on which to build the Field. For valid predefined values see Section 50.37. If not set, defaults to ESMF_MESHLOC_NODE.
[gridToFieldMap] List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.18 ESMF_FieldCreate - Create a Field from Mesh and Fortran array

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateMeshData<rank><type><kind>(mesh, &
farray, indexflag, datacopyflag, meshloc, &
gridToFieldMap, ungriddedLBound, ungriddedUBound, name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateMeshData<rank><type><kind>

ARGUMENTS:

type(ESMF_Mesh), intent(in) :: mesh
<type> (ESMF_KIND_<kind>), intent(in), target :: farray<rank>)
type(ESMF_Index_Flag), intent(in) :: indexflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_MeshLoc), intent(in), optional :: meshloc
integer, intent(in), optional :: gridToFieldMap(:)
Create an ESMF_Field from a fortran data array and ESMF_Mesh. The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.

The arguments are:

**mesh** ESMF_Mesh object.

**farray** Native fortran data array to be copied/referenced in the Field. The Field dimension (dimCount) will be the same as the dimCount for the farray.

**indexflag** Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

**[datacopyflag]** Whether to copy the contents of the farray or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

**[meshloc]** The part of the Mesh on which to build the Field. For valid predefined values see Section 50.37. If not set, defaults to ESMF_MESHLOC_NODE.

**gridToFieldMap** List with number of elements equal to the mesh’s dimCount. The list elements map each dimension of the mesh to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the mesh’s dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1, 2, 3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farray rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farray dimensions less the total (distributed + undistributed) dimensions in the mesh. Unmeshed dimensions must be in the same order they are stored in the farray. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

**[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than mesh dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

**[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than mesh dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

**[name]** Field name.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
25.6.19 ESMF_FieldCreate - Create a Field from Mesh and Fortran array pointer

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateMeshDataPtr<rank><type><kind>(mesh, &
farrayPtr, datacopyflag, meshloc, gridToFieldMap, &
name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateMeshDataPtr<rank><type><kind>

ARGUMENTS:

type(ESMF_Mesh), intent(in) :: mesh
<type> (ESMF_KIND_<kind>),pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_MeshLoc), intent(in), optional :: meshloc
gridToFieldMap(:)
character (len=*
integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field from a fortran data pointer and ESMF_Mesh. The fortran data pointer inside
ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the
ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility
over memory management.

The arguments are:

mesh ESMF_Mesh object.
farrayPtr Native fortran data pointer to be copied/referenced in the Field The Field dimension (dimCount) will be
the same as the dimCount for the farrayPtr.

[datacopyflag] Whether to copy the contents of the farrayPtr or reference it directly. For valid values see Section 50.12
The default is ESMF_DATACOPY_REFERENCE.

[meshloc] The part of the Mesh on which to build the Field. For valid predefined values see Section 50.37 If not set,
defaults to ESMF_MESHLOC_NODE.

[gridToFieldMap] List with number of elements equal to the mesh’s dimCount. The list elements map each dimen-
sion of the mesh to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension
index. The default is to map all of the mesh’s dimensions against the lowest dimensions of the farrayPtr
in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be
greater than or equal to one and smaller than or equal to the farrayPtr rank. It is erroneous to specify the
same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total
farrayPtr dimensions less the total (distributed + undistributed) dimensions in the mesh. Unmeshed dimensions must be in the same order they are stored in the farrayPtr. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.20 ESMF_FieldCreate - Create a Field from XGrid and typekind

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateXGTKR(xgrid, typekind, &
  xgridside, gridindex, &
  gridToFieldMap, ungriddedLBound, ungriddedUBound, &
  name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateXGTKR

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid

type(ESMF_TypeKind_Flag), intent(in) :: typekind

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
character (len=*) ,intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.15.

The arguments are:

xgrid ESMF_XGrid object.

typekind The typekind of the Field.
[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridSide is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (1,2,3,...). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the XGrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular XGrid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.21 ESMF_FieldCreate - Create a Field from XGrid and ArraySpec

INTERFACE:

! Private name; call using ESMF_FieldCreate() 
function ESMF_FieldCreateXGArraySpec(xgrid, arrayspec, & 
xgridside, gridindex, & 
gridToFieldMap, ungriddedLBound, ungriddedUBound, & 
name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateXGArraySpec

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid

type(ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridSide
  integer, intent(in), optional :: gridIndex
  integer, intent(in), optional :: gridToFieldMap(:)
  integer, intent(in), optional :: ungriddedLBound(:)
  integer, intent(in), optional :: ungriddedUBound(:)
character (len=*) , intent(in), optional :: name
  integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field and allocate space internally for an ESMF_Array. Return a new ESMF_Field. For an example and associated documentation using this method see section 25.3.16.

The arguments are:

**xgrid** ESMF_XGrid object.

**arrayspec** Data type and kind specification.

[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the grid. If the Field dimCount is less than the XGrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular XGrid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
25.6.22  ESMF_FieldCreate - Create a Field from XGrid and Array

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateXGArray(xgrid, array, &
datacopyflag, xgridside, gridindex, &
gridToFieldMap, ungriddedLBound, ungriddedUBound, &
name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateXGArray

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid

type(ESMF_Array), intent(in) :: array

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag

type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside

integer, intent(in), optional :: gridindex

integer, intent(in), optional :: gridToFieldMap(:)

integer, intent(in), optional :: ungriddedLBound(:)

integer, intent(in), optional :: ungriddedUBound(:)

character (len =* ), intent(in), optional :: name

integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field. This version of creation assumes the data exists already and is being passed in through an ESMF_Array. For an example and associated documentation using this method see section 25.3.6.

The arguments are:

xgrid  ESMF_XGrid object.

array  ESMF_Array object.

[datacopyflag] Indicates whether to copy the contents of the array or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridSide is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the
dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the XGrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular XGrid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.23 ESMF_FieldCreate - Create a Field from XGrid and Fortran array

**INTERFACE:**

```fortran
! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateXGData<rank><type><kind>(xgrid, &
farray, indexflag, datacopyflag, xgridside, gridindex, &
gridToFieldMap, ungriddedLBound, ungriddedUBound, name,&
rc)
```

**RETURN VALUE:**

```fortran
type(ESMF_Field) :: ESMF_FieldCreateXGData<rank><type><kind>
```

**ARGUMENTS:**

```fortran
type(ESMF_XGrid), intent(in) :: xgrid
<type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)
type(ESMF_Index_Flag), intent(in) :: indexflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
character (len=*&), intent(in), optional :: name
integer, intent(out), optional :: rc
```
DESCRIPTION:

Create an ESMF_Field from a fortran data array and ESMF_Xgrid. The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.

The arguments are:

**xgrid**  ESMF_XGrid object.

**farray**  Native fortran data array to be copied/referenced in the Field The Field dimension (dimCount) will be the same as the dimCount for the farray.

**indexflag**  Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

**[datacopyflag]**  Whether to copy the contents of the farray or reference directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

**[xgridside]**  Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

**[gridindex]**  If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

**[gridToFieldMap]**  List with number of elements equal to the xgrid's dimCount. The list elements map each dimension of the xgrid to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the xgrid's dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farray rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farray dimensions less the total (distributed + undistributed) dimensions in the xgrid. Unxgridded dimensions must be in the same order they are stored in the farray. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Xgrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Xgrid dimension will be replicating the Field across the DEs along this direction.

**[ungriddedLBound]**  Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than xgrid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

**[ungriddedUBound]**  Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than xgrid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the farray.

**[name]**  Field name.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.
25.6.24  ESMF_FieldCreate - Create a Field from XGrid and Fortran array pointer

INTERFACE:

! Private name; call using ESMF_FieldCreate()
function ESMF_FieldCreateXGDataPtr<rank><type><kind> (xgrid, farrayPtr, &
datacopyflag, xgridside, &
gridindex, gridToFieldMap, name, rc)

RETURN VALUE:

type(ESMF_Field) :: ESMF_FieldCreateXGDataPtr<rank><type><kind>

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

Create an ESMF_Field from a fortran data pointer and ESMF_Xgrid. The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The arguments are:

xgrid  ESMF_XGrid object.

farrayPtr  Native fortran data pointer to be copied/referenced in the Field. The Field dimension (dimCount) will be the same as the dimCount for the farrayPtr.

[datacopyflag]  Whether to copy the contents of the farrayPtr or reference it directly. For valid values see ESMF_DATACOPY_REFERENCE. The default is ESMF_DATACOPY_REFERENCE.

[xgridside]  Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex]  If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[gridToFieldMap]  List with number of elements equal to the xgrid’s dimCount. The list elements map each dimension of the xgrid to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the xgrid’s dimensions against the lowest dimensions of the farrayPtr.
in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the farrayPtr rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total farrayPtr dimensions less the total (distributed + undistributed) dimensions in the xgrid. Unxgridded dimensions must be in the same order they are stored in the farrayPtr. Permutations of the order of dimensions are handled via individual communication methods. For example, an undistributed dimension can be remapped to a distributed dimension as part of the ESMF_ArrayRedist() operation. If the Field dimCount is less than the Xgrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Xgrid dimension will be replicating the Field across the DEs along this direction.

[name] Field name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.25 ESMF_FieldDestroy - Release resources associated with a Field

INTERFACE:

```fortran
subroutine ESMF_FieldDestroy(field, rc)
```

ARGUMENTS:

- `type(ESMF_Field), intent(inout) :: field`  
  The following arguments require argument keyword syntax (e.g. rc=rc).  
  `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Releases resources associated with the ESMF_Field. If an ESMF_Grid is associated with field, it will not be released. If field is not released with this call, it will be released by the automatic garbage collection facility in the scope of the Component that created field.

The arguments are:

- `field` ESMF_Field object.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.

25.6.26 ESMF_FieldEmptyComplete - Complete a Field from arrayspec

INTERFACE:
subroutine ESMF_FieldEmptyCompAS(field, arrayspec, &
  indexflag, gridToFieldMap, &
  ungriddedLBound, ungriddedUBound, totalLWidth, totalUWidth, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Complete an ESMF_Field and allocate space internally for an ESMF_Array based on arrayspec. The input ESMF_Field must have a status of ESMF_FIELDSTATUS_GRIDSET. After this call the completed ESMF_Field has a status of ESMF_FIELDSTATUS_COMPLETE.

The arguments are:

field The input ESMF_Field with a status of ESMF_FIELDSTATUS_GRIDSET.
arrayspec Data type and kind specification.
indexflag Indicate how DE-local indices are defined. By default each DE’s exclusive region is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated Grid. See section 50.25 for a list of valid indexflag options.
gridToFieldMap List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.
[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

totalLWidth Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

totalUWidth Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.27 ESMF_FieldEmptyComplete - Complete a Field from typekind

INTERFACE:

    ! Private name; call using ESMF_FieldEmptyComplete()
    subroutine ESMF_FieldEmptyCompleteTK(field, typekind, &
        indexflag, gridToFieldMap, &
        ungriddedLBound, ungriddedUBound, totalLWidth, totalUWidth, rc)

ARGUMENTS:

    type(ESMF_Field), intent(inout) :: field
    type(ESMF_TypeKind_Flag), intent(in) :: typekind
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Index_Flag), intent(in), optional :: indexflag
    integer, intent(in), optional :: gridToFieldMap(:)
    integer, intent(in), optional :: ungriddedLBound(:)
    integer, intent(in), optional :: ungriddedUBound(:)
    integer, intent(in), optional :: totalLWidth(:)
    integer, intent(in), optional :: totalUWidth(:)
    integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Complete an ESMF_Field and allocate space internally for an ESMF_Array based on typekind. The input ESMF_Field must have a status of ESMF_FIELDSTATUS_GRIDSET. After this call the completed ESMF_Field has a status of ESMF_FIELDSTATUS_COMPLETE.

For an example and associated documentation using this method see section 25.3.7.

The arguments are:

- **field** The input ESMF_Field with a status of ESMF_FIELDSTATUS_GRIDSET.

- **typekind** Data type and kind specification.

- **[indexflag]** Indicate how DE-local indices are defined. By default each DE’s exclusive region is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated Grid. See section 50.23 for a list of valid indexflag options.

- **[staggerloc]** Stagger location of data in grid cells. For valid predefined values see section 50.2. To create a custom stagger location see section 30.22. The default value is ESMF_STAGGERLOC_CENTER.

- **[gridToFieldMap]** List with number of elements equal to the grid’s dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid’s dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

- **[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

- **[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

- **[totalLWidth]** Lower bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

- **[totalUWidth]** Upper bound of halo region. The size of this array is the number of gridded dimensions in the Field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each grid- ded dimension the field size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.28 ESMF_FieldEmptyComplete - Complete a Field from Fortran array

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyComp<rank><type><kind>(field, &
farray, indexflag, datacopyflag, gridToFieldMap, &
ungriddedLBound, ungriddedUBound, totalLWidth, totalUWidth, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
<type> (ESMF_KIND_<kind>),intent(in), target :: farray(<rank>)
type(ESMF_Index_Flag), intent(in) :: indexflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Complete an ESMF_Field and allocate space internally for an ESMF_Array based on typekind. The input ESMF_Field must have a status of ESMF_FIELDSTATUS_GRIDSET. After this call the completed ESMF_Field has a status of ESMF_FIELDSTATUS_COMPLETE.

The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.

For an example and associated documentation using this method see section 25.3.8

The arguments are:

field The input ESMF_Field with a status of ESMF_FIELDSTATUS_GRIDSET. The ESMF_Field will have the same dimension (dimCount) as the rank of the farray.

farray Native fortran data array to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farray.
indexflag  Indicate how DE-local indices are defined. See section \ref{sec:DE-local indices} for a list of valid indexflag options.

[datcopyflag]  Indicates whether to copy the farray or reference it directly. For valid values see \ref{sec:copy flag}. The default is `ESMF_DATACOPY_REFERENCE`.

[gridToFieldMap]  List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the farray in sequence, i.e. `gridToFieldMap = (/1,2,3,.../)`. Unmapped farray dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound]  Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound]  Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

[totalLWidth]  Lower bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

[totalUWidth]  Upper bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

[rc]  Return code; equals `ESMF_SUCCESS` if there are no errors.

25.6.29 ESMF_FieldEmptyComplete - Complete a Field from Fortran array pointer

INTERFACE:

```fortran
! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompPtr<rank><type><kind>(field, &
farrayPtr, datcopyflag, gridToFieldMap, &
totalLWidth, totalUWidth, rc)
```

ARGUMENTS:
type(ESMF_Field), intent(inout) :: field
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Complete an ESMF_Field and allocate space internally for an ESMF_Array based on typekind. The input ESMF_Field must have a status of ESMF_FIELDSTATUS_GRIDSET. After this call the completed ESMF_Field has a status of ESMF_FIELDSTATUS_COMPLETE.

The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The arguments are:

field The input ESMF_Field with a status of ESMF_FIELDSTATUS_GRIDSET. The ESMF_Field will have the same dimension (dimCount) as the rank of the farrayPtr.
farrayPtr Native fortran data pointer to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farrayPtr.
[datacopyflag] Indicates whether to copy the farrayPtr or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.
[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the farrayPtr in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farrayPtr dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.
[totallLWidth] Lower bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totallWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totallWidth + totalUWidth + computationalCount, exclusiveCount ).
[totallUWidth] Upper bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max( totallWidth + totalUWidth + computationalCount, exclusiveCount ).
25.6.30  ESMF_FieldEmptyComplete - Complete a Field from Grid started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompGrid<rank><type><kind> (field, grid, &
farray, indexflag, datacopyflag, staggerloc, gridToFieldMap, &
ungriddedLBound, ungriddedUBound, totalLWidth, totalUWidth, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field

type(ESMF_Grid), intent(in) :: grid

<type> (ESMF_KIND_<kind>),intent(in), target :: farray(<rank>)

type(ESMF_Index_Flag), intent(in) :: indexflag

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag

type(ESMF_STAGGERLOC), intent(in), optional :: staggerloc

integer, intent(in), optional :: gridToFieldMap(:)

integer, intent(in), optional :: ungriddedLBound(:)

integer, intent(in), optional :: ungriddedUBound(:)

integer, intent(in), optional :: totalLWidth(:)

integer, intent(in), optional :: totalUWidth(:)

integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.

The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.

The arguments are:

field The ESMF_Field object to be completed and committed in this call. The field will have the same dimension (dimCount) as the rank of the farray.

grid The ESMF_Grid object to complete the Field.

farray Native fortran data array to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farray.
**indexflag**  Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

**[datacopyflag]** Indicates whether to copy the farray or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

**[staggerloc]** Stagger location of data in grid cells. For valid predefined values see section 50.2.6. To create a custom stagger location see section 50.3.22. The default value is ESMF_STAGGERLOC_CENTER.

**[gridToFieldMap]** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farray dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.

**[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[totalLWidth]** Lower bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

**[totalUWidth]** Upper bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ).

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

### 25.6.31 ESMF_FieldEmptyComplete - Complete a Field from Grid started with FieldEmptyCreate

**INTERFACE:**

```fortran
! Private name; call using ESMF_FieldEmptyComplete()
! subroutine ESMF_FieldEmptyCompGridPtr(rank)<type><kind>(field, grid, &
    farrayPtr, datacopyflag, staggerloc, gridToFieldMap, &
    totalLWidth, totalUWidth, rc)
```
ARGUMENTS:

```
type(ESMF_Field), intent(inout) :: field

type(ESMF_Grid), intent(in) :: grid

<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag

type(ESMF_STAGGERLOC), intent(in), optional :: staggerloc

integer, intent(in), optional :: gridToFieldMap(:)

integer, intent(in), optional :: totalLWidth(:)

integer, intent(in), optional :: totalUWidth(:)

integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.

The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The fortran data pointer inside ESMF_Field can be queried and deallocated when

The arguments are:

- **field**  The ESMF_Field object to be completed and committed in this call. The **field** will have the same dimension (dimCount) as the rank of the **farrayPtr**.

- **grid**  The ESMF_Grid object to complete the Field.

- **farrayPtr**  Native fortran data pointer to be copied/referenced in the **field**. The **field** dimension (dimCount) will be the same as the dimCount for the **farrayPtr**.

- **[datacopyflag]** Indicates whether to copy the **farrayPtr** or reference it directly. For valid values see [50.12](#). The default is ESMF_DATACOPY_REFERENCE.

- **[staggerloc]**  Stagger location of data in grid cells. For valid predefined values see section [30.2.6](#). To create a custom stagger location see section [30.3.22](#). The default value is ESMF_STAGGERLOC_CENTER.

- **[gridToFieldMap]**  List with number of elements equal to the **grid**'s dimCount. The list elements map each dimension of the **grid** to a dimension in the **farrayPtr** by specifying the appropriate **farrayPtr** dimension index. The default is to map all of the **grid**'s dimensions against the lowest dimensions of the **farrayPtr** in sequence, i.e. **gridToFieldMap** = ([1, 2, 3,...]). Unmapped **farrayPtr** dimensions are undistributed Field dimensions. All **gridToFieldMap** entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the Grid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the **gridToFieldMap** indicates that the particular Grid dimension will be replicating the Field across the DEs along this direction.
[totalLWidth] Lower bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[totalUWidth] Upper bound of halo region. The size of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.32 ESMF_FieldEmptyComplete - Complete a Field from LocStream started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompLS<rank><type><kind>(field, locstream, & farray, indexflag, datacopyflag, gridToFieldMap, & ungriddedLBound, ungriddedUBound, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_LocStream), intent(in) :: locstream
<type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)
type(ESMF_Index_Flag), intent(in) :: indexflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(out), optional :: rc

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call. The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed. The arguments are:

field The ESMF_Field object to be completed and committed in this call. The field will have the same dimension (dimCount) as the rank of the farray.

locstream The ESMF_LocStream object to complete the Field.
farray  Native fortran data array to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farray.

indexflag  Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

datacopyflag  Indicates whether to copy the farray or reference it directly. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

gridToFieldMap  List with number of elements equal to the locstream’s dimCount. The list elements map each dimension of the locstream to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the locstream’s dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farray dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

ungriddedLBound  Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than locstream dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

ungriddedUBound  Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than locstream dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

rc  Return code; equals ESMF_SUCCESS if there are no errors.

25.6.33 ESMF_FieldEmptyComplete - Complete a Field from LocStream started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompLSPtr<rank><type><kind>(field, locstream, &
farrayPtr, datacopyflag, gridToFieldMap, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_LocStream), intent(in) :: locstream
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(out), optional :: rc
DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.

The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not reallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The arguments are:

- **field** The ESMF_Field object to be completed and committed in this call. The field will have the same dimension (dimCount) as the rank of the farrayPtr.

- **locstream** The ESMF_LocStream object to complete the Field.

- **farrayPtr** Native fortran data pointer to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farrayPtr.

- **datacopyflag** Indicates whether to copy the farrayPtr or reference it directly. For valid values see [50.12](#). The default is ESMF_DATACOPY_REFERENCE.

- **gridToFieldMap** List with number of elements equal to the locstream's dimCount. The list elements map each dimension of the locstream to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the locstream's dimensions against the lowest dimensions of the farrayPtr in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farrayPtr dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the LocStream dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular LocStream dimension will be replicating the Field across the DEs along this direction.

- **rc** Return code; equals ESMF_SUCCESS if there are no errors.

### 25.6.34 ESMF_FieldEmptyComplete - Complete a Field from Mesh started with FieldEmptyCreate

INTERFACE:

```fortran
! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompMesh<rank><type><kind> (field, mesh, &
farray, indexflag, datacopyflag, meshloc, &
gridToFieldMap, ungriddedLBound, ungriddedUBound, rc)
```

ARGUMENTS:

```fortran
type(ESMF_Field), intent(inout) :: field

type(ESMF_Mesh), intent(in) :: mesh

<type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)

type(ESMF_Index_Flag), intent(in) :: indexflag

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
```

354
type(ESMF_MeshLoc), intent(in), optional :: meshloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(out), optional :: rc

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.
The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.
The arguments are:

field The ESMF_Field object to be completed and committed in this call. The field will have the same dimension (dimCount) as the rank of the farray.

mesh The ESMF_Mesh object to complete the Field.

farray Native fortran data array to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farray.

indexflag Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

[datacopyflag] Indicates whether to copy the farray or reference it directly. For valid values see 50.12 The default is ESMF_DATACOPY_REFERENCE.

[meshloc] Which part of the mesh to build the Field on. Can be set to either ESMF_MESHLOC_NODE or ESMF_MESHLOC_ELEMENT. If not set, defaults to ESMF_MESHLOC_NODE.

[gridToFieldMap] List with number of elements equal to the mesh's dimCount. The list elements map each dimension of the mesh to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the mesh's dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farray dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than Mesh dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than Mesh dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
25.6.35  ESMF_FieldEmptyComplete - Complete a Field from Mesh started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompMeshPtr<rank><type><kind>(field, mesh, &
farrayPtr, datacopyflag, meshloc, gridToFieldMap, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_Mesh), intent(in) :: mesh
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_MeshLoc), intent(in), optional :: meshloc
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(out), optional :: rc

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.
The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is
ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data
pointer in this case. This gives user more flexibility over memory management.
The arguments are:

field  The ESMF_Field object to be completed and committed in this call. The field will have the same dimension
(dimCount) as the rank of the farrayPtr.

mesh  The ESMF_Mesh object to complete the Field.

farrayPtr  Native fortran data pointer to be copied/referenced in the field. The field dimension (dimCount) will
be the same as the dimCount for the farrayPtr.

[datacopyflag] Indicates whether to copy the farrayPtr or reference it directly. For valid values see S0.12. The
default is ESMF_DATACOPY_REFERENCE.

[meshloc] Which part of the mesh to build the Field on. Can be set to either ESMF_MESHLOC_NODE or
ESMF_MESHLOC_ELEMENT. If not set, defaults to ESMF_MESHLOC_NODE.

[gridToFieldMap] List with number of elements equal to the mesh's dimCount. The list elements map each dimen-
sion of the mesh to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension
index. The default is to map all of the mesh's dimensions against the lowest dimensions of the farrayPtr in
sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farrayPtr dimensions are undistributed Field
dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal
to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field
dimCount is less than the Mesh dimCount then the default gridToFieldMap will contain zeros for the rightmost
entries. A zero entry in the gridToFieldMap indicates that the particular Mesh dimension will be replicating
the Field across the DEs along this direction.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
25.6.36  ESMF_FieldEmptyComplete - Complete a Field from XGrid started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompXG<rank><type><kind>(field, xgrid, &
  farray, indexflag, datacopyflag, xgridside, gridindex, &
  gridToFieldMap, &
  ungriddedLBound, ungriddedUBound, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
  type(ESMF_XGrid), intent(in) :: xgrid
  <type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)
  type(ESMF_Index_Flag), intent(in) :: indexflag

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
  type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
  integer, intent(in), optional :: gridindex
  integer, intent(in), optional :: gridToFieldMap()
  integer, intent(in), optional :: ungriddedLBound()
  integer, intent(in), optional :: ungriddedUBound()
  integer, intent(out), optional :: rc

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.
The fortran data pointer inside ESMF_Field can be queried but deallocating the retrieved data pointer is not allowed.
The arguments are:

field  The ESMF_Field object to be completed and committed in this call. The field will have the same dimension
       (dimCount) as the rank of the farray.

xgrid  The ESMF_XGrid object to complete the Field.

farray Native fortran data array to be copied/referenced in the field. The field dimension (dimCount) will be
       the same as the dimCount for the farray.

indexflag Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

[datacopyflag] Indicates whether to copy the farray or reference it directly. For valid values see 50.12 The default
               is ESMF_DATACOPY_REFERENCE.

[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B,
            or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridSide is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on
            that side to create the Field on. If not provided, defaults to 1.
[gridToFieldMap] List with number of elements equal to the xgrid’s dimCount. The list elements map each dimension of the xgrid to a dimension in the farray by specifying the appropriate farray dimension index. The default is to map all of the xgrid’s dimensions against the lowest dimensions of the farray in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farray dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the XGrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular XGrid dimension will be replicating the Field across the DEs along this direction.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than XGrid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than XGrid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.37 ESMF_FieldEmptyComplete - Complete a Field from XGrid started with FieldEmptyCreate

INTERFACE:

! Private name; call using ESMF_FieldEmptyComplete()
subroutine ESMF_FieldEmptyCompXGPtr<rank><type><kind>(field, xgrid, &
farrayPtr, xgridside, gridindex, &
datacopyflag, gridToFieldMap, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_XGrid), intent(in) :: xgrid
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(out), optional :: rc

DESCRIPTION:

This call completes an ESMF_Field allocated with the ESMF_FieldEmptyCreate() call.
The fortran data pointer inside ESMF_Field can be queried and deallocated when datacopyflag is ESMF_DATACOPY_REFERENCE. Note that the ESMF_FieldDestroy call does not deallocate the fortran data pointer in this case. This gives user more flexibility over memory management.

The arguments are:

field The ESMF_Field object to be completed and committed in this call. The field will have the same dimension (dimCount) as the rank of the farrayPtr.

xgrid The ESMF_XGrid object to complete the Field.

farrayPtr Native fortran data pointer to be copied/referenced in the field. The field dimension (dimCount) will be the same as the dimCount for the farrayPtr.

[datacopyflag] Indicates whether to copy the farrayPtr or reference it directly. For valid values see 50.12 The default is ESMF_DATACOPY_REFERENCE.

[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[gridToFieldMap] List with number of elements equal to the xgrid's dimCount. The list elements map each dimension of the xgrid to a dimension in the farrayPtr by specifying the appropriate farrayPtr dimension index. The default is to map all of the xgrid's dimensions against the lowest dimensions of the farrayPtr in sequence, i.e. gridToFieldMap = (/1,2,3,.../). Unmapped farrayPtr dimensions are undistributed Field dimensions. All gridToFieldMap entries must be greater than or equal to zero and smaller than or equal to the Field dimCount. It is erroneous to specify the same entry multiple times unless it is zero. If the Field dimCount is less than the XGrid dimCount then the default gridToFieldMap will contain zeros for the rightmost entries. A zero entry in the gridToFieldMap indicates that the particular XGrid dimension will be replicating the Field across the DEs along this direction.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.38 ESMF_FieldEmptyCreate - Create an empty Field

INTERFACE:

function ESMF_FieldEmptyCreate(name, rc)

RETURN VALUE:

   type(ESMF_Field) :: ESMF_FieldEmptyCreate

ARGUMENTS:

   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   character (len = *), intent(in), optional :: name
   integer, intent(out), optional :: rc

STATUS:

   359
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

This version of ESMF_FieldCreate builds an empty ESMF_Field and depends on later calls to add an ESMF_Grid and ESMF_Array to it. The empty ESMF_Field can be completed in one more step or two more steps by the ESMF_FieldEmptySet and ESMF_FieldEmptyComplete methods. Attributes can be added to an empty Field object. For an example and associated documentation using this method see section 25.3.8 and 25.3.7.

The arguments are:

- **[name]** Field name.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.39 ESMF_FieldEmptySet - Set a Grid in an empty Field

**INTERFACE:**

```fortran
! Private name; call using ESMF_FieldEmptySet()
subroutine ESMF_FieldEmptySetGrid(field, grid, StaggerLoc, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_Field), intent(inout) :: field
type(ESMF_Grid), intent(in) :: grid
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_STAGGERLOC), intent(in), optional :: StaggerLoc
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Set a grid and an optional staggerloc (default to center stagger ESMF_STAGGERLOC_CENTER) in a non-completed ESMF_Field. The ESMF_Field must not be completed for this to succeed. After this operation, the ESMF_Field contains the ESMF_Grid internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET or stays ESMF_FIELDSTATUS_GRIDSET.

For an example and associated documentation using this method see section 25.3.7.

The arguments are:

- **field** Empty ESMF_Field. After this operation, the ESMF_Field contains the ESMF_Grid internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET.
grid  ESMF_Grid to be set in the ESMF_Field.

[StaggerLoc] Stagger location of data in grid cells. For valid predefined values see section 30.2.6. To create a custom stagger location see section 30.5.22. The default value is ESMF_STAGGERLOC_CENTER.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.40  ESMF_FieldEmptySet - Set a Mesh in an empty Field

INTERFACE:

   ! Private name; call using ESMF_FieldEmptySet()
   subroutine ESMF_FieldEmptySetMesh(field, mesh, meshloc, rc)

ARGUMENTS:

   type(ESMF_Field), intent(inout) :: field
   type(ESMF_Mesh), intent(in) :: mesh
   type(ESMF_MeshLoc), intent(in), optional :: meshloc
   integer, intent(out), optional :: rc

DESCRIPTION:

Set a mesh and an optional meshloc (default to center stagger ESMF_MESHLOC_NODE) in a non-completed ESMF_Field. The ESMF_Field must not be completed for this to succeed. After this operation, the ESMF_Field contains the ESMF_Mesh internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET or stays ESMF_FIELDSTATUS_GRIDSET.

The arguments are:

field  Empty ESMF_Field. After this operation, the ESMF_Field contains the ESMF_Mesh internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET.

mesh  ESMF_Mesh to be set in the ESMF_Field.

[meshloc] Which part of the mesh to build the Field on. Can be set to either ESMF_MESHELOC_NODE or ESMF_MESHELOC_ELEMENT. If not set, defaults to ESMF_MESHELOC_NODE.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.41  ESMF_FieldEmptySet - Set a LocStream in an empty Field

INTERFACE:
subroutine ESMF_FieldEmptySetLocStream(field, locstream, rc)

ARGUMENTS:

  type(ESMF_Field), intent(inout) :: field
  type(ESMF_LocStream), intent(in) :: locstream

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

DESCRIPTION:

Set a ESMF_LocStream in a non-completed ESMF_Field. The ESMF_Field must not be completed for this to succeed. After this operation, the ESMF_Field contains the ESMF_LocStream internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET or stays ESMF_FIELDSTATUS_GRIDSET.

The arguments are:

field  Empty ESMF_Field. After this operation, the ESMF_Field contains the ESMF_LocStream internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET.

locstream  ESMF_LocStream to be set in the ESMF_Field.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

25.6.42  ESMF_FieldEmptySet - Set an XGrid in an empty Field

INTERFACE:

subroutine ESMF_FieldEmptySetXGrid(field, xgrid, xgridside, gridindex, rc)

ARGUMENTS:

  type(ESMF_Field), intent(inout) :: field
  type(ESMF_XGrid), intent(in) :: xgrid

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
  integer, intent(in), optional :: gridindex
  integer, intent(out), optional :: rc

DESCRIPTION:

Set a xgrid and optional xgridside (default to balanced side ESMF_XGRIDSIDE_Balanced) and gridindex (default to 1) in a non-complete ESMF_Field. The ESMF_Field must not be completed for this to succeed. After this operation, the ESMF_Field contains the ESMF_XGrid internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET or stays ESMF_FIELDSTATUS_GRIDSET.

The arguments are:
field Empty ESMF_Field. After this operation, the ESMF_Field contains the ESMF_XGrid internally but holds no data. The status of the field changes from ESMF_FIELDSTATUS_EMPTY to ESMF_FIELDSTATUS_GRIDSET.

xgrid ESMF_XGrid to be set in the ESMF_Field.

[xgridside] Side of XGrid to retrieve a DistGrid. For valid predefined values see section 33.2.1. The default value is ESMF_XGRIDSIDE_BALANCED.

[gridindex] Index to specify which DistGrid when on side A or side B. The default value is 1.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.43 ESMF_FieldGather - Gather a Fortran array from an ESMF_Field

INTERFACE:

subroutine ESMF_FieldGather<rank><type><kind>(field, farray, & rootPet, tile, vm, rc)

ARGUMENTS:

type(ESMF_Field), intent(in) :: field
<type>(ESMF_KIND_<kind>), intent(out), target :: farray(<rank>)
integer, intent(in) :: rootPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: tile
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gather the data of an ESMF_Field object into the farray located on rootPET. A single DistGrid tile of array must be gathered into farray. The optional tile argument allows selection of the tile. For Fields defined on a single tile DistGrid the default selection (tile 1) will be correct. The shape of farray must match the shape of the tile in Field.

If the Field contains replicating DistGrid dimensions data will be gathered from the numerically higher DEs. Replicated data elements in numerically lower DEs will be ignored.

The implementation of Scatter and Gather is not sequence index based. If the Field is built on arbitrarily distributed Grid, Mesh, LocStream or XGrid, Gather will not gather data to rootPet from source data points corresponding to the sequence index on rootPet. Instead Gather will gather a contiguous memory range from source PET to rootPet.

363
The size of the memory range is equal to the number of data elements on the source PET. Vice versa for the Scatter operation. In this case, the user should use ESMF_FieldRedist to achieve the same data operation result. For examples how to use ESMF_FieldRedist to perform Gather and Scatter, please refer to \[25.3.31\] and \[25.3.30\]

This version of the interface implements the PET-based blocking paradigm: Each PET of the VM must issue this call exactly once for all of its DEs. The call will block until all PET-local data objects are accessible.

For examples and associated documentations using this method see Section \[25.3.27\]

The arguments are:

**field**  The ESMF_Field object from which data will be gathered.

{farray}  The Fortran array into which to gather data. Only root must provide a valid farray, the other PETs may treat farray as an optional argument.

**rootPet**  PET that holds the valid destination array, i.e. farray.

**tile**  The DistGrid tile in field from which to gather farray. By default farray will be gathered from tile 1.

**vm**  Optional ESMF_VM object of the current context. Providing the VM of the current context will lower the method’s overhead.

**rc**  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.44 ESMF_FieldGet - Get object-wide Field information

**INTERFACE:**

```fortran
! Private name; call using ESMF_FieldGet()
subroutine ESMF_FieldGetDefault(field, arrayspec, &
  status, geomtype, grid, mesh, locstream, xgrid, array, &
  typekind, dimCount, rank, staggerloc, meshloc, xgridside, &
  gridindex, gridToFieldMap, ungriddedLBound, ungriddedUBound, &
  totalLWidth, totalUWidth, localDeCount, name, vm, rc)
```

**ARGUMENTS:**

- type(ESMF_Field), intent(in) :: field
- type(ESMF_ArraySpec), intent(out), optional :: arrayspec
- type(ESMF_FieldStatus_Flag), intent(out), optional :: status
- type(ESMF_GeomType_Flag), intent(out), optional :: geomtype
- type(ESMF_Grid), intent(out), optional :: grid
- type(ESMF_Mesh), intent(out), optional :: mesh
- type(ESMF_LocStream), intent(out), optional :: locstream
- type(ESMF_XGrid), intent(out), optional :: xgrid
- type(ESMF_Array), intent(out), optional :: array
- type(ESMF_TypeKind_Flag), intent(out), optional :: typekind
- integer, intent(out), optional :: dimCount
- integer, intent(out), optional :: rank
- type(ESMF_StaggerLoc), intent(out), optional :: staggerloc
- type(ESMF_MeshLoc), intent(out), optional :: meshloc
- type(ESMF_XGridSide_Flag), intent(out), optional :: xgridside
integer, intent(out), optional :: gridindex
integer, intent(out), optional :: gridToFieldMap(:)
integer, intent(out), optional :: ungriddedLBound(:)
integer, intent(out), optional :: ungriddedUBound(:)
integer, intent(out), optional :: totalLWidth(:,:,)
integer, intent(out), optional :: totalUWidth(:,:,)
integer, intent(out), optional :: localDeCount
character(len=*), intent(out), optional :: name
type(ESMF_VM), intent(out), optional :: vm
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r - except those arguments indicated below.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

6.3.0r Added argument vm in order to offer information about the VM on which the Field was created.

DESCRIPTION:

Query an ESMF_Field for various things. All arguments after the field are optional. To select individual items use the named_argument=value syntax. For an example and associated documentation using this method see section 25.3.3.

The arguments are:

field ESMF_Field object to query.

[arrayspec] ESMF_ArraySpec object containing the type/kind/rank information of the Field object.

[status] The status of the Field. See section 25.2.1 for a complete list of values.

[geomtype] The type of geometry on which the Field is built. See section 30.20 for the range of values.

[grid] ESMF_Grid.

[mesh] STATUS:This argument is excluded from the backward compatibility statement.

ESMF_Mesh.

[locstream] STATUS:This argument is excluded from the backward compatibility statement.

ESMF_LocStream.

[xgrid] STATUS:This argument is excluded from the backward compatibility statement.

ESMF_XGrid.

[array] ESMF_Array.

[typekind] TypeKind specifier for Field. See section 50.22 for a complete list of values.

[dimCount] Number of geometrical dimensions in field. For an detailed discussion of this parameter, please see section 25.3.22 and section 25.3.23.
[rank] Number of dimensions in the physical memory of the field data. It is identical to dimCount when the corresponding grid is a non-arbitrary grid. It is less than dimCount when the grid is arbitrarily distributed. For an detailed discussion of this parameter, please see section 25.3.22 and section 25.3.23.

[staggerloc] Stagger location of data in grid cells. For valid predefined values and interpretation of results see section 30.2.6.

[meshloc] STATUS: This argument is excluded from the backward compatibility statement.

The part of the mesh to build the Field on. Can be either ESMF_MESHLOC_NODE or ESMF_MESHLOC_ELEMENT. If not set, defaults to ESMF_MESHLOC_NODE.

[xgridside] STATUS: This argument is excluded from the backward compatibility statement.

The side of the XGrid that the Field was created on. See section 33.2.1 for a complete list of values.

[gridIndex] STATUS: This argument is excluded from the backward compatibility statement.

If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid/Mesh on that side the Field was created on.

[gridToFieldMap] List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

[totalLWidth] Lower bound of halo region. The size of the first dimension of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ). The size of the 2nd dimension of this array is localDeCount.

[totalUWidth] Upper bound of halo region. The size of the first dimension of this array is the number of gridded dimensions in the field. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should max( totalLWidth + totalUWidth + computationalCount, exclusiveCount ). The size of the 2nd dimension of this array is localDeCount.

[localDeCount] Upon return this holds the number of PET-local DEs defined in the DELayout associated with the Field object.

[name] Name of queried item.

[vm] The VM on which the Field object was created.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
25.6.45  ESMF_FieldGet - Get a DE-local Fortran array pointer from a Field

INTERFACE:

! Private name; call using ESMF_FieldGet()
subroutine ESMF_FieldGetDataPtr<rank><type><kind>(field, localDe, &
farrayPtr, exclusiveLBound, exclusiveUBound, exclusiveCount, &
computationalLBound, computationalUBound, computationalCount, &
totalLBound, totalUBound, totalCount, rc)

ARGUMENTS:

type(ESMF_Field), intent(in) :: field
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: localDe
$type (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
integer, intent(out), optional :: exclusiveLBound(:)
integer, intent(out), optional :: exclusiveUBound(:)
integer, intent(out), optional :: exclusiveCount(:)
integer, intent(out), optional :: computationalLBound(:)
integer, intent(out), optional :: computationalUBound(:)
integer, intent(out), optional :: computationalCount(:)
integer, intent(out), optional :: totalLBound(:)
integer, intent(out), optional :: totalUBound(:)
integer, intent(out), optional :: totalCount(:)
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get a Fortran pointer to DE-local memory allocation within field. For convenience DE-local bounds can be queried at the same time. For an example and associated documentation using this method see section 25.3.2.

The arguments are:

field  ESMF_Field object.

[localDe]  Local DE for which information is requested. [0,..,localDeCount-1]. For localDeCount=1 the localDe argument may be omitted, in which case it will default to localDe=0.

farrayPtr  Fortran array pointer which will be pointed at DE-local memory allocation. It depends on the specific entry point of ESMF_FieldCreate() used during field creation, which Fortran operations are supported on the returned farrayPtr. See 25.4 for more details.

[exclusiveLBound]  Upon return this holds the lower bounds of the exclusive region. exclusiveLBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.
Upon return this holds the upper bounds of the exclusive region. exclusiveUBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items, exclusiveUBound-exclusiveLBound+1, in the exclusive region per dimension. exclusiveCount must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the computational region. computationalLBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the computational region. computationalUBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the computational region per dimension (i.e. computationalUBound-computationalLBound+1). computationalCount must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the total region. totalLBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the total region. totalUBound must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the total region per dimension (i.e. totalUBound-totalLBound+1). totalCount must be allocated to be of size equal to field's dimCount. See section 27.2.6 for a description of the regions and their associated bounds and counts.

Return code; equals ESMF_SUCCESS if there are no errors.

25.6.46 ESMF_FieldGetBounds - Get DE-local Field data bounds

INTERFACE:

! Private name; call using ESMF_FieldGetBounds() subroutine ESMF_FieldGetBounds(field, localDe, & exclusiveLBound, exclusiveUBound, exclusiveCount, computationalLBound, & computationalUBound, computationalCount, totalLBound, & totalUBound, totalCount, rc)

ARGUMENTS:

type(ESMF_Field), intent(in) :: field
-- The following arguments require argument keyword syntax (e.g. rc=rc). -- integer, intent(in), optional :: localDe
integer, intent(out), optional :: exclusiveLBound()
integer, intent(out), optional :: exclusiveUBound(:)
integer, intent(out), optional :: exclusiveCount(:)
integer, intent(out), optional :: computationalLBound(:)
integer, intent(out), optional :: computationalUBound(:)
integer, intent(out), optional :: computationalCount(:)
integer, intent(out), optional :: totalLBound(:)
integer, intent(out), optional :: totalUBound(:)
integer, intent(out), optional :: totalCount(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method returns the bounds information of a field that consists of an internal grid and an internal array. The exclusive and computational bounds are shared between the grid and the array but the total bounds are the array bounds plus the halo width. The count is the number of elements between each bound pair.

The arguments are:

field Field to get the information from.

[localDe] Local DE for which information is requested. [0,..,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.

exclusiveLBound] Upon return this holds the lower bounds of the exclusive region. exclusiveLBound must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

exclusiveUBound] Upon return this holds the upper bounds of the exclusive region. exclusiveUBound must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

exclusiveCount] Upon return this holds the number of items, exclusiveUBound-exclusiveLBound+1, in the exclusive region per dimension. exclusiveCount must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

computationalLBound] Upon return this holds the lower bounds of the stagger region. computationalLBound must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

computationalUBound] Upon return this holds the upper bounds of the stagger region. computationalUBound must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

computationalCount] Upon return this holds the number of items in the computational region per dimension (i.e. computationalUBound-computationalLBound+1). computationalCount must be allocated to be of size equal to the field rank. Please see section 30.3.16 for a description of the regions and their associated bounds and counts.

totalLBound] Upon return this holds the lower bounds of the total region. totalLBound must be allocated to be of size equal to the field rank.

totalUBound] Upon return this holds the upper bounds of the total region. totalUBound must be allocated to be of size equal to the field rank.
Upon return this holds the number of items in the total region per dimension (i.e. \(\text{totalUBound}-\text{totalLBound}+1\)). \[\text{totalCount}\] must be allocated to be of size equal to the field rank.

\[\text{rc}\] Return code: equals \text{ESMF_SUCCESS} if there are no errors.

### 25.6.47 ESMF_FieldHalo - Execute a FieldHalo operation

**INTERFACE:**

```fortran
subroutine ESMF_FieldHalo(field, routehandle, &
  routesyncflag, finishedflag, checkflag, rc)
```

**ARGUMENTS:**

- `type(ESMF_Field), intent(inout) :: field`
- `type(ESMF_RouteHandle), intent(inout) :: routehandle`
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --`
- `type(ESMF_RouteSync_Flag), intent(in), optional :: routesyncflag`
- `logical, intent(out), optional :: finishedflag`
- `logical, intent(in), optional :: checkflag`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Execute a precomputed Field halo operation for \(\text{field}\). The \(\text{field}\) argument must be weakly congruent and type-kind conform to the Field used during \text{ESMF_FieldHaloStore()}\). Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same \(\text{routehandle}\) can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions.

See \text{ESMF_FieldHaloStore()}\) on how to precompute \(\text{routehandle}\).

This call is \text{collective} across the current VM.

- `\text{field} \text{ESMF_Field} containing data to be haloed.`
- `\text{routehandle} \text{Handle to the precomputed Route.}`
- `[\text{routesyncflag}]` Indicate communication option. Default is \text{ESMF_ROUTESYNC_BLOCKING}, resulting in a blocking operation. See section \ref{50.44} for a complete list of valid settings.
- `[\text{finishedflag}]` Used in combination with \text{routesyncflag} = \text{ESMF_ROUTESYNC_NBTESTFINISH}. Returned \text{finishedflag} equal to .true. indicates that all operations have finished. A value of .false. indicates that there are still unfinished operations that require additional calls with \text{routesyncflag} = \text{ESMF_ROUTESYNC_NBTESTFINISH}, or a final call with \text{routesyncflag} = \text{ESMF_ROUTESYNC_NBWAITFINISH}. For all other \text{routesyncflag} settings the returned value in \text{finishedflag} is always .true. .
[checkflag] If set to .TRUE. the input Field pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.48 ESMF_FieldHaloRelease - Release resources associated with a Field halo operation

INTERFACE:

subroutine ESMF_FieldHaloRelease(routehandle, rc)

ARGUMENTS:

type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resouces associated with a Field halo operation. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.49 ESMF_FieldHaloStore - Store a FieldHalo operation

INTERFACE:

subroutine ESMF_FieldHaloStore(field, routehandle, &
startregion, haloLDepth, haloUDepth, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field

type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_StartRegion_Flag), intent(in), optional :: startregion
integer, intent(in), optional :: haloLDepth(:)
integer, intent(in), optional :: haloUDepth(:)
integer, intent(out), optional :: rc

371
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store a Field halo operation over the data in field. By default, i.e. without specifying startregion, haloLDepth and haloUDepth, all elements in the total Field region that lie outside the exclusive region will be considered potential destination elements for halo. However, only those elements that have a corresponding halo source element, i.e. an exclusive element on one of the DEs, will be updated under the halo operation. Elements that have no associated source remain unchanged under halo.

Specifying startregion allows to change the shape of the effective halo region from the inside. Setting this flag to ESMF_STARTREGION_COMPUTATIONAL means that only elements outside the computational region of the Field are considered for potential destination elements for halo. The default is ESMF_STARTREGION_EXCLUSIVE.

The haloLDepth and haloUDepth arguments allow to reduce the extent of the effective halo region. Starting at the region specified by startregion, the haloLDepth and haloUDepth define a halo depth in each direction. Note that the maximum halo region is limited by the total Field region, independent of the actual haloLDepth and haloUDepth setting. The total Field region is local DE specific. The haloLDepth and haloUDepth are interpreted as the maximum desired extent, reducing the potentially larger region available for halo.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldHalo() on any Field that is weakly congruent and typekind conform to field. Congruent Fields possess matching DistGrids, and the shape of the local field tiles matches between the Fieldss for every DE. For weakly congruent Fieldss the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fieldss that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

field ESMF_Field containing data to be haloed. The data in this Field may be destroyed by this call.
routehandle Handle to the precomputed Route.
[startregion] The start of the effective halo region on every DE. The default setting is ESMF_STARTREGION_EXCLUSIVE, rendering all non-exclusive elements potential halo destination elements. See section 50.47 for a complete list of valid settings.
[haloLDepth] This vector specifies the lower corner of the effective halo region with respect to the lower corner of startregion. The size of haloLDepth must equal the number of distributed Array dimensions.
[haloUDepth] This vector specifies the upper corner of the effective halo region with respect to the upper corner of startregion. The size of haloUDepth must equal the number of distributed Array dimensions.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.50 ESMF_FieldPrint - Print Field information

INTERFACE:

subroutine ESMF_FieldPrint(field, rc)
ARGUMENTS:

```fortran
  type(ESMF_Field), intent(in) :: field
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Prints information about the `field` to `stdout`. This subroutine goes through the internal data members of a field data type and prints information of each data member.

The arguments are:

- **field**  An `ESMF_Field` object.
- **[rc]**  Return code; equals `ESMF_SUCCESS` if there are no errors.

25.6.51  ESMF_FieldRead - Read Field data from a file

INTERFACE:

```fortran
subroutine ESMF_FieldRead(field, file, &
  variableName, timeslice, iofmt, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_Field), intent(inout) :: field
  character(*) , intent(in) :: file
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  character(*) , intent(in), optional :: variableName
  integer, intent(in), optional :: timeslice
  type(ESMF_IOFmt_Flag), intent(in), optional :: iofmt
  integer, intent(out), optional :: rc
```

DESCRIPTION:

Read Field data from a file and put it into an `ESMF_Field` object. For this API to be functional, the environment variable `ESMF_PIO` should be set to "internal" when the ESMF library is built. Please see the section on Data I/O, 36.3

Limitations:

- Only 1 DE per PET supported.
• Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

field The ESMF_Field object in which the read data is returned.
file The name of the file from which Field data is read.
[variableName] Variable name in the file; default is the "name" of Field. Use this argument only in the IO format (such as NetCDF) that supports variable name. If the IO format does not support this (such as binary format), ESMF will return an error code.
timeslice Number of slices to be read from file, starting from the 1st slice
[iofmt] The IO format. Please see Section 50.2 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.52 ESMF_FieldRedist - Execute a Field redistribution

INTERFACE:

subroutine ESMF_FieldRedist(srcField, dstField, routehandle, &
checkflag, rc)

ARGUMENTS:

  type(ESMF_Field), intent(in),optional :: srcField
  type(ESMF_Field), intent(inout),optional :: dstField
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical, intent(in), optional :: checkflag
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Execute a precomputed Field redistribution from srcField to dstField. Both srcField and dstField must be congruent and typekind conform with the respective Fields used during ESMF_FieldRedistStore(). Congruent Fields possess matching DistGrids and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it’s necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field redist feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.
The srcField and dstField arguments are optional in support of the situation where srcField and/or dstField are not defined on all PETs. The srcField and dstField must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

See ESMF_FieldRedistStore() on how to precompute routehandle.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 25.3.29.

[srcField] ESMF_Field with source data.
[dstField] ESMF_Field with destination data.

routehandle  Handle to the precomputed Route.

[checkflag] If set to .TRUE. the input Field pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

25.6.53  ESMF_FieldRedistRelease - Release resources associated with Field redistribution

INTERFACE:

    subroutine ESMF_FieldRedistRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer,        intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a Field redistribution. After this call routehandle becomes invalid.

routehandle  Handle to the precomputed Route.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
25.6.54 ESMF_FieldRedistStore - Precompute Field redistribution with a local factor argument

INTERFACE:

! Private name; call using ESMF_FieldRedistStore()
subroutine ESMF_FieldRedistStore<type><kind>(srcField, dstField, &
   routehandle, factor, srcToDstTransposeMap, rc)

ARGUMENTS:

   type(ESMF_Field),               intent(in)  :: srcField
   type(ESMF_Field),               intent(inout) :: dstField
   type(ESMF_RouteHandle),        intent(inout) :: routehandle
   <type>(ESMF_KIND_<kind>),       intent(in)   :: factor
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer,                        intent(in), optional :: srcToDstTransposeMap(:)
   integer,                        intent(out), optional :: rc

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface com- piles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

ESMF_FieldRedistStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_FieldRedistStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_FieldRedistStore() method, as provided through the separate entry points shown in 25.6.54 and 25.6.55 is described in the following paragraphs as a whole.

Store a Field redistribution operation from srcField to dstField. Interface 25.6.54 allows PETs to specify a factor argument. PETs not specifying a factor argument call into interface 25.6.55. If multiple PETs specify the factor argument, its type and kind, as well as its value must match across all PETs. If none of the PETs specify a factor argument the default will be a factor of 1. The resulting factor is applied to all of the source data during redistribution, allowing scaling of the data, e.g. for unit transformation.

Both srcField and dstField are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices.

Source Field, destination Field, and the factor may be of different <type><kind>. Further, source and destination Fields may differ in shape, however, the number of elements must match.

If srcToDstTransposeMap is not specified the redistribution corresponds to an identity mapping of the sequentialized source Field to the sequentialized destination Field. If the srcToDstTransposeMap argument is provided it must be identical on all PETs. The srcToDstTransposeMap allows source and destination Field dimensions to be transposed during the redistribution. The number of source and destination Field dimensions must be equal under this condition and the size of mapped dimensions must match.

It is erroneous to specify the identical Field object for srcField and dstField arguments.
The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldRedist() on any pair of Fields that are weakly congruent and typekind conform with the srcField, dstField pair. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it’s necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field redist feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 25.3.29.

The arguments are:

**srcField** ESMF_Field with source data.

**dstField** ESMF_Field with destination data. The data in this Field may be destroyed by this call.

**routehandle** Handle to the precomputed Route.

**factor** Factor by which to multiply data. Default is 1. See full method description above for details on the interplay with other PETs.

**[srcToDstTransposeMap]** List with as many entries as there are dimensions in srcField. Each entry maps the corresponding srcField dimension against the specified dstField dimension. Mixing of distributed and undistributed dimensions is supported.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.55 ESMF_FieldRedistStore - Precompute Field redistribution without a local factor argument

**INTERFACE:**

```fortran
! Private name; call using ESMF_FieldRedistStore()
subroutine ESMF_FieldRedistStoreNF(srcField, dstField, &
routehandle, srcToDstTransposeMap, rc)
ARGUMENTS:

  type(ESMF_Field), intent(in) :: srcField
  type(ESMF_Field), intent(inout) :: dstField
  type(ESMF_RouteHandle), intent(inout) :: routehandle

  -- The following arguments require argument keyword syntax (e.g. rc=rc).
  integer, intent(in), optional :: srcToDstTransposeMap
  integer, intent(out), optional :: rc
```

---

377
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

ESMF_FieldRedistStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_FieldRedistStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_FieldRedistStore() method, as provided through the separate entry points shown in 25.6.54 and 25.6.55 is described in the following paragraphs as a whole.

Store a Field redistribution operation from srcField to dstField. Interface 25.6.54 allows PETs to specify a factor argument. PETs not specifying a factor argument call into interface 25.6.55. If multiple PETs specify the factor argument, its type and kind, as well as its value must match across all PETs. If none of the PETs specify a factor argument the default will be a factor of 1. The resulting factor is applied to all of the source data during redistribution, allowing scaling of the data, e.g. for unit transformation.

Both srcField and dstField are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices.

Source Field, destination Field, and the factor may be of different <type><kind>. Further, source and destination Fields may differ in shape, however, the number of elements must match.

If srcToDstTransposeMap is not specified the redistribution corresponds to an identity mapping of the sequentialized source Field to the sequentialized destination Field. If the srcToDstTransposeMap argument is provided it must be identical on all PETs. The srcToDstTransposeMap allows source and destination Field dimensions to be transposed during the redistribution. The number of source and destination Field dimensions must be equal under this condition and the size of mapped dimensions must match.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldRedist() on any pair of Fields that are weakly congruent and typekind conform with the srcField, dstField pair. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it's necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field redist feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 25.3.29.

The arguments are:

srcField  ESMF_Field with source data.

dstField  ESMF_Field with destination data. The data in this Field may be destroyed by this call.

routehandle  Handle to the precomputed Route.

[srcToDstTransposeMap] List with as many entries as there are dimensions in srcField. Each entry maps the corresponding srcField dimension against the specified dstField dimension. Mixing of distributed and undistributed dimensions is supported.
Return code; equals ESMF_SUCCESS if there are no errors.

25.6.56 ESMF_FieldRegrid - Compute a regridding operation

INTERFACE:

```fortran
subroutine ESMF_FieldRegrid(srcField, dstField, &
  routehandle, zeroRegion, &
  termOrderFlag, checkFlag, rc)
```

ARGUMENTS:

```fortran
type(ESMF_Field), intent(in), optional :: srcField
type(ESMF_Field), intent(inout), optional :: dstField
type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Region_Flag), intent(in), optional :: zeroRegion
type(ESMF_TermOrder_Flag), intent(in), optional :: termOrderFlag
logical, intent(in), optional :: checkFlag
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added argument `termOrderFlag`. The new argument gives the user control over the order in which the src terms are summed up.

DESCRIPTION:

Execute the precomputed regrid operation stored in `routehandle` to interpolate from `srcField` to `dstField`. See `ESMF_FieldRegridStore()` on how to precompute the routehandle.

Both `srcField` and `dstField` must be weakly congruent with the respective Fields used during `ESMF_FieldRegridStore()`. Congruent Fields possess matching DistGrids and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. You can apply the routehandle between any set of Fields weakly congruent to the original Fields used to create the routehandle without incurring an error. However, if you want the routehandle to be the same interpolation between the grid objects upon which the Fields are build as was calculated with the original `ESMF_FieldRegridStore()` call, then there are additional constraints on the grid objects. To be the same interpolation, the grid objects upon which the Fields are build must contain the same coordinates at the stagger locations involved in the regridding as the original source and destination Fields used in the...
ESMF_FieldRegridStore() call. The routehandle represents the interpolation between the grid objects as they were during the ESMF_FieldRegridStore() call. So if the coordinates at the stagger location in the grid objects change, a new call to ESMF_FieldRegridStore() is necessary to compute the interpolation between that new set of coordinates.

The srcField and dstField arguments are optional in support of the situation where srcField and/or dstField are not defined on all PETs. The srcField and dstField must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

This call is collective across the current VM.

[srcField] ESMF_Field with source data.

dstField] ESMF_Field with destination data.

routehandle Handle to the precomputed Route.

[zeroregion] If set to ESMF_REGION_TOTAL (default) the total regions of all DEs in dstField will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to ESMF_REGION_EMPTY the elements in dstField will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting zeroregion to ESMF_REGION_SELECT will only zero out those elements in the destination Array that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.

[termorderflag] Specifies the order of the source side terms in all of the destination sums. The termorderflag only affects the order of terms during the execution of the RouteHandle. See the 35.2.1 section for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods. See 50.51 for a full list of options. The default is ESMF_TERMORDER_FREE, allowing maximum flexibility in the order of terms for optimum performance.

[checkflag] If set to .TRUE. the input Array pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.57 ESMF_FieldRegridRelease - Free resources used by a regridding operation

INTERFACE:

    subroutine ESMF_FieldRegridRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Free resources used by regrid objec

The arguments are:

routehandle Handle carrying the sparse matrix

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.58 ESMF_FieldRegridStore - Precompute a Field regridding operation and return a RouteHandle and weights

INTERFACE:

! Private name; call using ESMF_FieldRegridStore()
subroutine ESMF_FieldRegridStoreNX(srcField, dstField, &

integer, intent(out), optional :: rc

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

**5.2.0rp1** Added arguments `factorList` and `factorIndexList`. Started to deprecate arguments `weights` and `indices`. This corrects an inconsistency of this interface with all other ESMF methods that take these same arguments.

**6.1.0** Added arguments `ignoreDegenerate`, `srcTermProcessing`, `pipelineDepth`, and `unmappedDstList`. The argument `ignoreDegenerate` allows the user to skip degenerate cells in the regridding instead of stopping with an error. The two arguments `srcTermProcessing` and `pipelineDepth` provide access to the tuning parameters affecting the sparse matrix execution. The argument `unmappedDstList` allows the user to get a list of the destination items which the regridding couldn’t map to a source.

**6.3.0r** Added argument `lineType`. This argument allows the user to control the path of the line between two points on a sphere surface. This allows the user to use their preferred line path for the calculation of distances and the shape of cells during regrid weight calculation on a sphere.

**DESCRIPTION:**

Creates a sparse matrix operation (stored in `routehandle`) that contains the calculations and communications necessary to interpolate from `srcField` to `dstField`. The routehandle can then be used in the call `ESMF_FieldRegrid()` to interpolate between the Fields. The user may also get the interpolation matrix in sparse matrix form via the optional arguments `factorList` and `factorIndexList`.

The routehandle generated by this call is based just on the coordinates in the Grids or Meshes contained in the Fields. If those coordinates don’t change the routehandle can be used repeatedly to interpolate from the source Field to the destination Field. This is true even if the data in the Fields changes. The routehandle may also be used to interpolate between any source and destination Field which are created on the same location in the same Grid or Mesh as the original Fields.

When it’s no longer needed the routehandle should be destroyed by using `ESMF_FieldRegridRelease()` to free the memory it’s using.

The arguments are:

**srcField** Source Field.

**dstField** Destination Field. The data in this Field may be overwritten by this call.

**[srcMaskValues]** Mask information can be set in the Grid (see §30.3.14) or Mesh (see §32.3.8) upon which the `srcField` is built. The `srcMaskValues` argument specifies the values in that mask information which indicate a source point should be masked out. In other words, a location is masked if and only if the value for that
location in the mask information matches one of the values listed in srcMaskValues. If srcMaskValues is not specified, no masking will occur.

[dstMaskValues] Mask information can be set in the Grid (see §30.3.14) or Mesh (see §32.3.8) upon which the dstField is built. The dstMaskValues argument specifies the values in that mask information which indicate a destination point should be masked out. In other words, a location is masked if and only if the value for that location in the mask information matches one of the values listed in dstMaskValues. If dstMaskValues is not specified, no masking will occur.

[regridmethod] The type of interpolation. Please see Section §50.43.1 for a list of valid options. If not specified, defaults to ESMF_REGRIDMETHOD_BILINEAR.

[polemethod] Which type of artificial pole to construct on the source Grid for regridding. Please see Section §50.41.1 for a list of valid options. If not specified, defaults to ESMF_POLEMETHOD_ALLAVG.

[regridPoleNPnts] If polemethod is ESMF_POLEMETHOD_NPNTAVG. This parameter indicates how many points should be averaged over. Must be specified if polemethod is ESMF_POLEMETHOD_NPNTAVG.

[lineType] This argument controls the path of the line which connects two points on a sphere surface. This in turn controls the path along which distances are calculated and the shape of the edges that make up a cell. Both of these quantities can influence how interpolation weights are calculated. As would be expected, this argument is only applicable when srcField and dstField are built on grids which lie on the surface of a sphere. Section §50.32 shows a list of valid options for this argument. If not specified, the default depends on the regrid method. Section §50.32 has the defaults by line type. Figure 23.2.8 shows which line types are supported for each regrid method as well as showing the default line type by regrid method.

[unmappedaction] Specifies what should happen if there are destination points that can’t be mapped to a source cell. Options are ESMF_UNMAPPEDACTION_ERROR or ESMF_UNMAPPEDACTION_IGNORE. If not specified, defaults to ESMF_UNMAPPEDACTION_ERROR. The unmapped destination point error detection currently doesn’t work with the ESMF_REGRIDMETHOD_NEAREST DTOS regrid method, so with that regrid method this subroutine will behave as if ESMF_UNMAPPEDACTION_IGNORE is always on.

[ignoreDegenerate] Ignore degenerate cells when checking the input Grids or Meshes for errors. If this is set to .true., then the regridding proceeds, but degenerate cells will be skipped. If set to false, a degenerate cell produces an error. This currently only applies to the ESMF_REGRIDMETHOD_CONSERVE method, other regrid methods currently always skip degenerate cells.

[srcTermProcessing] The srcTermProcessing parameter controls how many source terms, located on the same PET and summing into the same destination element, are summed into partial sums on the source PET before being transferred to the destination PET. A value of 0 indicates that the entire arithmetic is done on the destination PET; source elements are neither multiplied by their factors nor added into partial sums before being sent off by the source PET. A value of 1 indicates that source elements are multiplied by their factors on the source side before being sent to the destination PET. Larger values of srcTermProcessing indicate the maximum number of terms in the partial sums on the source side.

Note that partial sums may lead to bit-for-bit differences in the results. See section §57.2.1 for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods.

The ESMF_FieldRegridStore() method implements an auto-tuning scheme for the srcTermProcessing parameter. The intent on the srcTermProcessing argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used for the srcTermProcessing parameter, and the auto-tuning phase is skipped. In this case the srcTermProcessing argument is not modified on return. If the provided argument is < 0, the srcTermProcessing parameter is determined internally using the auto-tuning scheme. In this case the srcTermProcessing argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional srcTermProcessing argument is omitted.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstanding during a sparse matrix exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.
Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

The ESMF_FieldRegridStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified on return. If the provided argument is \(< 0\), the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

**routehandle** The communication handle that implements the regrid operation and that can be used later in the ESMF_FieldRegrid() call. The routehandle is optional so that if the user doesn’t need it, then they can indicate that by not requesting it. The time to compute the routehandle can be a significant fraction of the time taken by this method, so if it’s not needed then not requesting it is worthwhile.

**factorList** The list of coefficients for a sparse matrix which interpolates from srcField to dstField. The array coming out of this variable is in the appropriate format to be used in other ESMF sparse matrix multiply calls, for example ESMF_FieldSMMStore(). The factorList array is allocated by the method and the user is responsible for deallocating it.

**factorIndexList** The indices for a sparse matrix which interpolates from srcField to dstField. This argument is a 2D array containing pairs of source and destination sequence indices corresponding to the coefficients in the factorList argument. The first dimension of factorIndexList is of size 2. factorIndexList(1,:) specifies the sequence index of the source element in the srcField. factorIndexList(2,:) specifies the sequence index of the destination element in the dstField. The second dimension of factorIndexList steps through the list of pairs, i.e. size(factorIndexList,2)==size(factorList). The array coming out of this variable is in the appropriate format to be used in other ESMF sparse matrix multiply calls, for example ESMF_FieldSMMStore(). The factorIndexList array is allocated by the method and the user is responsible for deallocating it.

**weights** DEPRECATED ARGUMENT! Please use the argument factorList instead.

**indices** DEPRECATED ARGUMENT! Please use the argument factorIndexList instead.

**srcFracField** The fraction of each source cell participating in the regridding. Only valid when regridmethod is ESMF_REGRIDMETHOD_CONSERVE. This Field needs to be created on the same location (e.g. staggerloc) as the srcField.

**dstFracField** The fraction of each destination cell participating in the regridding. Only valid when regridmethod is ESMF_REGRIDMETHOD_CONSERVE. This Field needs to be created on the same location (e.g. staggerloc) as the dstField. It is important to note that the current implementation of conservative regridding doesn’t normalize the interpolation weights by the destination fraction. This means that for a destination grid which only partially overlaps the source grid the destination field which is output from the regrid operation should be divided by the corresponding destination fraction to yield the true interpolated values for cells which are only partially covered by the source grid.

**unmappedDstList** The list of the sequence indices for locations in dstField which couldn’t be mapped the srcField. The list on each PET only contains the unmapped locations for the piece of the dstField on that PET. If a destination point is masked, it won’t be put in this list. This option currently doesn’t work with the ESMF_REGRIDMETHOD_NEAREST_DTOS regrid method.

**rc** Return code; equals ESMF_SUCCESS if there are no errors.
25.6.59  ESMF_FieldRegridStore - Precompute a Field regridding operation and return a RouteHandle using XGrid

INTERFACE:

! Private name; call using ESMF_FieldRegridStore()
subroutine ESMF_FieldRegridStoreX(xgrid, srcField, dstField, &
    routehandle, srcFracField, dstFracField, &
    srcMergeFracField, dstMergeFracField, rc)

ARGUMENTS:

    type(ESMF_XGrid), intent(in) :: xgrid
    type(ESMF_Field), intent(in) :: srcField
    type(ESMF_Field), intent(inout) :: dstField
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_RouteHandle), intent(inout), optional :: routehandle
    type(ESMF_Field), intent(inout), optional :: srcFracField
    type(ESMF_Field), intent(inout), optional :: dstFracField
    type(ESMF_Field), intent(inout), optional :: srcMergeFracField
    type(ESMF_Field), intent(inout), optional :: dstMergeFracField
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.3.0 Added arguments srcFracField, dstFracField, srcMergeFracField, and dstMergeFracField. These fraction Fields allow a user to calculate correct flux regridded through ESMF_XGrid.

DESCRIPTION:

Creates a sparse matrix operation (stored in routehandle) that contains the calculations and communications necessary to interpolate from srcField to dstField. The routehandle can then be used in the call ESMF_FieldRegrid() to interpolate between the ESMF_Fields. Information such as index mapping and weights are obtained from the XGrid by matching the Field Grids or Meshes in the XGrid. It’s erroneous to have matching Grid or Mesh objects in the srcField and dstField. They must be different in either topological or geometric characteristics. For ESMF_Fields built on identical ESMF_Grid or ESMF_Mesh on different VM, user can use ESMF_FieldRedistStore() and ESMF_FieldRedist() methods to communicate data across different VM.

The routehandle generated by this call is subsequently computed based on these information. If those information don’t change the routehandle can be used repeatedly to interpolate from the source Field to the destination Field. This is true even if the data in the Fields changes. The routehandle may also be used to interpolate between any source and
destination Field which are created on the same stagger location and Grid or on the same mesh location and Mesh as the original Fields.

When it’s no longer needed the routehandle should be destroyed by using ESMF_FieldRegridRelease() to free the memory it’s using. Note ESMF(Field)RegridStore() assumes the coordinates used in the Grids upon which the Fields are built are in degrees.

The arguments are:

**xgrid**  Exchange Grid.

**srcField**  Source Field.

**dstField**  Destination Field. The data in this Field may be overwritten by this call.

[routetehandle]  The handle that implements the regrid and that can be used in later ESMF_FieldRegrid.

[srcFracField]  The fraction of each source cell participating in the regridding returned from this call. This Field needs to be created on the same Grid and location (e.g staggerloc) as the srcField.

[dstFracField]  The fraction of each destination cell participating in the regridding returned from this call. This Field needs to be created on the same Grid and location (e.g staggerloc) as the dstField.

[srcMergeFracField]  The fraction of each source cell as a result of Grid merge returned from this call. This Field needs to be created on the same Grid and location (e.g staggerloc) as the srcField.

[dstMergeFracField]  The fraction of each destination cell as a result of Grid merge returned from this call. This Field needs to be created on the same Grid and location (e.g staggerloc) as the dstField.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

---

25.6.60  ESMF_FieldRegridGetArea - Get the area of the cells used for conservative interpolation

**INTERFACE:**

```fortran
subroutine ESMF_FieldRegridGetArea(areaField, rc)
```

**RETURN VALUE:**

**ARGUMENTS:**

```fortran
type(ESMF_Field), intent(inout) :: areaField
integer, intent(out), optional :: rc
```

**DESCRIPTION:**

This subroutine gets the area of the cells used for conservative interpolation for the grid object associated with areaField and puts them into areaField. If created on a 2D Grid, it must be built on the ESMF_STAGGERLOC_CENTER stagger location. If created on a 3D Grid, it must be built on the
ESMF_STAGGERLOC_CENTER_VCENTER stagger location. If created on a Mesh, it must be built on the ESMF_MESHLOC_ELEMENT mesh location.

The arguments are:

areaField  The Field to put the area values in.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

25.6.61  ESMF_FieldScatter - Scatter a Fortran array across the ESMF_Field

INTERFACE:

subroutine ESMF_FieldScatter<rank><type><kind>(field, farray, & rootPet, tile, vm, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
mtype (ESMF_KIND_mtypekind),intent(in), target :: farra y(mdim)
integer, intent(in) :: rootPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: tile
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Scatter the data of farray located on rootPET across an ESMF_Field object. A single farray must be scattered across a single DistGrid tile in Field. The optional tile argument allows selection of the tile. For Fields defined on a single tile DistGrid the default selection (tile 1) will be correct. The shape of farray must match the shape of the tile in Field.

If the Field contains replicating DistGrid dimensions data will be scattered across all of the replicated pieces.

The implementation of Scatter and Gather is not sequence index based. If the Field is built on arbitrarily distributed Grid, Mesh, LocStream or XGrid, Scatter will not scatter data from rootPet to the destination data points corresponding to the sequence index on the rootPet. Instead Scatter will scatter a contiguous memory range from rootPet to destination PET. The size of the memory range is equal to the number of data elements on the destination PET. Vice versa for the Gather operation. In this case, the user should use ESMF_FieldRedist to achieve the same data operation result. For examples how to use ESMF_FieldRedist to perform Gather and Scatter, please refer to 25.3.31 and 25.3.30.

This version of the interface implements the PET-based blocking paradigm: Each PET of the VM must issue this call exactly once for all of its DEs. The call will block until all PET-local data objects are accessible.
For examples and associated documentations using this method see Section 25.3.28.

The arguments are:

**field** The ESMF_Field object across which data will be scattered.

**{farray}** The Fortran array that is to be scattered. Only root must provide a valid farray, the other PETs may treat farray as an optional argument.

**rootPet** PET that holds the valid data in farray.

**[tile]** The DistGrid tile in field into which to scatter farray. By default farray will be scattered into tile 1.

**[vm]** Optional ESMF_VM object of the current context. Providing the VM of the current context will lower the method’s overhead.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

### 25.6.62 ESMF_FieldSMM - Execute a Field sparse matrix multiplication

**INTERFACE:**

```fortran
subroutine ESMF_FieldSMM(srcField, dstField, routehandle, &
zeroregion, termorderflag, checkflag, rc)
```

**ARGUMENTS:**

- type(ESMF_Field), intent(in), optional :: srcField
- type(ESMF_Field), intent(inout), optional :: dstField
- type(ESMF_RouteHandle), intent(inout) :: routehandle

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

6.1.0 Added argument termorderflag. The new argument gives the user control over the order in which the src terms are summed up.

**DESCRIPTION:**

Execute a precomputed Field sparse matrix multiplication from srcField to dstField. Both srcField and dstField must be congruent and typekind conform with the respective Fields used during ESMF_FieldSMMStore(). Congruent Fields possess matching DistGrids and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most
undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it’s necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field SMM feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.

The srcField and dstField arguments are optional in support of the situation where srcField and/or dstField are not defined on all PETs. The srcField and dstField must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

See ESMF_FieldSMMStore() on how to precompute routehandle.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 25.3.32.

[srcField] ESMF_Field with source data.

[dstField] ESMF_Field with destination data.

routehandle Handle to the precomputed Route.

[zeroregion] If set to ESMF_REGION_TOTAL (default) the total regions of all DEs in dstField will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to ESMF_REGION_EMPTY the elements in dstField will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting zeroregion to ESMF_REGION_SELECT will only zero out those elements in the destination Field that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.

[termorderflag] Specifies the order of the source side terms in all of the destination sums. The termorderflag only affects the order of terms during the execution of the RouteHandle. See the 35.2.1 section for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods. See 50.51 for a full list of options. The default is ESMF_TERMORDER_FREE, allowing maximum flexibility in the order of terms for optimum performance.

[checkflag] If set to .TRUE. the input Field pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.63 ESMF_FieldSMMRelease - Release resources associated with Field

sparse matrix multiplication

INTERFACE:

    subroutine ESMF_FieldSMMRelease(routehandle, rc)

ARGUMENTS:
type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with a Field sparse matrix multiplication. After this call routehandle becomes invalid.

**routehandle** Handle to the precomputed Route.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 25.6.64 ESMF_FieldSMMStore - Precompute Field sparse matrix multiplication with local factors

INTERFACE:

```fortran
! Private name; call using ESMF_FieldSMMStore()
subroutine ESMF_FieldSMMStore<type><kind>(srcField, dstField, &
  routehandle, factorList, factorIndexList, &
  srcTermProcessing, pipelineDepth, rc)
```

ARGUMENTS:

```fortran
type(ESMF_Field), intent(in) :: srcField
type(ESMF_Field), intent(inout) :: dstField
type(ESMF_RouteHandle), intent(inout) :: routehandle
(type<ESMF_KIND_<kind>), intent(in) :: factorList(:)
integer, intent(in), :: factorIndexList(:,:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(inout), optional :: srcTermProcessing
integer, intent(inout), optional :: pipelineDepth
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:
6.1.0 Added arguments srcTermProcessing, pipelineDepth. The two arguments srcTermProcessing and pipelineDepth provide access to the tuning parameters affecting the sparse matrix execution.

DESCRIPTION:

Store a Field sparse matrix multiplication operation from srcField to dstField. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

Both srcField and dstField are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices. SMM corresponds to an identity mapping of the source Field vector to the destination Field vector.

Source and destination Fields may be of different <type><kind>. Further source and destination Fields may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_FieldSMM() on any pair of Fields that are weakly congruent and typekind conform with the srcField, dstField pair. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the leftmost undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it’s necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field SMM feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.

This method is overloaded for:

ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

For examples and associated documentations using this method see Section 25.3.32.

The arguments are:

srcField ESMF_Field with source data.
dstField ESMF_Field with destination data. The data in this Field may be destroyed by this call.
routenlist Handle to the precomputed Route.
factorList List of non-zero coefficients.
factorIndexList Pairs of sequence indices for the factors stored in factorList.

The second dimension of factorIndexList steps through the list of pairs, i.e. size(factorIndexList,2) == size(factorList). The first dimension of factorIndexList is either of size 2 or size 4.

The second dimension of factorIndexList steps through the list of
In the *size 2 format* factorIndexList(1,:) specifies the sequence index of the source element in the srcField while factorIndexList(2,:) specifies the sequence index of the destination element in dstField. For this format to be a valid option source and destination Fields must have matching number of tensor elements (the product of the sizes of all Field tensor dimensions). Under this condition an identity matrix can be applied within the space of tensor elements for each sparse matrix factor.

The *size 4 format* is more general and does not require a matching tensor element count. Here the factorIndexList(1,:) specifies the sequence index while factorIndexList(2,:) specifies the tensor sequence index of the source element in the srcField. Further factorIndexList(3,:) specifies the sequence index and factorIndexList(4,:) specifies the tensor sequence index of the destination element in the dstField.

See section 27.2.17 for details on the definition of Field *sequence indices* and *tensor sequence indices*.

[srcTermProcessing] The srcTermProcessing parameter controls how many source terms, located on the same PET and summing into the same destination element, are summed into partial sums on the source PET before being transferred to the destination PET. A value of 0 indicates that the entire arithmetic is done on the destination PET; source elements are neither multiplied by their factors nor added into partial sums before being sent off by the source PET. A value of 1 indicates that source elements are multiplied by their factors on the source side before being sent to the destination PET. Larger values of srcTermProcessing indicate the maximum number of terms in the partial sums on the source side.

Note that partial sums may lead to bit-for-bit differences in the results. See section 35.2.1 for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods.

The ESMF_FieldSMMStore() method implements an auto-tuning scheme for the srcTermProcessing parameter. The intent on the srcTermProcessing argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used for the srcTermProcessing parameter, and the auto-tuning phase is skipped. In this case the srcTermProcessing argument is not modified on return. If the provided argument is < 0, the srcTermProcessing parameter is determined internally using the auto-tuning scheme. In this case the srcTermProcessing argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional srcTermProcessing argument is omitted.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstanding during a sparse matrix exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the restuls. However, it may affect the performance reproducibility of the exchange.

The ESMF_FieldSMMStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified on return. If the provided argument is < 0, the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.65 ESMF_FieldSMMStore - Precompute Field sparse matrix multiplication without local factors

INTERFACE:
! Private name; call using ESMF_FieldSMMStore()
subroutine ESMF_FieldSMMStoreNF(srcField, dstField, &
    routehandle, factorList, factorIndexList, &
    srcTermProcessing, pipelineDepth, rc)

ARGUMENTS:

    type(ESMF_Field), intent(in) :: srcField
    type(ESMF_Field), intent(inout) :: dstField
    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(inout), optional :: srcTermProcessing
    integer, intent(inout), optional :: pipelineDepth
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

6.1.0 Added arguments srcTermProcessing, pipelineDepth The two arguments srcTermProcessing and pipelineDepth provide access to the tuning parameters affecting the sparse matrix execution.

DESCRIPTION:

Store a Field sparse matrix multiplication operation from srcField to dstField. PETs that specify non-zero matrix coefficients must use the \texttt{<type><kind>} overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with 
\texttt{size(factorList) = (/0/)} and \texttt{size(factorIndexList) = (2,0/)} or \texttt{(4,0/)} indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface \texttt{without factorList and factorIndexList arguments}.

Both srcField and dstField are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices. SMM corresponds to an identity mapping of the source Field vector to the destination Field vector.

Source and destination Fields may be of different \texttt{<type><kind>}. Further source and destination Fields may differ in shape, however, the number of elements must match.

It is erroneous to specify the identical Field object for srcField and dstField arguments.

The routine returns an \texttt{ESMF_RouteHandle} that can be used to call \texttt{ESMF_FieldSMM()} on any pair of Fields that are weakly congruent and typekind conform with the srcField, dstField pair. Congruent Fields possess matching DistGrids, and the shape of the local array tiles matches between the Fields for every DE. For weakly congruent Fields the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Fields that differ in the number of elements in the left most undistributed dimensions. Because Grid dimensions are mapped to Field in a sequence order, it's necessary to map the ungridded dimensions to the first set of dimensions in order to use the weakly congruent Field SMM feature. Not providing a non-default gridToFieldMap during Field creation and then using such Fields in a weakly congruent manner in Field communication methods leads to undefined behavior.
This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.
For examples and associated documentations using this method see Section 25.3.32.
The arguments are:

srcField ESMF_Field with source data.
dstField ESMF_Field with destination data. The data in this Field may be destroyed by this call.

routehandle Handle to the precomputed Route.

[srcTermProcessing] The srcTermProcessing parameter controls how many source terms, located on the same
PET and summing into the same destination element, are summed into partial sums on the source PET before
being transferred to the destination PET. A value of 0 indicates that the entire arithmetic is done on the destina-
tion PET; source elements are neither multiplied by their factors nor added into partial sums before being sent
off by the source PET. A value of 1 indicates that source elements are multiplied by their factors on the source
side before being sent to the destination PET. Larger values of srcTermProcessing indicate the maximum
number of terms in the partial sums on the source side.

Note that partial sums may lead to bit-for-bit differences in the results. See section 35.2.1 for an in-depth
discussion of all bit-for-bit reproducibility aspects related to route-based communication methods.
The ESMF_FieldSMMStore() method implements an auto-tuning scheme for the srcTermProcessing
parameter. The intent on the srcTermProcessing argument is "inout" in order to support both
overriding and accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used
for the srcTermProcessing parameter, and the auto-tuning phase is skipped. In this case the
srcTermProcessing argument is not modified on return. If the provided argument is < 0, the
srcTermProcessing parameter is determined internally using the auto-tuning scheme. In this case the
srcTermProcessing argument is re-set to the internally determined value on return. Auto-tuning is also
used if the optional srcTermProcessing argument is omitted.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstand-
ing during a sparse matrix exchange. Larger values of pipelineDepth typically lead to better performance. However,
on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect
the performance reproducibility of the exchange.
The ESMF_FieldSMMStore() method implements an auto-tuning scheme for the pipelineDepth pa-
rameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and
accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used for the pipelineDepth
parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified
on return. If the provided argument is < 0, the pipelineDepth parameter is determined internally using the
auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on
return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.6.66 ESMF_FieldValidate - Check validity of a Field

INTERFACE:
subroutine ESMF_FieldValidate(field, rc)

ARGUMENTS:

  type(ESMF_Field), intent(in) :: field
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Validates that the field is internally consistent. Currently this method determines if the field is uninitialized or already destroyed. It validates the contained array and grid objects. The code also checks if the array and grid sizes agree. This check compares the distgrid contained in array and grid; then it proceeds to compare the computational bounds contained in array and grid.

The method returns an error code if problems are found.

The arguments are:

  field ESMF_Field to validate.

  [rc] Return code; equals ESMF_SUCCESS if the field is valid.

25.6.67 ESMF_FieldWrite - Write Field data into a file

INTERFACE:

  subroutine ESMF_FieldWrite(field, file, &
  variableName, overwrite, status, timeslice, iofmt, rc)

ARGUMENTS:

  type(ESMF_Field), intent(in) :: field
  character(*) , intent(in) :: file
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  character(*), intent(in), optional :: variableName
  logical, intent(in), optional :: overwrite
  type(ESMF_FileStatus_Flag), intent(in), optional :: status
  integer, intent(in), optional :: timeslice
  type(ESMF_IOFmt_Flag), intent(in), optional :: iofmt
  integer, intent(out), optional :: rc

DESCRIPTION:

Write Field data into a file. For this API to be functional, the environment variable ESMF_PIO should be set to "internal" when the ESMF library is built. Please see the section on Data I/O.
- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

**field** The ESMF_Field object that contains data to be written.

**file** The name of the output file to which Field data is written.

**[variableName]** Variable name in the output file; default is the "name" of field. Use this argument only in the IO format (such as NetCDF) that supports variable name. If the IO format does not support this (such as binary format), ESMF will return an error code.

**[overwrite]** A logical flag, the default is .false., i.e., existing field data may not be overwritten. If .true., the overwrite behavior depends on the value of iofmt as shown below:

- iofmt = ESMF_IOFMT_BIN: All data in the file will be overwritten with each field’s data.
- iofmt = ESMF_IOFMT_NETCDF: Only the data corresponding to each field’s name will be overwritten. If the timeslice option is given, only data for the given timeslice may be overwritten. Note that it is always an error to attempt to overwrite a NetCDF variable with data which has a different shape.

**[status]** The file status. Please see Section 50.19 for the list of options. If not present, defaults to ESMF_FILESTATUS_UNKNOWN.

**[timeslice]** Some IO formats (e.g. NetCDF) support the output of data in form of time slices. The timeslice argument provides access to this capability. timeslice must be positive. The behavior of this option may depend on the setting of the overwrite flag:

- overwrite = .false.: If the timeslice value is less than the maximum time already in the file, the write will fail.
- overwrite = .true.: Any positive timeslice value is valid.

By default, i.e. by omitting the timeslice argument, no provisions for time slicing are made in the output file, however, if the file already contains a time axis for the variable, a timeslice one greater than the maximum will be written.

**[iofmt]** The IO format. Please see Section 50.28 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

### 25.7 Class API: Field Utilities

#### 25.7.1 ESMF_GridGetFieldBounds - Get precomputed DE-local Fortran data array bounds for creating a Field from a Grid and Fortran array

**INTERFACE:**

```fortran
subroutine ESMF_GridGetFieldBounds(grid, &
   localDe, staggerloc, gridToFieldMap, &
   ungriddedLBound, ungriddedUBound, &
   totalLWidth, totalUWidth, &
   totalLBound, totalUBound, totalCount, rc)
```

396
ARGUMENTS:

```fortran
  type(ESMF_Grid), intent(in) :: grid
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: localDe
  type(ESMF_StaggerLoc), intent(in), optional :: staggerloc
  integer, intent(in), optional :: gridToFieldMap(:)
  integer, intent(in), optional :: ungriddedLBound(:)
  integer, intent(in), optional :: ungriddedUBound(:)
  integer, intent(in), optional :: totalLWidth(:)
  integer, intent(in), optional :: totalUWidth(:)
  integer, intent(out), optional :: totalLBound(:)
  integer, intent(out), optional :: totalUBound(:)
  integer, intent(out), optional :: totalCount(:)
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Compute the lower and upper bounds of Fortran data array that can later be used in FieldCreate interface to create an ESMF_Field from an ESMF_Grid and the Fortran data array. For an example and associated documentation using this method see section 25.3.9.

The arguments are:

- **grid** ESMF_Grid.
- **localDe** Local DE for which information is requested. [0,..,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.
- **staggerloc** Stagger location of data in grid cells. For valid predefined values and interpretation of results see section 30.2.6.
- **gridToFieldMap** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field.
- **ungriddedLBound** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.
- **ungriddedUBound** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.
[totalLWidth] Lower bound of halo region. The size of this array is the number of dimensions in the grid. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalLWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[totalUWidth] Upper bound of halo region. The size of this array is the number of dimensions in the grid. However, ordering of the elements needs to be the same as they appear in the field. Values default to 0. If values for totalUWidth are specified they must be reflected in the size of the field. That is, for each gridded dimension the field size should be max(totalLWidth + totalUWidth + computationalCount, exclusiveCount).

[totalLBound] The relative lower bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_Grid and Fortran data array. This is an output variable from this user interface.

The relative lower bounds of Fortran data array to be used

[totalUBound] The relative upper bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_Grid and Fortran data array. This is an output variable from this user interface.

[totalCount] Number of elements need to be allocated for Fortran data array to be used later in ESMF_FieldCreate from ESMF_Grid and Fortran data array. This is an output variable from this user interface.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

25.7.2 ESMF_LocStreamGetFieldBounds - Get precomputed DE-local Fortran data array bounds for creating a Field from a LocStream and Fortran array

INTERFACE:

subroutine ESMF_LocStreamGetFieldBounds(locstream, &
localDe, gridToFieldMap, &
ungriddedLBound, ungriddedUBound, &
totalLBound, totalUBound, totalCount, rc)

ARGUMENTS:

type(ESMF_LocStream), intent(in) :: locstream
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: localDe
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(out), optional :: totalLBound(:)
integer, intent(out), optional :: totalUBound(:)
integer, intent(out), optional :: totalCount(:)
integer, intent(out), optional :: rc
DESCRIPTION:

Compute the lower and upper bounds of Fortran data array that can later be used in FieldCreate interface to create a ESMF_Field from a ESMF_LocStream and the Fortran data array. For an example and associated documentation using this method see section 25.3.9.

The arguments are:

- **locstream** ESMF_LocStream.
- **localDe** Local DE for which information is requested. [0,..,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.
- **gridToFieldMap** List with number of elements equal to 1. The list elements map the dimension of the locstream to a dimension in the field by specifying the appropriate field dimension index. The default is to map the locstream's dimension against the lowest dimension of the field in sequence, i.e. gridToFieldMap = (/1/). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field.
- **ungriddedLBound** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than 1, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.
- **ungriddedUBound** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than 1, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.
- **totalLBound** The relative lower bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.
- **totalUBound** The relative upper bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.
- **totalCount** Number of elements need to be allocated for Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.
- **rc** Return code; equals ESMF_SUCCESS if there are no errors.

**25.7.3 ESMF_MeshGetFieldBounds - Get precomputed DE-local Fortran data array bounds for creating a Field from a Mesh and a Fortran array**

**INTERFACE:**

```fortran
subroutine ESMF_MeshGetFieldBounds (mesh, &
   localDe, gridToFieldMap, &
   ungriddedLBound, ungriddedUBound, &
   totalLBound, totalUBound, totalCount, rc)
```
ARGUMENTS:

```fortran
  type(ESMF_Mesh), intent(in) :: mesh
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: localDe
  integer, intent(in), optional :: gridToFieldMap(:)
  integer, intent(in), optional :: ungriddedLBound(:)
  integer, intent(in), optional :: ungriddedUBound(:)
  integer, intent(out), optional :: totalLBound(:)
  integer, intent(out), optional :: totalUBound(:)
  integer, intent(out), optional :: totalCount(:)
  integer, intent(out), optional :: rc
```

DESCRIPTION:

Compute the lower and upper bounds of Fortran data array that can later be used in FieldCreate interface to create a ESMF_Field from a ESMF_Mesh and the Fortran data array. For an example and associated documentation using this method see section 25.3.9.

The arguments are:

**mesh** ESMF_Mesh.

**[localDe]** Local DE for which information is requested. [0,...,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.

**[gridToFieldMap]** List with number of elements equal to the grid's dimCount. The list elements map each dimension of the grid to a dimension in the field by specifying the appropriate field dimension index. The default is to map all of the grid's dimensions against the lowest dimensions of the field in sequence, i.e. gridToFieldMap = (/1,2,3,.../). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. It is erroneous to specify the same gridToFieldMap entry multiple times. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field.

**[ungriddedLBound]** Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[ungriddedUBound]** Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than grid dimension count, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the the ordering of these ungridded dimensions is the same as their order in the field.

**[totalLBound]** The relative lower bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_Mesh and Fortran data array. This is an output variable from this user interface.

**[totalUBound]** The relative upper bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_Mesh and Fortran data array. This is an output variable from this user interface.

**[totalCount]** Number of elements need to be allocated for Fortran data array to be used later in ESMF_FieldCreate from ESMF_Mesh and Fortran data array. This is an output variable from this user interface.

400
Return code; equals ESMF_SUCCESS if there are no errors.

25.7.4 ESMF_XGridGetFieldBounds - Get precomputed DE-local Fortran data array bounds for creating a Field from an XGrid and a Fortran array

INTERFACE:

subroutine ESMF_XGridGetFieldBounds(xgrid, &
xgridside, gridindex, localDe, gridToFieldMap, &
ungriddedLBound, ungriddedUBound, &
totalLBound, totalUBound, totalCount, rc)

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_XGridSide_Flag), intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
integer, intent(in), optional :: localDe
integer, intent(in), optional :: gridToFieldMap(:)
integer, intent(in), optional :: ungriddedLBound(:)
integer, intent(in), optional :: ungriddedUBound(:)
integer, intent(in), optional :: totalLBound(:)
integer, intent(in), optional :: totalUBound(:)
integer, intent(in), optional :: totalCount(:)
integer, intent(out), optional :: rc

DESCRIPTION:

Compute the lower and upper bounds of Fortran data array that can later be used in FieldCreate interface to create an ESMF_Field from a ESMF_XGrid and the Fortran data array. For an example and associated documentation using this method see section 25.3.9.

The arguments are:

xgrid ESMF_XGrid object.

[xgridside] Which side of the XGrid to create the Field on (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

[gridindex] If xgridside is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index tells which Grid on that side to create the Field on. If not provided, defaults to 1.

[localDe] Local DE for which information is requested. [0,..,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.

[gridToFieldMap] List with number of elements equal to 1. The list elements map the dimension of the locstream to a dimension in the field by specifying the appropriate field dimension index. The default is to map the
locstream's dimension against the lowest dimension of the field in sequence, i.e. gridToFieldMap = (1/1). The values of all gridToFieldMap entries must be greater than or equal to one and smaller than or equal to the field rank. The total ungridded dimensions in the field are the total field dimensions less the dimensions in the grid. Ungridded dimensions must be in the same order they are stored in the field.

[ungriddedLBound] Lower bounds of the ungridded dimensions of the field. The number of elements in the ungriddedLBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than 1, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

[ungriddedUBound] Upper bounds of the ungridded dimensions of the field. The number of elements in the ungriddedUBound is equal to the number of ungridded dimensions in the field. All ungridded dimensions of the field are also undistributed. When field dimension count is greater than 1, both ungriddedLBound and ungriddedUBound must be specified. When both are specified the values are checked for consistency. Note that the ordering of these ungridded dimensions is the same as their order in the field.

[totalLBound] The relative lower bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.

[totalUBound] The relative upper bounds of Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.

[totalCount] Number of elements need to be allocated for Fortran data array to be used later in ESMF_FieldCreate from ESMF_LocStream and Fortran data array. This is an output variable from this user interface.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26 ArrayBundle Class

26.1 Description

The ESMF_ArrayBundle class allows a set of Arrays to be bundled into a single object. The Arrays in an ArrayBundle may be of different type, kind, rank and distribution. Besides ease of use resulting from bundling, the ArrayBundle class offers the opportunity for performance optimization when operating on a bundle of Arrays as a single entity. Communication methods are especially good candidates for performance optimization. Best optimization results are expected for ArrayBundles that contain Arrays that share a common distribution, i.e. DistGrid, and are of same type, kind and rank.

ArrayBundles are one of the data objects that can be added to States, which are used for providing to or receiving data from other Components.

26.2 Use and Examples

Examples of creating, destroying and accessing ArrayBundles and their constituent Arrays are provided in this section, along with some notes on ArrayBundle methods.

26.2.1 Creating an ArrayBundle from a list of Arrays

An ArrayBundle is created from a list of ESMF_Array objects.
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
   regDecomp=(/2,3/), rc=rc)

allocate(arrayList(2))
arrayList(1) = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
   rc=rc)

arrayList(2) = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
   rc=rc)

Now arrayList is used to create an ArrayBundle object.

arraybundle = ESMF_ArrayBundleCreate(arrayList=arrayList, &
   name="MyArrayBundle", rc=rc)

Here the temporary arrayList can be deallocated. This will not affect the ESMF Array objects inside the ArrayBundle. However, the Array objects must not be deallocated while the ArrayBundle references them.

deallocate(arrayList)

26.2.2 Adding, removing, replacing Arrays in the ArrayBundle

Individual Arrays can be added using the Fortran array constructor syntax (/ ... /). Here an ESMF_Array is created on the fly and immediately added to the ArrayBundle.

call ESMF_ArrayBundleAdd(arraybundle, arrayList=(/ &
   ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, name="AonFly")/), &
   rc=rc)

Items in the ArrayBundle can be replaced by items with the same name.

call ESMF_ArraySpecSet(arrayspec2, typekind=ESMF_TYPEKIND_R4, rank=2, rc=rc)

call ESMF_ArrayBundleReplace(arraybundle, arrayList=(/ &
   ESMF_ArrayCreate(arrayspec=arrayspec2, distgrid=distgrid, name="AonFly")/), &
   rc=rc)

Items can be removed from the ArrayBundle by providing their name.
call ESMF_ArrayBundleRemove(arraybundle, arrayNameList=("AonFly"), rc=rc)

The ArrayBundle AddReplace() method can be used to conveniently add an item to the ArrayBundle, or replacing an existing item of the same name.

call ESMF_ArrayBundleAddReplace(arraybundle, arrayList=( &
    ESMF_ArrayCreate(arrayspec=arrayspec2, distgrid=distgrid, name="AonFly"), &
    rc=rc)

The ArrayBundle object can be printed at any time to list its contents by name.

call ESMF_ArrayBundlePrint(arraybundle, rc=rc)

26.2.3 Accessing Arrays inside the ArrayBundle

Individual items in the ArrayBundle can be accessed directly by their name.

call ESMF_ArrayBundleGet(arraybundle, arrayName="AonFly", array=arrayOut, &
  rc=rc)

A list containing all of the Arrays in the ArrayBundle can also be requested in a single call. This requires that a large enough list argument is passed into the ESMF_ArrayBundleGet() method. The exact number of items in the ArrayBundle can be queried using the arrayCount argument first.

call ESMF_ArrayBundleGet(arraybundle, arrayCount=arrayCount, rc=rc)

Then use arrayCount to correctly allocate the arrayList variable for a second call to ESMF_ArrayBundleGet().

allocate(arrayList(arrayCount))
call ESMF_ArrayBundleGet(arraybundle, arrayList=arrayList, rc=rc)

Now the arrayList variable can be used to access the individual Arrays, e.g. to print them.

do i=1, arrayCount
    call ESMF_ArrayPrint(arrayList(i), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endo

By default the arrayList returned by ESMF_ArrayBundleGet() contains the items in alphabetical order. To instead return the items in the same order in which they were added to the ArrayBundle, the itemorderflag argument is passed with a value of ESMF_ITEMORDER_ADDORDER.

call ESMF_ArrayBundleGet(arraybundle, arrayList=arrayList, &
  itemorderflag=ESMF_ITEMORDER_ADDORDER, rc=rc)
26.2.4 Destroying an ArrayBundle and its constituents

Destroying an ArrayBundle does not destroy the Arrays. In fact, it leaves the Arrays totally unchanged.

```call ESMF_ArrayBundleDestroy(arraybundle, rc=rc)```

The Arrays must be destroyed separately.

```call ESMF_ArrayDestroy(arrayList(1), rc=rc)```

```call ESMF_ArrayDestroy(arrayList(2), rc=rc)```

```deallocate(arrayList)```

```call ESMF_DistGridDestroy(distgrid, rc=rc)```

26.2.5 Halo communication

One of the most fundamental communication pattern in domain decomposition codes is the *halo* operation. The ESMF Array class supports halos by allowing memory for extra elements to be allocated on each DE. See section 27.2.14 for a discussion of the Array level halo operation. The ArrayBundle level extents the Array halo operation to bundles of Arrays.

First create an `ESMF_ArrayBundle` object containing a set of ESMF Arrays.

```arraybundle = ESMF_ArrayBundleCreate(arrayList=arrayList, &
   name="MyArrayBundle", rc=rc)```

The ArrayBundle object can be treated as a single entity. The `ESMF_ArrayBundleHaloStore()` call determines the most efficient halo exchange pattern for *all* Arrays that are part of `arraybundle`.

```call ESMF_ArrayBundleHaloStore(arraybundle=arraybundle, &
   routehandle=haloHandle, rc=rc)```

The halo exchange pattern stored in `haloHandle` can now be applied to the `arraybundle` object, or any other ArrayBundle that is weakly congruent to the one used during the `ESMF_ArrayBundleHaloStore()` call.

```call ESMF_ArrayBundleHalo(arraybundle=arraybundle, routehandle=haloHandle, &
   rc=rc)```

Finally, when no longer needed, the resources held by `haloHandle` need to be returned to the system by calling `ESMF_ArrayBundleHaloRelease()`.
call ESMF_ArrayBundleHaloRelease(routehandle=haloHandle, rc=rc)

Finally the ArrayBundle object can be destroyed.

call ESMF_ArrayBundleDestroy(arraybundle, rc=rc)

26.3 Restrictions and Future Work

- **Non-blocking** ArrayBundle communications option is not yet implemented. In the future this functionality will be provided via the `routesyncflag` option.

26.4 Design and Implementation Notes

The following is a list of implementation specific details about the current ESMF ArrayBundle.

- Implementation language is C++.
- All precomputed communication methods are based on sparse matrix multiplication.

26.5 Class API

26.5.1 ESMF_ArrayBundleAssignment(=) - ArrayBundle assignment

**INTERFACE:**

```plaintext
interface assignment (=)
arraybundle1 = arraybundle2
```

**ARGUMENTS:**

```plaintext
type (ESMF_ArrayBundle) :: arraybundle1
type (ESMF_ArrayBundle) :: arraybundle2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Assign `arraybundle1` as an alias to the same ESMF ArrayBundle object in memory as `arraybundle2`. If `arraybundle2` is invalid, then `arraybundle1` will be equally invalid after the assignment.

The arguments are:
arraybundle1 The ESMF_ArrayBundle object on the left hand side of the assignment.
arraybundle2 The ESMF_ArrayBundle object on the right hand side of the assignment.

26.5.2 ESMF_ArrayBundleOperator(==) - ArrayBundle equality operator

INTERFACE:

```latex
interface operator(==)
    if (arraybundle1 == arraybundle2) then ... endif
    OR
    result = (arraybundle1 == arraybundle2)
end interface
```

RETURN VALUE:

```latex
logical :: result
```

ARGUMENTS:

```latex
type(ESMF_ArrayBundle), intent(in) :: arraybundle1
type(ESMF_ArrayBundle), intent(in) :: arraybundle2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether arraybundle1 and arraybundle2 are valid aliases to the same ESMF ArrayBundle object in memory. For a more general comparison of two ESMF ArrayBundles, going beyond the simple alias test, the ESMF_ArrayBundleMatch() function (not yet implemented) must be used.

The arguments are:

arraybundle1 The ESMF_ArrayBundle object on the left hand side of the equality operation.
arraybundle2 The ESMF_ArrayBundle object on the right hand side of the equality operation.

26.5.3 ESMF_ArrayBundleOperator(/=) - ArrayBundle not equal operator

INTERFACE:
interface operator(/=)
    if (arraybundle1 /= arraybundle2) then ... endif
    OR
    result = (arraybundle1 /= arraybundle2)
end interface

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_ArrayBundle), intent(in) :: arraybundle1
    type(ESMF_ArrayBundle), intent(in) :: arraybundle2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether arraybundle1 and arraybundle2 are not valid aliases to the same ESMF ArrayBundle object in memory. For a more general comparison of two ESMF ArrayBundles, going beyond the simple alias test, the ESMF_ArrayBundleMatch() function (not yet implemented) must be used.

The arguments are:

arraybundle1  The ESMF_ArrayBundle object on the left hand side of the non-equality operation.
arraybundle2  The ESMF_ArrayBundle object on the right hand side of the non-equality operation.

26.5.4 ESMF_ArrayBundleAdd - Add Arrays to an ArrayBundle

INTERFACE:

    subroutine ESMF_ArrayBundleAdd(arraybundle, arrayList, &
        multiflag, relaxedflag, rc)

ARGUMENTS:

    type(ESMF_ArrayBundle), intent(inout) :: arraybundle
    type(ESMF_Array), intent(in) :: arrayList(:)
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: multiflag
    logical, intent(in), optional :: relaxedflag
    integer, intent(out), optional :: rc

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Add Array(s) to an ArrayBundle. It is an error if `arrayList` contains Arrays that match by name Arrays already contained in `arraybundle`.

arraybundle  ESMF_ArrayBundle to be added to.
arrayList  List of ESMF_Array objects to be added.

[multiflag] A setting of `.true.` allows multiple items with the same name to be added to `arraybundle`. For `.false.`, added items must have unique names. The default setting is `.false.`.

[relaxedflag] A setting of `.true.` indicates a relaxed definition of "add" under `multiflag=.false.` mode, where it is not an error if `arrayList` contains items with names that are also found in `arraybundle`. The `arraybundle` is left unchanged for these items. For `.false.` this is treated as an error condition. The default setting is `.false.`.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.5  ESMF_ArrayBundleAddReplace - Conditionally add or replace Arrays in an ArrayBundle

INTERFACE:

```fortran
subroutine ESMF_ArrayBundleAddReplace(arraybundle, arrayList, rc)
```

ARGUMENTS:

```fortran
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_Array), intent(in) :: arrayList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Arrays in `arrayList` that do not match any Arrays by name in `arraybundle` are added to the ArrayBundle. Arrays in `arraybundle` that match by name Arrays in `arrayList` are replaced by those Arrays.

arraybundle  ESMF_ArrayBundle to be manipulated.
arrayList  List of ESMF_Array objects to be added or used as replacement.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.
26.5.6 ESMF_ArrayBundleCreate - Create an ArrayBundle from a list of Arrays

INTERFACE:

    function ESMF_ArrayBundleCreate(arrayList, multiflag, &
        relaxedflag, name, rc)

RETURN VALUE:

    type(ESMF_ArrayBundle) :: ESMF_ArrayBundleCreate

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Array), intent(in), optional :: arrayList(:)
    logical, intent(in), optional :: multiflag
    logical, intent(in), optional :: relaxedflag
    character(len=*), intent(in), optional :: name
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_ArrayBundle object from a list of existing Arrays.

The creation of an ArrayBundle leaves the bundled Arrays unchanged, they remain valid individual objects. An ArrayBundle is a light weight container of Array references. The actual data remains in place, there are no data movements or duplications associated with the creation of an ArrayBundle.

[arrayList] List of ESMF_Array objects to be bundled.

[multiflag] A setting of .true. allows multiple items with the same name to be added to arraybundle. For .false. added items must have unique names. The default setting is .false..

[relaxedflag] A setting of .true. indicates a relaxed definition of "add" under multiflag=.false. mode, where it is not an error if arrayList contains items with names that are also found in arraybundle. The arraybundle is left unchanged for these items. For .false. this is treated as an error condition. The default setting is .false..

[name] Name of the created ESMF_ArrayBundle. A default name is generated if not specified.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
26.5.7 ESMF_ArrayBundleDestroy - Release resources associated with an ArrayBundle

INTERFACE:

subroutine ESMF_ArrayBundleDestroy(arraybundle, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(inout) :: arraybundle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroys an ESMF_ArrayBundle object. The member Arrays are not touched by this operation and remain valid objects that need to be destroyed individually if necessary.

The arguments are:

arraybundle ESMF_ArrayBundle object to be destroyed.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.8 ESMF_ArrayBundleGet - Get object-wide information from an ArrayBundle

INTERFACE:

! Private name; call using ESMF_ArrayBundleGet()
subroutine ESMF_ArrayBundleGetListAll(arraybundle, &
   itemorderflag, arrayCount, arrayList, arrayNameList, name, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(in) :: arraybundle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_ItemOrder_Flag), intent(in), optional :: itemorderflag
integer, intent(out), optional :: arrayCount
character(len=*) , intent(out), optional :: arrayList(:)
character(len=*) , intent(out), optional :: arrayNameList(:)
integer, intent(out), optional :: name
integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added argument itemorderflag. The new argument gives the user control over the order in which the items are returned.

DESCRIPTION:

Get general, i.e. not Array name specific information from the ArrayBundle.

arraybundle  ESMF_ArrayBundle to be queried.

[itemorderflag] Specifies the order of the returned items in the arrayList and arrayNameList. The default is ESMF_ITEMORDER_ABC. See \[50.30\] for a full list of options.

[arrayCount] Upon return holds the number of Arrays bundled in the ArrayBundle.

[arrayList] Upon return holds a list of Arrays bundled in arraybundle. The argument must be allocated to be at least of size arrayCount.

[arrayNameList] Upon return holds a list of the names of the Arrays bundled in arraybundle. The argument must be allocated to be at least of size arrayCount.

[name] Name of the ArrayBundle object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.9  ESMF_ArrayBundleGet - Get information about an Array by name and optionally return an Array

INTERFACE:

! Private name; call using ESMF_ArrayBundleGet()
subroutine ESMF_ArrayBundleGetItem(arraybundle, arrayName, 
array, arrayCount, isPresent, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(in) :: arraybundle
character(len=*), intent(in) :: arrayName
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Array), intent(out), optional :: array
integer, intent(out), optional :: arrayCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get information about items that match arrayName in ArrayBundle.

arraybundle  ESMF_ArrayBundle to be queried.
arrayName  Specified name.

[array]  Upon return holds the requested Array item. It is an error if this argument was specified and there is not exactly one Array item in arraybundle that matches arrayName.

[arrayCount]  Number of Arrays with arrayName in arraybundle.

[isPresent]  Upon return indicates whether Array(s) with arrayName exist in arraybundle.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.10  ESMF_ArrayBundleGet - Get a list of Arrays by name

INTERFACE:

! Private name; call using ESMF_ArrayBundleGet()
subroutine ESMF_ArrayBundleGetList(arraybundle, arrayName, arrayList, &
   itemorderflag, rc)

ARGUMENTS:

  type(ESMF_ArrayBundle),  intent(in) :: arraybundle
  character(len=*),          intent(in) :: arrayName
  type(ESMF_Array),           intent(out) :: arrayList(:)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_ItemOrder_Flag), intent(in), optional :: itemorderflag
  integer,                     intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:
6.1.0 Added argument itemorderflag. The new argument gives the user control over the order in which the items are returned.

DESCRIPTION:

Get the list of Arrays from ArrayBundle that match arrayName.

**arraybundle** ESMF_ArrayBundle to be queried.

**arrayName** Specified name.

**arrayList** List of Arrays in arraybundle that match arrayName. The argument must be allocated to be at least of size arrayCount returned for this arrayName.

[itemorderflag] Specifies the order of the returned items in the arrayList. The default is ESMF_ITEMORDER_ABC. See 50.30 for a full list of options.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

26.5.11 ESMF_ArrayBundleHalo - Execute an ArrayBundle halo operation

**INTERFACE:**

```fortran
subroutine ESMF_ArrayBundleHalo(arraybundle, routehandle, &
   checkflag, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
   logical, intent(in), optional :: checkflag
   integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Execute a precomputed ArrayBundle halo operation for the Arrays in arrayBundle.

See ESMF_ArrayBundleHaloStore() on how to precompute routehandle.

This call is collective across the current VM.

**arraybundle** ESMF_ArrayBundle containing data to be haloed.
routehandle  Handle to the precomputed Route.

[checkflag]  If set to .TRUE., the input Array pairs will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.12  ESMF_ArrayBundleHaloRelease - Release resources associated with an ArrayBundle halo operation

INTERFACE:

    subroutine ESMF_ArrayBundleHaloRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an ArrayBundle halo operation. After this call routehandle becomes invalid.

routehandle  Handle to the precomputed Route.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.13  ESMF_ArrayBundleHaloStore - Precompute an ArrayBundle halo operation

INTERFACE:

    subroutine ESMF_ArrayBundleHaloStore(arraybundle, routehandle, &
    startregion, haloLDepth, haloUDepth, rc)

ARGUMENTS:
type (ESMF_ArrayBundle), intent(inout) :: arraybundle

type (ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

-- type (ESMF_StartRegion_Flag), intent(in), optional :: startregion
integer, intent(in), optional :: haloLDepth(:)
integer, intent(in), optional :: haloUDepth(:)
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store an ArrayBundle halo operation over the data in arraybundle. By default, i.e. without specifying startregion, haloLDepth and haloUDepth, all elements in the total Array regions that lie outside the exclusive regions will be considered potential destination elements for halo. However, only those elements that have a corresponding halo source element, i.e. an exclusive element on one of the DEs, will be updated under the halo operation. Elements that have no associated source remain unchanged under halo.

Specifying startregion allows to change the shape of the effective halo region from the inside. Setting this flag to ESMF_STARTREGION_COMPUTATIONAL means that only elements outside the computational region for each Array are considered for potential destination elements for halo. The default is ESMF_STARTREGION_EXCLUSIVE.

The haloLDepth and haloUDepth arguments allow to reduce the extent of the effective halo region. Starting at the region specified by startregion, the haloLDepth and haloUDepth define a halo depth in each direction. Note that the maximum halo region is limited by the total region for each Array, independent of the actual haloLDepth and haloUDepth setting. The total Array regions are local DE specific. The haloLDepth and haloUDepth are interpreted as the maximum desired extent, reducing the potentially larger region available for halo.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayBundleHalo() on any ArrayBundle that is weakly congruent and typekind conform to arraybundle. Congruency for ArrayBundles is given by the congruency of its constituents. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

arraybundle  ESMF_ArrayBundle containing data to be haloed. The data in the halo regions may be destroyed by this call.

routehandle  Handle to the precomputed Route.

[startregion] The start of the effective halo region on every DE. The default setting is ESMF_STARTREGION_EXCLUSIVE, rendering all non-exclusive elements potential halo destination elements. See section [50.47] for a complete list of valid settings.

[haloLDepth] This vector specifies the lower corner of the effective halo region with respect to the lower corner of startregion. The size of haloLDepth must equal the number of distributed Array dimensions.

[haloUDepth] This vector specifies the upper corner of the effective halo region with respect to the upper corner of startregion. The size of haloUDepth must equal the number of distributed Array dimensions.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
26.5.14 ESMF_ArrayBundlePrint - Print ArrayBundle information

INTERFACE:

    subroutine ESMF_ArrayBundlePrint(arraybundle, rc)

ARGUMENTS:

    type(ESMF_ArrayBundle), intent(in) :: arraybundle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Print internal information of the specified ESMF_ArrayBundle object to stdout.

The arguments are:

arraybundle ESMF_ArrayBundle object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.15 ESMF_ArrayBundleRead - Read Arrays to an ArrayBundle from file(s)

INTERFACE:

    subroutine ESMF_ArrayBundleRead(arraybundle, file, &
    singleFile, timeslice, iofmt, rc)

ARGUMENTS:

    type(ESMF_ArrayBundle), intent(inout) :: arraybundle
    character(*), intent(in) :: file
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: singleFile
    integer, intent(in), optional :: timeslice
    type(ESMF_IOFmt_Flag), intent(in), optional :: iofmt
    integer, intent(out), optional :: rc
DESCRIPTION:

Read Array data to an ArrayBundle object from file(s). For this API to be functional, the environment variable `ESMF_PIO` should be set to "internal" when the ESMF library is built. Please see the section on Data I/O, 36.3.

Limitations:

- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

`arraybundle` An ESMF_ArrayBundle object.

`file` The name of the file from which ArrayBundle data is read.

`[singleFile]` A logical flag, the default is .true., i.e., all Arrays in the bundle are stored in one single file. If .false., each Array is stored in separate files; these files are numbered with the name based on the argument "file". That is, a set of files are named: [file_name]001, [file_name]002, [file_name]003,...

`[timeslice]` The time-slice number of the variable read from file.

`[iofmt]` The IO format. Please see Section 50.26 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

`[rc]` Return code; equals ESMF_SUCCESS if there are no errors.

26.5.16 ESMF_ArrayBundleRedist - Execute an ArrayBundle redistribution

INTERFACE:

```fortran
subroutine ESMF_ArrayBundleRedist(srcArrayBundle, dstArrayBundle, &
    routehandle, checkflag, rc)
ARGUMENTS:
```

```fortran
type(ESMF_ArrayBundle), intent(in), optional :: srcArrayBundle

type(ESMF_ArrayBundle), intent(inout), optional :: dstArrayBundle

type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
logical, intent(in), optional :: checkflag
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Execute a precomputed ArrayBundle redistribution from the Arrays in srcArrayBundle to the Arrays in dstArrayBundle.

The srcArrayBundle and dstArrayBundle arguments are optional in support of the situation where srcArrayBundle and/or dstArrayBundle are not defined on all PETs. The srcArrayBundle and dstArrayBundle must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

This call is collective across the current VM.

[srcArrayBundle] ESMF_ArrayBundle with source data.
[dstArrayBundle] ESMF_ArrayBundle with destination data.
routehandle Handle to the precomputed Route.
[checkflag] If set to .TRUE. the input Array pairs will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.17 ESMF_ArrayBundleRedistRelease - Release resources associated with ArrayBundle redistribution

INTERFACE:

    subroutine ESMF_ArrayBundleRedistRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an ArrayBundle redistribution. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.
26.5.18  ESMF_ArrayBundleRedistStore - Precompute an ArrayBundle redistribution with local factor argument

INTERFACE:

! Private name; call using ESMF_ArrayBundleRedistStore()

subroutine ESMF_ArrayBundleRedistStore<type><kind>(srcArrayBundle, &
         dstArrayBundle, routehandle, factor, srcToDstTransposeMap, rc)

ARGUMENTS:

type(ESMF_ArrayBundle),  intent(in)                :: srcArrayBundle

type(ESMF_ArrayBundle),  intent(inout)             :: dstArrayBundle

type(ESMF_RouteHandle),  intent(inout)             :: routehandle

<type>(ESMF_KIND_<kind>),  intent(in)              :: factor

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

integer,      intent(in),  optional :: srcToDstTransposeMap(:)

integer,      intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store an ArrayBundle redistribution operation from srcArrayBundle to dstArrayBundle. The redistribution between ArrayBundles is defined as the sequence of individual Array redistributions over all source and destination Array pairs in sequence. The method requires that srcArrayBundle and dstArrayBundle reference an identical number of ESMF_Array objects.

The effect of this method on ArrayBundles that contain aliased members is undefined.

PETs that specify a factor argument must use the <type><kind> overloaded interface. Other PETs call into the interface without factor argument. If multiple PETs specify the factor argument its type and kind as well as its value must match across all PETs. If none of the PETs specifies a factor argument the default will be a factor of 1.

See the description of method ESMF_ArrayRedistStore() for the definition of the Array based operation.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayBundleRedist() on any pair of ArrayBundles that are weakly congruent and typekind conform with the Arrays contained in srcArrayBundle and dstArrayBundle. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

srcArrayBundle  ESMF_ArrayBundle with source data.
dstArrayBundle  ESMF_ArrayBundle with destination data. The data in these Arrays may be destroyed by this call.

routehandle  Handle to the precomputed Route.

factor  Factor by which to multiply source data.

[srcToDstTransposeMap]  List with as many entries as there are dimensions in the Arrays in srcArrayBundle. Each entry maps the corresponding source Array dimension against the specified destination Array dimension. Mixing of distributed and undistributed dimensions is supported.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.19  ESMF_ArrayBundleRedistStore - Precompute an ArrayBundle redistribution without local factor argument

INTERFACE:

! Private name; call using ESMF_ArrayBundleRedistStore()
subroutine ESMF_ArrayBundleRedistStoreNF(srcArrayBundle, dstArrayBundle, &
routehandle, srcToDstTransposeMap, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(in) :: srcArrayBundle

type(ESMF_ArrayBundle), intent(inout) :: dstArrayBundle

type(ESMF_RouteHandle), intent(inout) :: routehandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: srcToDstTransposeMap(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store an ArrayBundle redistribution operation from srcArrayBundle to dstArrayBundle. The redistribution between ArrayBundles is defined as the sequence of individual Array redistributions over all source and destination Array pairs in sequence. The method requires that srcArrayBundle and dstArrayBundle reference an identical number of ESMF_Array objects.

The effect of this method on ArrayBundles that contain aliased members is undefined.

PETs that specify a factor argument must use the <type><kind> overloaded interface. Other PETs call into the interface without factor argument. If multiple PETs specify the factor argument its type and kind as well as its value must match across all PETs. If none of the PETs specifies a factor argument the default will be a factor of 1.

See the description of method ESMF_ArrayRedistStore() for the definition of the Array based operation.
The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayBundleRedist() on any pair of ArrayBundles that are weakly congruent and typekind conform with the Arrays contained in srcArrayBundle and dstArrayBundle. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

srcArrayBundle ESMF_ArrayBundle with source data.

dstArrayBundle ESMF_ArrayBundle with destination data. The data in these Arrays may be destroyed by this call.

routehandle Handle to the precomputed Route.

[srcToDstTransposeMap] List with as many entries as there are dimensions in the Arrays in srcArrayBundle. Each entry maps the corresponding source Array dimension against the specified destination Array dimension. Mixing of distributed and undistributed dimensions is supported.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.20 ESMF_ArrayBundleRemove - Remove Arrays from ArrayBundle

INTERFACE:

subroutine ESMF_ArrayBundleRemove(arraybundle, arrayNameList, &
multiflag, relaxedflag, rc)

ARGUMENTS:

  type(ESMF_ArrayBundle), intent(inout) :: arraybundle
  character(len=*), intent(in) :: arrayNameList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical, intent(in), optional :: multiflag
  logical, intent(in), optional :: relaxedflag
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Remove Array(s) by name from ArrayBundle. In the relaxed setting it is not an error if arrayNameList contains names that are not found in arraybundle.
arraybundle  ESMF_ArrayBundle from which to remove items.
arrayNameList  List of items to remove.

[multiflag]  A setting of .true. allows multiple Arrays with the same name to be removed from arraybundle. For .false., items to be removed must have unique names. The default setting is .false..

[relaxedflag]  A setting of .true. indicates a relaxed definition of "remove" where it is not an error if arrayNameList contains item names that are not found in arraybundle. For .false., this is treated as an error condition. Further, in multiflag=.false. mode, the relaxed definition of "remove" also covers the case where there are multiple items in arraybundle that match a single entry in arrayNameList. For relaxedflag=.false. this is treated as an error condition. The default setting is .false..

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.21  ESMF_ArrayBundleReplace - Replace Arrays in ArrayBundle

INTERFACE:

subroutine ESMF_ArrayBundleReplace(arraybundle, arrayList, &
   multiflag, relaxedflag, rc)

ARGUMENTS:

   type(ESMF_ArrayBundle), intent(inout)   :: arraybundle
   type(ESMF_Array),     intent(in)        :: arrayList(:)
   logical,               intent(in), optional :: multiflag
   logical,               intent(in), optional :: relaxedflag
   integer,               intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Replace Array(s) by name in ArrayBundle. In the relaxed setting it is not an error if arrayList contains Arrays that do not match by name any item in arraybundle. These Arrays are simply ignored in this case.

arraybundle  ESMF_ArrayBundle in which to replace items.
arrayList   List of items to replace.

[multiflag]  A setting of .true. allows multiple items with the same name to be replaced in arraybundle. For .false., items to be replaced must have unique names. The default setting is .false..

423
[relaxedflag] A setting of .true. indicates a relaxed definition of "replace" where it is not an error if arrayList contains items with names that are not found in arraybundle. These items in arrayList are ignored in the relaxed mode. For .false. this is treated as an error condition. Further, in multiflag=.false. mode, the relaxed definition of "replace" also covers the case where there are multiple items in arraybundle that match a single entry by name in arrayList. For relaxedflag=.false. this is treated as an error condition. The default setting is .false..

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.22 ESMF_ArrayBundleSMM - Execute an ArrayBundle sparse matrix multiplication

INTERFACE:

subroutine ESMF_ArrayBundleSMM(srcArrayBundle, dstArrayBundle, &
    routehandle, zeroregion, checkflag, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(in), optional :: srcArrayBundle
    type(ESMF_ArrayBundle), intent(inout), optional :: dstArrayBundle
    type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Region_Flag), intent(in), optional :: zeroregion
    logical, intent(in), optional :: checkflag
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Execute a precomputed ArrayBundle sparse matrix multiplication from the Arrays in srcArrayBundle to the Arrays in dstArrayBundle.

The srcArrayBundle and dstArrayBundle arguments are optional in support of the situation where srcArrayBundle and/or dstArrayBundle are not defined on all PETs. The srcArrayBundle and dstArrayBundle must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

This call is collective across the current VM.

[srcArrayBundle] ESMF_ArrayBundle with source data.

[dstArrayBundle] ESMF_ArrayBundle with destination data.

routehandle Handle to the precomputed Route.
If set to ESMF_REGION_TOTAL (default) the total regions of all DEs in all Arrays in dstArrayBundle will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to ESMF_REGION_EMPTY the elements in the Arrays in dstArrayBundle will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting zeroregion to ESMF_REGION_SELECT will only zero out those elements in the destination Arrays that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.

checkflag
If set to .TRUE. the input Array pairs will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

rc
Return code; equals ESMF_SUCCESS if there are no errors.

26.5.23  ESMF_ArrayBundleSMMRelease - Release resources associated with ArrayBundle sparse matrix multiplication

INTERFACE:

```fortran
subroutine ESMF_ArrayBundleSMMRelease(routehandle, rc)
```

ARGUMENTS:

- `type(ESMF_RouteHandle), intent(inout) :: routehandle`
- `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an ArrayBundle sparse matrix multiplication. After this call `routehandle` becomes invalid.

`routehandle` Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

26.5.24  ESMF_ArrayBundleSMMStore - Precompute an ArrayBundle sparse matrix multiplication with local factors

INTERFACE:
! Private name; call using ESMF_ArrayBundleSMMStore()
subroutine ESMF_ArrayBundleSMMStore(type<kind>>(srcArrayBundle, &
dstArrayBundle, routehandle, factorList, factorIndexList, rc)

ARGUMENTS:

  type(ESMF_ArrayBundle), intent(in) :: srcArrayBundle
  type(ESMF_ArrayBundle), intent(inout) :: dstArrayBundle
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  <type>(ESMF_KIND_<kind>), target, intent(in) :: factorList(:)
  integer, intent(in) :: factorIndexList(:,:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store an ArrayBundle sparse matrix multiplication operation from srcArrayBundle to dstArrayBundle. The sparse matrix multiplication between ArrayBundles is defined as the sequence of individual Array sparse matrix multiplications over all source and destination Array pairs in sequence. The method requires that srcArrayBundle and dstArrayBundle reference an identical number of ESMF_Array objects.

The effect of this method on ArrayBundles that contain aliased members is undefined.

PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

See the description of method ESMF_ArraySMMStore() for the definition of the Array based operation.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayBundleSMM() on any pair of ArrayBundles that are weakly congruent and typekind conform with the Arrays contained in srcArrayBundle and dstArrayBundle. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

srcArrayBundle ESMF_ArrayBundle with source data.

dstArrayBundle ESMF_ArrayBundle with destination data. The data in these Arrays may be destroyed by this call.

routehandle Handle to the precomputed Route.
factorList  List of non-zero coefficients.

factorIndexList  Pairs of sequence indices for the factors stored in factorList.

The second dimension of factorIndexList steps through the list of pairs, i.e. size(factorIndexList,2) == size(factorList). The first dimension of factorIndexList is either of size 2 or size 4.

In the size 2 format factorIndexList(1,:) specifies the sequence index of the source element in the source Array while factorIndexList(2,:) specifies the sequence index of the destination element in the destination Array. For this format to be a valid option source and destination Arrays must have matching number of tensor elements (the product of the sizes of all Array tensor dimensions). Under this condition an identity matrix can be applied within the space of tensor elements for each sparse matrix factor.

The size 4 format is more general and does not require a matching tensor element count. Here the factorIndexList(1,:) specifies the sequence index while factorIndexList(2,:) specifies the tensor sequence index of the source element in the source Array. Further factorIndexList(3,:) specifies the sequence index and factorIndexList(4,:) specifies the tensor sequence index of the destination element in the destination Array.

See section 27.2.17 for details on the definition of Array sequence indices and tensor sequence indices.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

26.5.25  ESMF_ArrayBundleSMMStore - Precompute an ArrayBundle sparse matrix multiplication without local factors

INTERFACE:

! Private name; call using ESMF_ArrayBundleSMMStore()
subroutine ESMF_ArrayBundleSMMStoreNF(srcArrayBundle, dstArrayBundle, &
  routeHandle, rc)

ARGUMENTS:

  type(ESMF_ArrayBundle), intent(in) :: srcArrayBundle
  type(ESMF_ArrayBundle), intent(inout) :: dstArrayBundle
  type(ESMF_RouteHandle), intent(inout) :: routeHandle

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Store an ArrayBundle sparse matrix multiplication operation from srcArrayBundle to dstArrayBundle. The sparse matrix multiplication between ArrayBundles is defined as the sequence of individual Array sparse matrix multiplications over all source and destination Array pairs in sequence. The method requires that srcArrayBundle and dstArrayBundle reference an identical number of ESMF_Array objects.
The effect of this method on ArrayBundles that contain aliased members is undefined.

PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the `factorList` and `factorIndexList` arguments. Providing `factorList` and `factorIndexList` arguments with `size(factorList) = (/0/)` and `size(factorIndexList) = (/2,0/)` or `(/4,0/)` indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without `factorList` and `factorIndexList` arguments.

See the description of method `ESMF_ArraySMMStore()` for the definition of the Array based operation.

The routine returns an `ESMF_RouteHandle` that can be used to call `ESMF_ArrayBundleSMM()` on any pair of ArrayBundles that are weakly congruent and typekind conform with the Arrays contained in `srcArrayBundle` and `dstArrayBundle`. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same `routehandle` can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

**srcArrayBundle** `ESMF_ArrayBundle` with source data.

**dstArrayBundle** `ESMF_ArrayBundle` with destination data. The data in these Arrays may be destroyed by this call.

**routehandle** Handle to the precomputed Route.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

---

### 26.5.26 ESMF_ArrayBundleWrite - Write the Arrays into a file

**INTERFACE:**

```fortran
subroutine ESMF_ArrayBundleWrite(arraybundle, file, &
   singleFile, overwrite, status, timeslice, iofmt, rc)
```

**ARGUMENTS:**

<table>
<thead>
<tr>
<th>Type</th>
<th>Intent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type(ESMF_ArrayBundle),</td>
<td>intent(in)</td>
<td>:: arraybundle</td>
</tr>
<tr>
<td>character(*)</td>
<td>intent(in)</td>
<td>:: file</td>
</tr>
<tr>
<td>logical</td>
<td>intent(in),</td>
<td>optional :: singleFile</td>
</tr>
<tr>
<td>logical</td>
<td>intent(in),</td>
<td>optional :: overwrite</td>
</tr>
<tr>
<td>type(ESMF_FileStatus_Flag)</td>
<td>intent(in),</td>
<td>optional :: status</td>
</tr>
<tr>
<td>integer</td>
<td>intent(in),</td>
<td>optional :: timeslice</td>
</tr>
<tr>
<td>type(ESMF_IOFmt_Flag)</td>
<td>intent(in),</td>
<td>optional :: iofmt</td>
</tr>
<tr>
<td>integer</td>
<td>intent(out),</td>
<td>optional :: rc</td>
</tr>
</tbody>
</table>

**DESCRIPTION:**
Write the Arrays into a file. For this API to be functional, the environment variable `ESMF_PIO` should be set to "internal" when the ESMF library is built. Please see the section on Data I/O.

Limitations:

- Only 1 DE per PET supported.
- Not supported in `ESMF_COMM=mpiuni` mode.

The arguments are:

- `arraybundle` An ESMF_ArrayBundle object.
- `file` The name of the output file to which array bundle data is written.
- `singleFile` A logical flag, the default is `.true., i.e., all arrays in the bundle are written in one single file. If `.false., each array will be written in separate files; these files are numbered with the name based on the argument "file". That is, a set of files are named: `[file_name]001, [file_name]002, [file_name]003,...`
- `overwrite` A logical flag, the default is `.false., i.e., existing field data may *not* be overwritten. If `.true., the overwrite behavior depends on the value of `iofmt` as shown below:
  - `iofmt = ESMF_IOFMT_BIN`: All data in the file will be overwritten with each field’s data.
  - `iofmt = ESMF_IOFMT_NETCDF`: Only the data corresponding to each field’s name will be overwritten. If the `timeslice` option is given, only data for the given timeslice may be overwritten. Note that it is always an error to attempt to overwrite a NetCDF variable with data which has a different shape.
- `status` The file status. Please see Section 50.19 for the list of options. If not present, defaults to `ESMF_FILESTATUS_UNKNOWN`.
- `timeslice` Some IO formats (e.g. NetCDF) support the output of data in form of time slices. The `timeslice` argument provides access to this capability. `timeslice` must be positive. The behavior of this option may depend on the setting of the `overwrite` flag:
  - `overwrite = .false.:` If the timeslice value is less than the maximum time already in the file, the write will fail.
  - `overwrite = .true.:` Any positive timeslice value is valid.
  By default, i.e. by omitting the `timeslice` argument, no provisions for time slicing are made in the output file, however, if the file already contains a time axis for the variable, a timeslice one greater than the maximum will be written.
- `iofmt` The IO format. Please see Section 50.26 for the list of options. If not present, defaults to `ESMF_IOFMT_NETCDF`.
- `rc` Return code; equals `ESMF_SUCCESS` if there are no errors.

## 27 Array Class

### 27.1 Description

The Array class is an alternative to the Field class for representing distributed, structured data. Unlike Fields, which are built to carry grid coordinate information, Arrays can only carry information about the *indices* associated with grid cells. Since they do not have coordinate information, Arrays cannot be used to calculate interpolation weights. However, if the user can supply interpolation weights, the Array sparse matrix multiply operation can be used to apply...
the weights and transfer data to the new grid. Arrays can also perform redistribution, scatter, and gather communication operations.

Like Fields, Arrays can be added to a State and used in inter-Component data communications. Arrays can also be grouped together into ArrayBundles so that collective operations can be performed on the whole group. One motivation for this is convenience; another is the ability to schedule optimized, collective data transfers.

From a technical standpoint, the ESMF Array class is an index space based, distributed data storage class. It provides DE-local memory allocations within DE-centric index regions and defines the relationship to the index space described by the ESMF DistGrid. The Array class offers common communication patterns within the index space formalism. As part of the ESMF index space layer, Array has close relationship to the DistGrid and DELayout classes.

27.2 Use and Examples

An ESMF_Array is a distributed object that must exist on all PETs of the current context. Each PET-local instance of an Array object contains memory allocations for all PET-local DEs. There may be 0, 1, or more DEs per PET and the number of DEs per PET can differ between PETs for the same Array object. Memory allocations may be provided for each PET by the user during Array creation or can be allocated as part of the Array create call. Many of the concepts of the proposed ESMF_Array class are illustrated by the following examples.

27.2.1 Array from native Fortran array with 1 DE per PET

The create call of the ESMF_Array class has been overloaded extensively to facilitate the need for generality while keeping simple cases simple. The following program demonstrates one of the simpler cases, where existing local Fortran arrays are to be used to provide the PET-local memory allocations for the Array object.

```fortran
program ESMF_ArrayFarrayEx
  include "ESMF.h"

  use ESMF
  use ESMF_TestMod

  implicit none

end program ESMF_ArrayFarrayEx
```

The Fortran language provides a variety of ways to define and allocate an array. Actual Fortran array objects must either be explicit-shape or deferred-shape. In the first case the memory allocation and deallocation is automatic from the user’s perspective and the details of the allocation (static or dynamic, heap or stack) are left to the compiler. (Compiler flags may be used to control some of the details). In the second case, i.e. for deferred-shape actual objects, the array definition must include the pointer or allocatable attribute and it is the user’s responsibility to allocate memory. While it is also the user’s responsibility to deallocate memory for arrays with the pointer attribute the compiler will automatically deallocate allocatable arrays under certain circumstances defined by the Fortran standard.

The ESMF_ArrayCreate() interface has been written to accept native Fortran arrays of any flavor as a means to allow user-controlled memory management. The Array create call will check on each PET if sufficient memory has been provided by the specified Fortran arrays and will indicate an error if a problem is detected. However, the Array create call cannot validate the lifetime of the provided memory allocations. If, for instance, an Array object was created in a subroutine from an automatic explicit-shape array or an allocatable array, the memory allocations referenced by the Array object will be automatically deallocated on return from the subroutine unless provisions are made by the application writer to prevent such behavior. The Array object cannot control when memory that has been provided by
the user during Array creation becomes deallocated, however, the Array will indicate an error if its memory references have been invalidated.

The easiest, portable way to provide safe native Fortran memory allocations to Array create is to use arrays with the pointer attribute. Memory allocated for an array pointer will not be deallocated automatically. However, in this case the possibility of memory leaks becomes an issue of concern. The deallocation of memory provided to an Array in form of a native Fortran allocation will remain the users responsibility.

None of the concerns discussed above are an issue in this example where the native Fortran array \texttt{farray} is defined in the main program. All different types of array memory allocation are demonstrated in this example. First \texttt{farrayE} is defined as a 2D explicit-shape array on each PET which will automatically provide memory for $10 \times 10$ elements.

\begin{verbatim}
! local variables
real(ESMF_KIND_R8) :: farrayE(10,10) ! explicit shape Fortran array
\end{verbatim}

Then an allocatable array \texttt{farrayA} is declared which will be used to show user-controlled dynamic memory allocation.

\begin{verbatim}
real(ESMF_KIND_R8), allocatable :: farrayA(:, :) ! allocatable Fortran array
\end{verbatim}

Finally an array with pointer attribute \texttt{farrayP} is declared, also used for user-controlled dynamic memory allocation.

\begin{verbatim}
real(ESMF_KIND_R8), pointer :: farrayP(:, :) ! Fortran array pointer
\end{verbatim}

A matching array pointer must also be available to gain access to the arrays held by an Array object.

\begin{verbatim}
real(ESMF_KIND_R8), pointer :: farrayPtr(:, :) ! matching Fortran array ptr
type(ESMF_DistGrid) :: distgrid ! DistGrid object
type(ESMF_Array) :: array ! Array object
integer :: rc
\end{verbatim}

\begin{verbatim}
call ESMF_Initialize(defaultlogfilename="ArrayFarrayEx.Log", &
logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
\end{verbatim}

On each PET \texttt{farrayE} can be accessed directly to initialize the entire PET-local array.

\begin{verbatim}
farrayE = 12.45d0 ! initialize to some value
\end{verbatim}

In order to create an Array object a DistGrid must first be created that describes the total index space and how it is decomposed and distributed. In the simplest case only the \texttt{minIndex} and \texttt{maxIndex} of the total space must be provided.

\begin{verbatim}
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/40,10/), rc=rc)
\end{verbatim}
This example is assumed to run on 4 PETs. The default 2D decomposition will then be into 4 x 1 DEs as to ensure 1 DE per PET.

Now the Array object can be created using the `farrayE` and the DistGrid just created.

```fortran
array = ESMF_ArrayCreate(farray=farrayE, distgrid=distgrid, &
indexflag=ESMF_INDEX_DELOCAL, rc=rc)
```

The 40 x 10 index space defined by the `minIndex` and `maxIndex` arguments paired with the default decomposition will result in the following distributed Array.

```
+---------------------------> 2nd dimension
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
|                        |
```

Providing `farrayE` during Array creation does not change anything about the actual `farrayE` object. This means that each PET can use its local `farrayE` directly to access the memory referenced by the Array object.

```fortran
print *, farrayE
```

Another way of accessing the memory associated with an Array object is to use `ArrayGet()` to obtain a Fortran pointer that references the PET-local array.

```fortran
call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc)
```

```fortran
print *, farrayPtr
```
Finally the Array object must be destroyed. The PET-local memory of the \texttt{farrayE}s will remain in user control and will not be altered by \texttt{ArrayDestroy()}.  

```fortran
  call ESMF_ArrayDestroy(array, rc=rc)
```

Since the memory allocation for each \texttt{farrayE} is automatic there is nothing more to do.

The interaction between \texttt{farrayE} and the Array class is representative also for the two other cases \texttt{farrayA} and \texttt{farrayP}. The only difference is in the handling of memory allocations.

```fortran
allocate(farrayA(10,10)) ! user controlled allocation
farrayA = 23.67d0 ! initialize to some value
array = ESMF_ArrayCreate(farray=farrayA, distgrid=distgrid, &
                         indexflag=ESMF_INDEX_DELOCAL, rc=rc)

print *, farrayA ! print PET-local farrayA directly
call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc) ! obtain array pointer
print *, farrayPtr ! print PET-local piece of Array through pointer
call ESMF_ArrayDestroy(array, rc=rc) ! destroy the Array
deallocate(farrayA) ! user controlled de-allocation
```

The \texttt{farrayP} case is identical.

```fortran
allocate(farrayP(10,10)) ! user controlled allocation
farrayP = 56.81d0 ! initialize to some value
array = ESMF_ArrayCreate(farray=farrayP, distgrid=distgrid, &
                         indexflag=ESMF_INDEX_DELOCAL, rc=rc)

print *, farrayP ! print PET-local farrayA directly
call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc) ! obtain array pointer
print *, farrayPtr ! print PET-local piece of Array through pointer
call ESMF_ArrayDestroy(array, rc=rc) ! destroy the Array
deallocate(farrayP) ! user controlled de-allocation
```

To wrap things up the DistGrid object is destroyed and ESMF can be finalized.

```fortran
  call ESMF_DistGridDestroy(distgrid, rc=rc) ! destroy the DistGrid
  call ESMF_Finalize(rc=rc)
end program
```
27.2.2 Array from native Fortran array with extra elements for halo or padding

The example of the previous section showed how easy it is to create an Array object from existing PET-local Fortran arrays. The example did, however, not define any halo elements around the DE-local regions. The following code demonstrates how an Array object with space for a halo can be set up.

```fortran
program ESMF_ArrayFarrayHaloEx

! local variables
real(ESMF_KIND_R8), allocatable :: farrayA(:,,:) ! allocatable Fortran array
real(ESMF_KIND_R8), pointer :: farrayPtr(:,,:) ! matching Fortran array ptr
type(ESMF_DistGrid) :: distgrid ! DistGrid object
type(ESMF_Array) :: array ! Array object
integer :: rc, i, j
real :: localSum

allocate(farrayA(14,14)) ! Fortran array with halo: 14 = 10 + 2 * 2

call ESMF_Initilize(defaultlogfile="ArrayFarrayHaloEx.Log", &
                    logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
```

The Array is to cover the exact same index space as in the previous example. Furthermore decomposition and distribution are also kept the same. Hence the same DistGrid object will be created and it is expected to execute this example with 4 PETs.

```fortran
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/40,10/), rc=rc)
```

This DistGrid describes a 40 x 10 index space that will be decomposed into 4 DEs when executed on 4 PETs, associating 1 DE per PET. Each DE-local exclusive region contains 10 x 10 elements. The DistGrid also stores and provides information about the relationship between DEs in index space, however, DistGrid does not contain information about halos. Arrays contain halo information and it is possible to create multiple Arrays covering the same index space with identical decomposition and distribution using the same DistGrid object, while defining different, Array-specific halo regions.

The extra memory required to cover the halo in the Array object must be taken into account when allocating the PET-local farrayA arrays. For a halo of 2 elements in each direction the following allocation will suffice.

```fortran
allocate(farrayA(14,14)) ! Fortran array with halo: 14 = 10 + 2 * 2
```
The \texttt{farrayA} can now be used to create an Array object with enough space for a two element halo in each direction. The Array creation method checks for each PET that the local Fortran array can accommodate the requested regions.

The default behavior of \texttt{ArrayCreate()} is to center the exclusive region within the total region. Consequently the following call will provide the 2 extra elements on each side of the exclusive 10 x 10 region without having to specify any additional arguments.

\begin{verbatim}
array = ESMF_ArrayCreate(farray=farrayA, distgrid=distgrid, &
indexflag=ESMF_INDEX_DELOCAL, rc=rc)
\end{verbatim}

The exclusive Array region on each PET can be accessed through a suitable Fortran array pointer. See section \ref{section:27.2.6} for more details on Array regions.

\begin{verbatim}
call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc)
\end{verbatim}

Following Array bounds convention, which by default puts the beginning of the exclusive region at (1, 1, ...), the following loop will add up the values of the local exclusive region for each DE, regardless of how the bounds were chosen for the original PET-local \texttt{farrayA} arrays.

\begin{verbatim}
localSum = 0.
do j=1, 10
  do i=1, 10
    localSum = localSum + farrayPtr(i, j)
  enddo
enddo
\end{verbatim}

Elements with \texttt{i} or \texttt{j} in the [-1,0] or [11,12] ranges are located outside the exclusive region and may be used to define extra computational points or halo operations.

Cleanup and shut down ESMF:

\begin{verbatim}
call ESMF_ArrayDestroy(array, rc=rc)
deallocate(farrayA)
call ESMF_DistGridDestroy(distgrid, rc=rc)
call ESMF_Finalize(rc=rc)
\end{verbatim}

\textbf{27.2.3 Array from ESMF\_LocalArray}

Alternative to the direct usage of Fortran arrays during Array creation it is also possible to first create an \texttt{ESMF\_LocalArray} and create the Array from it. While this may seem more burdensome for the 1 DE per PET
cases discussed in the previous sections it allows a straightforward generalization to the multiple DE per PET case. The following example first recaptures the previous example using an ESMF_LocalArray and then expands to the multiple DE per PET case.

```fortran
program ESMF_ArrayLarrayEx
#include "ESMF.h"

use ESMF
use ESMF_TestMod

implicit none

The current ESMF_LocalArray interface requires Fortran arrays to be defined with pointer attribute.

! local variables
real(ESMF_KIND_R8), pointer :: farrayP(:,,:) ! Fortran array pointer
real(ESMF_KIND_R8), pointer :: farrayPtr(:,,:) ! matching Fortran array ptr
type(ESMF_LocalArray) :: larray ! ESMF_LocalArray object
type(ESMF_LocalArray) :: larrayRef ! ESMF_LocalArray object
type(ESMF_DistGrid) :: distgrid ! DistGrid object
type(ESMF_Array) :: array ! Array object
integer :: rc, i, j, de
real :: localSum
type(ESMF_LocalArray), allocatable :: larrayList(:) ! LocalArray object list
type(ESMF_LocalArray), allocatable :: larrayRefList(:) ! LocalArray object list
type(ESMF_VM):: vm
integer:: localPet, petCount

call ESMF_Initialize(vm=vm, defaultlogfilename="ArrayLarrayEx.Log", &
   logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_VMGet(vm, localPet=localPet, petCount=petCount, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
if (petCount /= 4) then
   finalrc = ESMF_FAILURE
   goto 10
endif

DistGrid and array allocation remains unchanged.

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/40,10/), rc=rc)
allocate(farrayP(14,14)) ! allocate Fortran array on each PET with halo
```

436
Now instead of directly creating an Array object using the PET-local farrayPs an ESMF_LocalArray object will be created on each PET.

\[ larray = \text{ESMF\_LocalArrayCreate}(farrayP, & \text{datacopyflag=ESMF\_DATACOPY\_REFERENCE, rc=rc}) \]

The Array object can now be created from \( larray \). The Array creation method checks for each PET that the LocalArray can accommodate the requested regions.

\[ array = \text{ESMF\_ArrayCreate}(\text{localarrayList}=\{larray\}, \text{distgrid=distgrid, rc=rc}) \]

Once created there is no difference in how the Array object can be used. The exclusive Array region on each PET can be accessed through a suitable Fortran array pointer as before.

\[ \text{call ESMF\_ArrayGet(array, farrayPtr=farrayPtr, rc=rc)} \]

Alternatively it is also possible (independent of how the Array object was created) to obtain the reference to the array allocation held by Array in form of an ESMF_LocalArray object. The farrayPtr can then be extracted using LocalArray methods.

\[ \text{call ESMF\_ArrayGet(array, localarray=larrayRef, rc=rc)} \]
\[ \text{call ESMF\_LocalArrayGet(larrayRef, farrayPtr, rc=rc)} \]

Either way the farrayPtr reference can be used now to add up the values of the local exclusive region for each DE. The following loop works regardless of how the bounds were chosen for the original PET-local farrayP arrays and consequently the PET-local larray objects.

\[
\text{localSum} = 0.
\text{do j=1, 10}
\text{do i=1, 10}
\text{localSum} = \text{localSum} + \text{farrayPtr}(i, j)
\text{enddo}
\text{enddo}
\text{print *, "localSum=", localSum}
\]

Cleanup.

\[ \text{call ESMF\_ArrayDestroy(array, rc=rc)} \]
\[ \text{call ESMF\_LocalArrayDestroy(larray, rc=rc)} \]
\[ \text{deallocate(farrayP)} \quad ! \text{use the pointer that was used in allocate statement} \]
\[ \text{call ESMF\_DistGridDestroy(distgrid, rc=rc)} \]
While the usage of LocalArrays is unnecessarily cumbersome for 1 DE per PET Arrays, it provides a straight forward path for extending the interfaces to multiple DEs per PET.

In the following example a 8 x 8 index space will be decomposed into 2 x 4 = 8 DEs. The situation is captured by the following DistGrid object.

```
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/8,8/), &
regDecomp=(/2,4/), rc=rc)
```

The `distgrid` object created in this manner will contain 8 DEs no matter how many PETs are available during execution. Assuming an execution on 4 PETs will result in the following distribution of the decomposition.

```
+---------------------------------------> 2nd dimension
| (1,1)
+-----------+-----------+-----------+-----------+
| DE0, PET0 | DE2, PET1 | DE4, PET2 | DE6, PET3 |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
+-----------+-----------+-----------+-----------+
| DE1, PET0 | DE3, PET1 | DE5, PET2 | DE7, PET3 |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
| * * | * * | * * | * * |
+-----------+-----------+-----------+-----------+
| (8,8) |
```

Obviously each PET is associated with 2 DEs. Each PET must allocate enough space for all its DEs. This is done by allocating as many DE-local arrays as there are DEs on the PET. The reference to these array allocations is passed into ArrayCreate via a LocalArray list argument that holds as many elements as there are DEs on the PET. Here each PET must allocate for two DEs.

```
allocate(larrayList(2)) ! 2 DEs per PET
allocate(farrayP(4, 2)) ! without halo each DE is of size 4 x 2
farrayP = 123.456d0
larrayList(1) = ESMF_LocalArrayCreate(farrayP, &
datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc) !1st DE
allocate(farrayP(4, 2)) ! without halo each DE is of size 4 x 2
farrayP = 456.789d0
larrayList(2) = ESMF_LocalArrayCreate(farrayP, &
```
Notice that it is perfectly fine to re-use `farrayP` for all allocations of DE-local Fortran arrays. The allocated memory can be deallocated at the end using the array pointer contained in the `larrayList`.

With this information an `Array` object can be created. The `distgrid` object indicates 2 DEs for each PET and `ArrayCreate()` expects to find two `LocalArray` elements in `larrayList`.

```plaintext
array = ESMF_ArrayCreate(localarrayList=larrayList, distgrid=distgrid, rc=rc)
```

Usage of a `LocalArray` list is the only way to provide a list of variable length of Fortran array allocations to `ArrayCreate()` for each PET. The `array` object created by the above call is an ESMF distributed object. As such it must follow the ESMF convention that requires that the call to `ESMF_ArrayCreate()` must be issued in unison by all PETs of the current context. Each PET only calls `ArrayCreate()` once, even if there are multiple DEs per PET.

The `ArrayGet()` method provides access to the list of `LocalArrays` on each PET.

```plaintext
allocate(larrayRefList(2))
call ESMF_ArrayGet(array, localarrayList=larrayRefList, rc=rc)
```

Finally, access to the actual Fortran pointers is done on a per DE basis. Generally each PET will loop over its DEs.

```plaintext
do de=1, 2
   call ESMF_LocalArrayGet(larrayRefList(de), farrayPtr, rc=rc)
   localSum = 0.
   do j=1, 2
      do i=1, 4
         localSum = localSum + farrayPtr(i, j)
      enddo
   enddo
   print *, "localSum=", localSum
endo
do de=1, 2
   call ESMF_LocalArrayGet(larrayList(de), farrayPtr, rc=rc)
   deallocate(farrayPtr)
call ESMF_LocalArrayDestroy(larrayList(de), rc=rc)
```

Note: If the VM associates multiple PEs with a PET the application writer may decide to use OpenMP loop parallelization on the `de` loop.

Cleanup requires that the PET-local deallocations are done before the pointers to the actual Fortran arrays are lost. Notice that `larrayList` is used to obtain the pointers used in the `deallocate` statement. Pointers obtained from the `larrayRefList`, while pointing to the same data, cannot be used to deallocated the array allocations!
enddo
deallocate(larrayList)
deallocate(larrayRefList)
call ESMF_ArrayDestroy(array, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_DistGridDestroy(distgrid, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

With that ESMF can be shut down cleanly.

call ESMF_Finalize(rc=rc)

end program

27.2.4 Create Array with automatic memory allocation

In the examples of the previous sections the user provided memory allocations for each of the DE-local regions for an Array object. The user was able to use any of the Fortran methods to allocate memory, or go through the ESMF_LocalArray interfaces to obtain memory allocations before passing them into ArrayCreate(). Alternatively ESMF offers methods that handle Array memory allocations inside the library.

As before, to create an ESMF_Array object an ESMF_DistGrid must be created. The DistGrid object holds information about the entire index space and how it is decomposed into DE-local exclusive regions. The following line of code creates a DistGrid for a 5x5 global index space that is decomposed into 2 x 3 = 6 DEs.

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
     regDecomp=(/2,3/), rc=rc)

The following is a representation of the index space and its decompositon into DEs. Each asterix (*) represents a single element.
Besides the DistGrid it is the *type, kind and rank* information, "tkr" for short, that is required to create an Array object. It turns out that the rank of the Array object is fully determined by the DistGrid and other (optional) arguments passed into ArrayCreate(), so that explicit specification of the Array rank is redundant.

The simplest way to supply the type and kind information of the Array is directly through the *typekind* argument. Here a double precision Array is created on the previously created DistGrid. Since no other arguments are specified that could alter the rank of the Array it becomes equal to the dimCount of the DistGrid, i.e a 2D Array is created on top of the DistGrid.

```ruby
array = ESMF_ArrayCreate(typekind=ESMF_TYPEKIND_R8, distgrid=distgrid, rc=rc)
```

The different methods on how an Array object is created have no effect on the use of ESMF_ArrayDestroy().

```ruby
call ESMF_ArrayDestroy(array, rc=rc)
```

Alternatively the same Array can be created specifying the "tkr" information in form of an ArraySpec variable. The ArraySpec explicitly contains the Array rank and thus results in an overspecification on the ArrayCreate() interface. ESMF checks all input information for consistency and returns appropriate error codes in case any inconsistencies are found.

```ruby
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)
array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, rc=rc)
```

The Array object created by the above call is an ESMF distributed object. As such it must follow the ESMF convention that requires that the call to ESMF_ArrayCreate() must be issued in unison by all PETs of the current context.

### 27.2.5 Native language memory access

There are two different methods by which the user can access the data held inside an ESMF Array object. The first method provides direct access to a native language array object. Specifically, the *farrayPtr* argument returned by ESMF_ArrayGet() is a Fortran array pointer that can be used to access the PET-local data inside the Array object.

Many applications work in the 1 DE per PET mode, with exactly one DE on every PET. Accessing the Array memory on each PET for this situation is especially simple as is shown in section 27.2.1. However, the Array class is not restricted to the special 1 DE per PET case, but supports multiple separate memory allocations on each PET. The
number of such PET-local allocations is given by the localDeCount, i.e. there is one memory allocation for every 
DE that is associated with the local PET.

Access to a specific local memory allocation of an Array object is still accomplished by returning the farrayPtr 
argument. However, for localDeCount > 1 the formally optional localDe argument to ESMF_ArrayGet() 
turns into a practically required argument. While in general the localDe in ESMF is simply a local index variable 
that enumerates the DEs that are associated with the local PET (e.g. see section 47.5.1), the bounds of this index 
variable are strictly defined as [0,...,localDeCount-1] when it is used as an input argument. The following 
code demonstrates this.

First query the Array for localDeCount. This number may be different on each PET and indicates how many DEs 
are mapped against the local PET.

call ESMF_ArrayGet(array, localDeCount=localDeCount, rc=rc)

Looping the localDe index variable from 0 to localDeCount-1 allows access to each of the local memory 
allocations of the Array object:

do localDe=0, localDeCount-1
   call ESMF_ArrayGet(array, farrayPtr=myFarray, localDe=localDe, rc=rc)

   ! use myFarray to access local DE data
enddo

The second method to access the memory allocations in an Array object is to go through the ESMF LocalArray 
object. To this end the Array is queried for a list of PET-local LocalArray objects. The LocalArray objects in the 
list correspond to the DEs on the local PET. Here the localDe argument is solely a user level index variable, and in 
principle the lower bound can be chosen freely. However, for better alignment with the previous case (where localDe 
served as an input argument to an ESMF method) the following example again fixes the lower bound at zero.

allocate(larrayList(0:localDeCount-1))
call ESMF_ArrayGet(array, localarrayList=larrayList, rc=rc)

do localDe=0, localDeCount-1
   call ESMF_LocalArrayGet(larrayList(localDe), myFarray, &
   datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)

   ! use myFarray to access local DE data
enddo

See section 27.2.3 for more on LocalArray usage in Array. In most cases memory access through a LocalArray list is 
less convenient than the direct farrayPtr method because it adds an extra object level between the ESMF Array 
and the native language array.
27.2.6 Regions and default bounds

Each ESMF_Array object is decomposed into DEs as specified by the associated ESMF_DistGrid object. Each piece of this decomposition, i.e. each DE, holds a chunk of the Array data in its own local piece of memory. The details of the Array decomposition are described in the following paragraphs.

At the center of the Array decomposition is the ESMF_DistGrid class. The DistGrid object specified during Array creation contains three essential pieces of information:

- The extent and topology of the global domain covered by the Array object in terms of indexed elements. The total extent may be a composition of smaller logically rectangular (LR) domain pieces called tiles.

- The decomposition of the entire domain into "element exclusive" DE-local LR chunks. Element exclusive means that there is no element overlap between DE-local chunks. This, however, does not exclude degeneracies on edge boundaries for certain topologies (e.g. bipolar).

- The layout of DEs over the available PETs and thus the distribution of the Array data.

Each element of an Array is associated with a single DE. The union of elements associated with a DE, as defined by the DistGrid above, corresponds to a LR chunk of index space, called the exclusive region of the DE.

There is a hierarchy of four regions that can be identified for each DE in an Array object. Their definition and relationship to each other is as follows:

- **Interior Region**: Region that only contains local elements that are not mapped into the halo of any other DE. The shape and size of this region for a particular DE depends non-locally on the halos defined by other DEs and may change during computation as halo operations are precomputed and released. Knowledge of the interior elements may be used to improve performance by overlapping communications with ongoing computation for a DE.

- **Exclusive Region**: Elements for which a DE claims exclusive ownership. Practically this means that the DE will be the sole source for these elements in halo and reduce operations. There are exceptions to this in some topologies. The exclusive region includes all elements of the interior region.

- **Computational Region**: Region that can be set arbitrarily within the bounds of the total region (defined next). The typical use of the computation region is to define bounds that only include elements that are updated by a DE-local computation kernel. The computational region does not need to include all exclusive elements and it may also contain elements that lie outside the exclusive region.

- **Total (Memory) Region**: Total of all DE-locally allocated elements. The size and shape of the total memory region must accommodate the union of exclusive and computational region but may contain additional elements. Elements outside the exclusive region may overlap with the exclusive region of another DE which makes them potential receivers for Array halo operations. Elements outside the exclusive region that do not overlap with the exclusive region of another DE can be used to set boundary conditions and/or serve as extra memory padding.

```
+-totalLBound(:)--------------------------+
  \ <--- totalLWidth(:)
  \+-computationalLBound(:)--------------+
    \ <--- computationalLWidth(:)
    \+-exclusiveLBound(:)--------------+
```

443
With the following definitions:

\[
\begin{align*}
\text{computationalLWidth}(:) &= \text{exclusiveLBound}(:) - \text{computationalLBound}(:) \\
\text{computationalUWidth}(:) &= \text{computationalUBound}(:) - \text{exclusiveUBound}(:)
\end{align*}
\]

and

\[
\begin{align*}
\text{totalLWidth}(:) &= \text{exclusiveLBound}(:) - \text{totalLBound}(:) \\
\text{totalUWidth}(:) &= \text{totalUBound}(:) - \text{exclusiveUBound}(:)
\end{align*}
\]

The *exclusive region* is determined during Array creation by the DistGrid argument. Optional arguments may be used to specify the *computational region* when the Array is created, by default it will be set equal to the exclusive region. The *total region*, i.e. the actual memory allocation for each DE, is also determined during Array creation. When creating the Array object from existing Fortran arrays the total region is set equal to the memory provided by the Fortran arrays. Otherwise the default is to allocate as much memory as is needed to accommodate the union of the DE-local exclusive and computational region. Finally it is also possible to use optional arguments to the ArrayCreate() call to specify the total region of the object explicitly.

The ESMF_ArrayCreate() call checks that the input parameters are consistent and will result in an Array that fulfills all of the above mentioned requirements for its DE-local regions.

Once an Array object has been created the exclusive and total regions are fixed. The computational region, however, may be adjusted within the limits of the total region using the ArraySet() call.

The *interior region* is very different from the other regions in that it cannot be specified. The *interior region* for each DE is a consequence of the choices made for the other regions collectively across all DEs into which an Array object is decomposed. An Array object can be queried for its DE-local *interior regions* as to offer additional information to the user necessary to write more efficient code.
By default the bounds of each DE-local total region are defined as to put the start of the DE-local exclusive region at the "origin" of the local index space, i.e. at \((1, 1, \ldots, 1)\). With that definition the following loop will access each element of the DE-local memory segment for each PET-local DE of the Array object used in the previous sections and print its content.

    do localDe=0, localDeCount-1
        call ESMF_LocalArrayGet(larrayList(localDe), myFarray, &
        datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
        do i=1, size(myFarray, 1)
            do j=1, size(myFarray, 2)
                print *, "localPET=", localPet, " localDE=", &
                localDe, ": array("i","","j")="myFarray(i,j)
            enddo
        enddo
    enddo

27.2.7 Array bounds

The loop over Array elements at the end of the last section only works correctly because of the default definition of the computational and total regions used in the example. In general, without such specific knowledge about an Array object, it is necessary to use a more formal approach to access its regions with DE-local indices.

The DE-local exclusive region takes a central role in the definition of Array bounds. Even as the computational region may adjust during the course of execution the exclusive region remains unchanged. The exclusive region provides a unique reference frame for the index space of all Arrays associated with the same DistGrid.

There is a choice between two indexing options that needs to be made during Array creation. By default each DE-local exclusive region starts at \((1, 1, \ldots, 1)\). However, for some computational kernels it may be more convenient to choose the index bounds of the DE-local exclusive regions to match the index space coordinates as they are defined in the corresponding DistGrid object. The second option is only available if the DistGrid object does not contain any non-contiguous decompositions (such as cyclically decomposed dimensions).

The following example code demonstrates the safe way of dereferencing the DE-local exclusive regions of the previously created array object.

    allocate(exclusiveUBound(2, 0:localDeCount-1)) ! dimCount=2
    allocate(exclusiveLBound(2, 0:localDeCount-1)) ! dimCount=2
    call ESMF_ArrayGet(array, indexflag=indexflag, &
    exclusiveLBound=exclusiveLBound, exclusiveUBound=exclusiveUBound, rc=rc)
    if (indexflag == ESMF_INDEX_DELOCAL) then
        ! this is the default
        ! print *, "DE-local exclusive regions start at (1,1)"
        do localDe=0, localDeCount-1
            call ESMF_LocalArrayGet(larrayList(localDe), myFarray, &
            datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
            do i=1, exclusiveUBound(1, localDe)
                do j=1, exclusiveUBound(2, localDe)
                    ! print *, "DE-local exclusive region for localDE=", localDe, &
                    ! ": array("i","","j")="myFarray(i,j)
                enddo
            enddo
        enddo
    else if (indexflag == ESMF_INDEX_GLOBAL) then
        ! only if set during ESMF_ArrayCreate()
!     print *, "DE-local exclusive regions of this Array have global bounds"
do localDe=0, localDeCount-1
    call ESMF_LocalArrayGet (larrayList(localDe), myFarray, &
        datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
    do i=exclusiveLBound(1, localDe), exclusiveUBound(1, localDe)
        do j=exclusiveLBound(2, localDe), exclusiveUBound(2, localDe)
!         print *, "DE-local exclusive region for localDE=" , localDe, &
!         ": array(",i","," ,j",")=" , myFarray(i,j)
        enddo
    enddo
enddo
endif

call ESMF_ArrayDestroy (array, rc=rc) ! destroy the array object

Obviously the second branch of this simple code will work for either case, however, if a complex computational kernel
was written assuming ESMF_INDEX_DELOCAL type bounds the second branch would simply be used to indicate the
problem and bail out.

The advantage of the ESMF_INDEX_GLOBAL index option is that the Array bounds directly contain information on
where the DE-local Array piece is located in a global index space sense. When the ESMF_INDEX_DELOCAL option
is used the correspondence between local and global index space must be made by querying the associated DistGrid
for the DE-local indexList arguments.

27.2.8 Computational region and extra elements for halo or padding

In the previous examples the computational region of array was chosen by default to be identical to the exclusive re-
region defined by the DistGrid argument during Array creation. In the following the same arrayspec and distgrid
objects as before will be used to create an Array but now a larger computational region shall be defined around each
DE-local exclusive region. Furthermore, extra space will be defined around the computational region of each DE to
accommodate a halo and/or serve as memory padding.

In this example the indexflag argument is set to ESMF_INDEX_GLOBAL indicating that the bounds of the exclu-
sive region correspond to the index space coordinates as they are defined by the DistGrid object.

The same arrayspec and distgrid objects as before are used which also allows the reuse of the already allocated
larrayList variable.

array = ESMF_ArrayCreate (arrayspec=arrayspec, distgrid=distgrid, &
    computationalLWidth=(/0,3/), computationalUWidth=(/1,1/), &
    totalLWidth=(/1,4/), totalUWidth=(/3,1/), &
    indexflag=ESMF_INDEX_GLOBAL, rc=rc)

Obtain the larrayList on every PET.

allocate (localDeToDeMap(0:localDeCount-1))
call ESMF_ArrayGet (array, localarrayList=larrayList, &
    localDeToDeMap=localDeToDeMap, rc=rc)

The bounds of DE 1 for array are shown in the following diagram to illustrate the situation. Notice that the
totalLWidth and totalUWidth arguments in the ArrayCreate() call define the total region with respect to the
exclusive region given for each DE by the distgrid argument.

446
When working with this array it is possible for the computational kernel to overstep the exclusive region for both read/write access (computational region) and potentially read-only access into the total region outside of the computational region, if a halo operation provides valid entries for these elements.

The Array object can be queried for absolute bounds:

```fortran
allocate(computationalLBound(2, 0:localDeCount-1)) ! dimCount=2
allocate(computationalUBound(2, 0:localDeCount-1)) ! dimCount=2
allocate(totalLBound(2, 0:localDeCount-1)) ! dimCount=2
allocate(totalUBound(2, 0:localDeCount-1)) ! dimCount=2
call ESMF_ArrayGet(array, exclusiveLBound=exclusiveLBound, &
  exclusiveUBound=exclusiveUBound, &
  computationalLBound=computationalLBound, &
  computationalUBound=computationalUBound, &
  totalLBound=totalLBound, &
  totalUBound=totalUBound, rc=rc)
```

or for the relative widths:

```fortran
allocate(computationalLWidth(2, 0:localDeCount-1)) ! dimCount=2
allocate(computationalUWidth(2, 0:localDeCount-1)) ! dimCount=2
allocate(totalLWidth(2, 0:localDeCount-1)) ! dimCount=2
allocate(totalUWidth(2, 0:localDeCount-1)) ! dimCount=2
call ESMF_ArrayGet(array, computationalLWidth=computationalLWidth, &
  computationalUWidth=computationalUWidth, totalLWidth=totalLWidth, &
  totalUWidth=totalUWidth, rc=rc)
```

Either way the dereferencing of Array data is centered around the DE-local exclusive region:

```fortran
do localDe=0, localDeCount-1
  call ESMF_LocalArrayGet(larrayList(localDe), myFarray, &
    datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
  ! initialize the DE-local array
  myFarray = 0.1d0 * localDeToDeMap(localDe)
end do
```
27.2.9 Create 1D and 3D Arrays

All previous examples were written for the 2D case. There is, however, no restriction within the Array or DistGrid class that limits the dimensionality of Array objects beyond the language specific limitations (7D for Fortran).

In order to create an n-dimensional Array the rank indicated by both the arrayspec and the distgrid arguments specified during Array create must be equal to n. A 1D Array of double precision real data hence requires the following arrayspec.

```
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=1, rc=rc)
```

The index space covered by the Array and the decomposition description is provided to the Array create method by the distgrid argument. The index space in this example has 16 elements and covers the interval $[-10, 5]$. It is decomposed into as many DEs as there are PETs in the current context.

```
distgrid1D = ESMF_DistGridCreate(minIndex=(-10/), maxIndex=(/5/), &
    regDecomp=(/petCount/), rc=rc)
```
A 1D Array object with default regions can now be created.

```
array1D = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid1D, rc=rc)
```

The creation of a 3D Array proceeds analogous to the 1D case. The rank of the `arrayspec` must be changed to 3
```
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=3, rc=rc)
```

and an appropriate 3D DistGrid object must be created
```
distgrid3D = ESMF_DistGridCreate(minIndex=(/1,1,1/), &
maxIndex=(/16,16,16/), regDecomp=(/4,4,4/), rc=rc)
```

before an Array object can be created.

```
array3D = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid3D, rc=rc)
```

The `distgrid3D` object decomposes the 3-dimensional index space into $4 \times 4 \times 4 = 64$ DEs. These DEs are laid out across the computational resources (PETs) of the current component according to a default DELayout that is created during the DistGrid create call. Notice that in the index space proposal a DELayout does not have a sense of dimensionality. The DELayout function is simply to map DEs to PETs. The DistGrid maps chunks of index space against DEs and thus its rank is equal to the number of index space dimensions.

The previously defined DistGrid and the derived Array object decompose the index space along all three dimension. It is, however, not a requirement that the decomposition be along all dimensions. An Array with the same 3D index space could as well be decomposed along just one or along two of the dimensions. The following example shows how for the same index space only the last two dimensions are decomposed while the first Array dimension has full extent on all DEs.

```
call ESMF_ArrayDestroy(array3D, rc=rc)
call ESMF_DistGridDestroy(distgrid3D, rc=rc)
distgrid3D = ESMF_DistGridCreate(minIndex=(/1,1,1/), &
maxIndex=(/16,16,16/), regDecomp=(/1,4,4/), rc=rc)
array3D = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid3D, rc=rc)
```

### 27.2.10 Working with Arrays of different rank

Assume a computational kernel that involves the `array3D` object as it was created at the end of the previous section. Assume further that the kernel also involves a 2D Array on a 16x16 index space where each point (j,k) was interacting with each (i,j,k) column of the 3D Array. An efficient formulation would require that the decomposition of the 2D Array must match that of the 3D Array and further the DELayout be identical. The following code shows how this can be accomplished.

```
call ESMF_DistGridGet(distgrid3D, delayout=delayout, rc=rc) ! get DELayout
distgrid2D = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/16,16/), &
Now the following kernel is sure to work with array3D and array2D.

call ESMF_DELayoutGet(delayout, localDeCount=localDeCount, rc=rc)
allocate(larrayList1(0:localDeCount-1))
call ESMF_ArrayGet(array3D, localarrayList=larrayList1, rc=rc)
allocate(larrayList2(0:localDeCount-1))
call ESMF_ArrayGet(array2D, localarrayList=larrayList2, rc=rc)
do localDe=0, localDeCount-1
  call ESMF_LocalArrayGet(larrayList1(localDe), myFarray3D, &
  datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
  myFarray3D = 0.1d0 * localDe ! initialize
  call ESMF_LocalArrayGet(larrayList2(localDe), myFarray2D, &
  datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)
  myFarray2D = 0.5d0 * localDe ! initialize
  do k=1, 4
    do j=1, 4
      dummySum = 0.d0
      do i=1, 16
        dummySum = dummySum + myFarray3D(i,j,k) ! sum up the (j,k) column
      enddo
      dummySum = dummySum * myFarray2D(j,k) ! multiply with local 2D element
      !
    enddo
  enddo
enddo

27.2.11 Array and DistGrid rank – 2D+1 Arrays

Except for the special Array create interface that implements a copy from an existing Array object all other Array create interfaces require the specification of at least two arguments: farray and distgrid, larrayList and distgrid, or arrayspec and distgrid. In all these cases both required arguments contain a sense of dimensionality. The relationship between these two arguments deserves extra attention.

The first argument, farray, larrayList or arrayspec, determines the rank of the created Array object, i.e. the dimensionality of the actual data storage. The rank of a native language array, extracted from an Array object, is equal to the rank specified by either of these arguments. So is the rank that is returned by the ESMF_ArrayGet() call.

The rank specification contained in the distgrid argument, which is of type ESMF_DistGrid, on the other hand has no affect on the rank of the Array. The dimCount specified by the DistGrid object, which may be equal, greater or less than the Array rank, determines the dimensionality of the decomposition.

While there is no constraint between DistGrid dimCount and Array rank, there is an important relationship between the two, resulting in the concept of index space dimensionality. Array dimensions can be arbitrarily mapped against DistGrid dimension, rendering them decomposed dimensions. The index space dimensionality is equal to the number of decomposed Array dimensions.

Array dimensions that are not mapped to DistGrid dimensions are the undistributed dimensions of the Array. They are not part of the index space. The mapping is specified during ESMF_ArrayCreate() via the distgridToArrayMap argument. DistGrid dimensions that have not been associated with Array dimensions are replicating dimensions. The Array will be replicated across the DEs that lie along replication DistGrid dimensions.
Undistributed Array dimensions can be used to store multi-dimensional data for each Array index space element. One application of this is to store the components of a vector quantity in a single Array. The same 2D distgrid object as before will be used.

\[
\text{distgrid} = \text{ESMF_DistGridCreate}(\text{minIndex}=\langle 1,1 \rangle, \text{maxIndex}=\langle 5,5 \rangle, \&
\text{regDecomp}=\langle 2,3 \rangle, \text{rc}=\text{rc})
\]

The rank in the arrayspec argument, however, must change from 2 to 3 in order to provide for the extra Array dimension.

\[
\text{call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=3, rc=rc)}
\]

During Array creation with extra dimension(s) it is necessary to specify the bounds of these undistributed dimension(s). This requires two additional arguments, undistLBound and undistUBound, which are vectors in order to accommodate multiple undistributed dimensions. The other arguments remain unchanged and apply across all undistributed components.

\[
\text{array} = \text{ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, \&}
\text{totalLWidth}=\langle 0,1 \rangle, \text{totalUWidth}=\langle 0,1 \rangle, \&
\text{undistLBound}=\langle 1 \rangle, \text{undistUBound}=\langle 2 \rangle, \text{rc}=\text{rc})
\]

if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

This will create array with 2+1 dimensions. The 2D DistGrid is used to describe decomposition into DEs with 2 Array dimensions mapped to the DistGrid dimensions resulting in a 2D index space. The extra Array dimension provides storage for multi component user data within the Array object.

By default the distgrid dimensions are associated with the first Array dimensions in sequence. For the example above this means that the first 2 Array dimensions are decomposed according to the provided 2D DistGrid. The 3rd Array dimension does not have an associated DistGrid dimension, rendering it an undistributed Array dimension.

Native language access to an Array with undistributed dimensions is in principle the same as without extra dimensions.

\[
\text{call ESMF_ArrayGet(array, localDeCount=localDeCount, rc=rc)}
\]

allocate(larrayList(0:localDeCount-1))

\[
\text{call ESMF_ArrayGet(array, localarrayList=larrayList, rc=rc)}
\]

The following loop shows how a Fortran pointer to the DE-local data chunks can be obtained and used to set data values in the exclusive regions. The myFarray3D variable must be of rank 3 to match the Array rank of array. However, variables such as exclusiveUBound that store the information about the decomposition, remain to be allocated for the 2D index space.

\[
\text{call ESMF_ArrayGet(array, exclusiveLBound=exclusiveLBound, \&}
\text{exclusiveUBound=exclusiveUBound, rc=rc)}
\]

do localDe=0, localDeCount-1
\[
\text{call ESMF_LocalArrayGet(larrayList(localDe), myFarray3D, \&}
\text{datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)}
\]
myFarray3D = 0.0 ! initialize
myFarray3D(exclusiveLBound(1,localDe):exclusiveUBound(1,localDe), \&
exclusiveLBound(2,localDe):exclusiveUBound(2,localDe), &
1) = 5.1 ! dummy assignment
myFarray3D(exclusiveLBound(1,localDe):exclusiveUBound(1,localDe), &
exclusiveLBound(2,localDe):exclusiveUBound(2,localDe), &
2) = 2.5 ! dummy assignment
dodo
deallocate(larrayList)

For some applications the default association rules between DistGrid and Array dimensions may not satisfy the user’s needs. The optional %distgridToArrayMap argument can be used during Array creation to explicitly specify the mapping between DistGrid and Array dimensions. To demonstrate this the following lines of code reproduce the above example but with rearranged dimensions. Here the %distgridToArrayMap argument is a list with two elements corresponding to the DistGrid dimCount of 2. The first element indicates which Array dimension the first DistGrid dimension is mapped against. Here the 1st DistGrid dimension maps against the 3rd Array dimension and the 2nd DistGrid dimension maps against the 1st Array dimension. This leaves the 2nd Array dimension to be the extra and undistributed dimension in the resulting Array object.

call ESMF_ArrayDestroy(array, rc=rc)
array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
%distgridToArrayMap=(/3, 1/), totalLWidth=(/0,1/), totalUWidth=(/0,1/), &
undistLBound=(/1/), undistUBound=(/2/), rc=rc)

Operations on the Array object as a whole are unchanged by the different mapping of dimensions.

When working with Arrays that contain explicitly mapped Array and DistGrid dimensions it is critical to know the order in which the entries of %width and %bound arguments that are associated with distributed Array dimensions are specified. The size of these arguments is equal to the DistGrid dimCount, because the maximum number of distributed Array dimensions is given by the dimensionality of the index space.

The order of dimensions in these arguments, however, is not that of the associated DistGrid. Instead each entry corresponds to the distributed Array dimensions in sequence. In the example above the entries in %totalLWidth and %totalUWidth correspond to Array dimensions 1 and 3 in this sequence.

The %distgridToArrayMap argument optionally provided during Array create indicates how the DistGrid dimensions map to Array dimensions. The inverse mapping, i.e. Array to DistGrid dimensions, is just as important. The ESMF_ArrayGet() call offers both mappings as %distgridToArrayMap and %arrayToDistGridMap, respectively. The number of elements in %arrayToDistGridMap is equal to the rank of the Array. Each element corresponds to an Array dimension and indicates the associated DistGrid dimension by an integer number. An entry of ”0” in %arrayToDistGridMap indicates that the corresponding Array dimension is undistributed.

Correct understanding about the association between Array and DistGrid dimensions becomes critical for correct data access into the Array.

allocate(arrayToDistGridMap(3)) ! arrayRank = 3
call ESMF_ArrayGet(array, arrayToDistGridMap=arrayToDistGridMap, &
exclusiveLBound=exclusiveLBound, exclusiveUBound=exclusiveUBound, &
localDeCount=localDeCount, rc=rc)
if (arrayToDistGridMap(2) /= 0) then ! check if extra dimension at 
! expected index indicate problem and bail out
endif
! obtain larrayList for local DEs
allocate(larrayList(0:localDeCount-1))
call ESMF_ArrayGet(array, localarrayList=larrayList, rc=rc)
do localDe=0, localDeCount-1
call ESMF_LocalArrayGet(larrayList(localDe), myFarray 3D, &
datcopyFlag=ESMF_DATACOPY_REFERENCE, rc=rc)
myFarray3D(exclusiveLBound(1,localDe):exclusiveUBound(1,localDe), &
1, exclusiveLBound(2,localDe):exclusiveUBound(2, &
localDe)) = 10.5 !dummy assignment
myFarray3D(exclusiveLBound(1,localDe):exclusiveUBound(1,localDe), &
2, exclusiveLBound(2,localDe):exclusiveUBound(2, &
localDe)) = 23.3 !dummy assignment
enddo
deallocate(exclusiveLBound, exclusiveUBound)
deallocate(arrayToDistGridMap)
deallocate(larrayList)
call ESMF_ArrayDestroy(array, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

27.2.12 Arrays with replicated dimensions

Thus far most examples demonstrated cases where the DistGrid dimCount was equal to the Array rank. The previous section introduced the concept of Array tensor dimensions when dimCount < rank. In this section dimCount and rank are assumed completely unconstrained and the relationship to distgridToArrayMap and arrayToDistGridMap will be discussed.

The Array class allows completely arbitrary mapping between Array and DistGrid dimensions. Most cases considered in the previous sections used the default mapping which assigns the DistGrid dimensions in sequence to the lower Array dimensions. Extra Array dimensions, if present, are considered non-distributed tensor dimensions for which the optional undistLBound and undistUBound arguments must be specified.

The optional distgridToArrayMap argument provides the option to override the default DistGrid to Array dimension mapping. The entries of the distgridToArrayMap array correspond to the DistGrid dimensions in sequence and assign a unique Array dimension to each DistGrid dimension. DistGrid and Array dimensions are indexed starting at 1 for the lowest dimension. A value of "0" in the distgridToArrayMap array indicates that the respective DistGrid dimension is not mapped against any Array dimension. What this means is that the Array will be replicated along this DistGrid dimension.

As a first example consider the case where a 1D Array

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=1, rc=rc)

is created on the 2D DistGrid used during the previous section.

array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, rc=rc)

Here the default DistGrid to Array dimension mapping is used which assigns the Array dimensions in sequence to the DistGrid dimensions starting with dimension "1". Extra DistGrid dimensions are considered replicator dimensions because the Array will be replicated along those dimensions. In the above example the 2nd DistGrid dimension will cause 1D Array pieces to be replicated along the DEs of the 2nd DistGrid dimension. Replication in the context of ESMF_ArrayCreate() does not mean that data values are communicated and replicated between different DEs, but it means that different DEs provide memory allocations for identical exclusive elements.

Access to the data storage of an Array that has been replicated along DistGrid dimensions is the same as for Arrays without replication.
call ESMF_ArrayGet(array, localDeCount=localDeCount, rc=rc)

allocate(larrayList(0:localDeCount-1))
allocate(localDeToDeMap(0:localDeCount-1))
call ESMF_ArrayGet(array, localarrayList=larrayList, &
localDeToDeMap=localDeToDeMap, rc=rc)

The array object was created without additional padding which means that the bounds of the Fortran array pointer correspond to the bounds of the exclusive region. The following loop will cycle through all local DEs, print the DE number as well as the Fortran array pointer bounds. The bounds should be:

<table>
<thead>
<tr>
<th>lbound</th>
<th>ubound</th>
</tr>
</thead>
<tbody>
<tr>
<td>DE 0:</td>
<td>1</td>
</tr>
<tr>
<td>DE 2:</td>
<td>1</td>
</tr>
<tr>
<td>DE 4:</td>
<td>1</td>
</tr>
<tr>
<td>DE 1:</td>
<td>1</td>
</tr>
<tr>
<td>DE 3:</td>
<td>1</td>
</tr>
<tr>
<td>DE 5:</td>
<td>1</td>
</tr>
</tbody>
</table>

do localDe=0, localDeCount-1
  call ESMF_LocalArrayGet(larrayList(localDe), myFarray1D, &
  datacopyflag=ESMF_DATACOPY_REFERENCE, rc=rc)

  print *, "localPet: ", localPet, "DE ",localDeToDeMap(localDe)," [", &
  lbound(myFarray1D), ubound(myFarray1D),"]"
endo
deallocate(larrayList)
deallocate(localDeToDeMap)
call ESMF_ArrayDestroy(array, rc=rc)

The Fortran array pointer in the above loop was of rank 1 because the Array object was of rank 1. However, the distgrid object associated with array is 2-dimensional! Consequently DistGrid based information queried from array will be 2D. The distgridToArrayMap and arrayToDistGridMap arrays provide the necessary mapping to correctly associate DistGrid based information with Array dimensions.

The next example creates a 2D Array

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)

on the previously used 2D DistGrid. By default, i.e. without the distgridToArrayMap argument, both DistGrid dimensions would be associated with the two Array dimensions. However, the distgridToArrayMap specified in the following call will only associate the second DistGrid dimension with the first Array dimension. This will render the first DistGrid dimension a replicator dimension and the second Array dimension a tensor dimension for which 1D undistLBound and undistUBound arguments must be supplied.
array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
distgridToArrayMap=(/0,1/), undistLBound=(/11/), &
undistUBound=(/14/), rc=rc)

call ESMF_ArrayDestroy(array, rc=rc)

Finally, the same arrayspec and distgrid arguments are used to create a 2D Array that is fully replicated in both dimensions of the DistGrid. Both Array dimensions are now tensor dimensions and both DistGrid dimensions are replicator dimensions.

array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
distgridToArrayMap=(/0,0/), undistLBound=(/11,21/), &
undistUBound=(/14,22/), rc=rc)

The result will be an Array with local lower bound (/11,21/) and upper bound (/14,22/) on all 6 DEs of the DistGrid.

call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

Replicated Arrays can also be created from existing local Fortran arrays. The following Fortran array allocation will provide a 3 x 10 array on each PET.

allocate(myFarray2D(3,10))

Assuming a petCount of 4 the following DistGrid defines a 2D index space that is distributed across the PETs along the first dimension.

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/40,10/), rc=rc)

The following call creates an Array object on the above distgrid using the locally existing myFarray2D Fortran arrays. The difference compared to the case with automatic memory allocation is that instead of arrayspec the Fortran array is provided as argument. Furthermore, the undistLBound and undistUBound arguments can be omitted, defaulting into Array tensor dimension lower bound of 1 and an upper bound equal to the size of the respective Fortran array dimension.

array = ESMF_ArrayCreate(farray=myFarray2D, distgrid=distgrid, &
indexflag=ESMF_INDEX_DELOCAL, distgridToArrayMap=(/0,2/), rc=rc)

The array object associates the 2nd DistGrid dimension with the 2nd Array dimension. The first DistGrid dimension is not associated with any Array dimension and will lead to replication of the Array along the DEs of this direction.
call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

27.2.13 Communication – Scatter and Gather

It is a common situation, particularly in legacy code, that an ESMF Array object must be filled with data originating from a large Fortran array stored on a single PET.

if (localPet == 0) then
allocate(farray(10,20,30))
do j=1, 20
   do i=1, 10
      farray(i, j, k) = k*1000 + j*100 + i
   enddo
endo
dendo
else
allocate(farray(0,0,0))
dendif

distgrid = ESMF_DistGridCreate(minIndex=(/1,1,1/), maxIndex=(/10,20,30/), & rc=rc)

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_I4, rank=3, rc=rc)

call ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, rc=rc)

The ESMF_ArrayScatter() method provides a convenient way of scattering array data from a single root PET across the DEs of an ESMF Array object.

call ESMF_ArrayScatter(array, farray=farray, rootPet=0, rc=rc)

dallocate(farray)

The destination of the ArrayScatter() operation are all the DEs of a single tile. For multi-tile Arrays the destination tile can be specified. The shape of the scattered Fortran array must match the shape of the destination tile in the ESMF Array.

Gathering data decomposed and distributed across the DEs of an ESMF Array object into a single Fortran array on root PET is accomplished by calling ESMF_ArrayGather().
if (localPet == 3) then
    allocate(farray(10,20,30))
else
    allocate(farray(0,0,0))
endif

call ESMF_ArrayGather(array, farray=farray, rootPet=3, rc=rc)

decallocate(farray)

The source of the ArrayGather() operation are all the DEs of a single tile. For multi-tile Arrays the source tile can be specified. The shape of the gathered Fortran array must match the shape of the source tile in the ESMF Array.

The ESMF_ArrayScatter() operation allows to fill entire replicated Array objects with data coming from a single root PET.

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
   regDecomp=(/2,3/), rc=rc)

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)

array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
   distgridToArrayMap=(/0,0/), undistLBound=(/11,21/), &
   undistUBound=(/14,22/), rc=rc)

The shape of the Fortran source array used in the Scatter() call must be that of the contracted Array, i.e. contracted DistGrid dimensions do not count. For the array just created this means that the source array on rootPet must be of shape 4 x 2.

if (localPet == 0) then
    allocate(myFarray2D(4,2))
    do j=1,2
        do i=1,4
            myFarray2D(i,j) = i * 100.d0 + j * 1.2345d0 ! initialize
        enddo
    enddo
else
    allocate(myFarray2D(0,0))
endif

call ESMF_ArrayScatter(array, farray=myFarray2D, rootPet=0, rc=rc)

decallocate(myFarray2D)

This will have filled each local 4 x 2 Array piece with the replicated data of myFarray2D.
call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

As a second example for the use of Scatter() and Gather() consider the following replicated Array created from existing local Fortran arrays.

allocate(myFarray2D(3,10))
distgrid = ESMF_DistGridCreate(minIndex=/(1,1/), maxIndex=/(40,10/), rc=rc)

array = ESMF_ArrayCreate(farray=myFarray2D, distgrid=distgrid, &
indexflag=ESMF_INDEX_DELOCAL, distgridToArrayMap=(/0,2/), rc=rc)

The array object associates the 2nd DistGrid dimension with the 2nd Array dimension. The first DistGrid dimension is not associated with any Array dimension and will lead to replication of the Array along the DEs of this direction. Still, the local arrays that comprise the array object refer to independent pieces of memory and can be initialized independently.

myFarray2D = localPet ! initialize

However, the notion of replication becomes visible when an array of shape 3 x 10 on root PET 0 is scattered across the Array object.

if (localPet == 0) then
allocate(myFarray2D2(5:7,11:20))
    do j=11,20
        do i=5,7
            myFarray2D2(i,j) = i * 100.d0 + j * 1.2345d0 ! initialize
        enddo
    enddo
else
allocate(myFarray2D2(0,0))
endif

call ESMF_ArrayScatter(array, farray=myFarray2D2, rootPet=0, rc=rc)

deallocate(myFarray2D2)

The Array pieces on every DE will receive the same source data, resulting in a replication of data along DistGrid dimension 1.

When the inverse operation, i.e. ESMF_ArrayGather(), is applied to a replicated Array an intrinsic ambiguity needs to be considered. ESMF defines the gathering of data of a replicated Array as the collection of data originating from the numerically higher DEs. This means that data in replicated elements associated with numerically lower DEs will be ignored during ESMF_ArrayGather(). For the current example this means that changing the Array contents on PET 1, which here corresponds to DE 1,
if (localPet == 1) then
    myFarray2D = real(1.2345, ESMF_KIND_R8)
endif

will *not* affect the result of

    allocate(myFarray2D2(3,10))
    myFarray2D2 = 0.d0    ! initialize to a known value
    call ESMF_ArrayGather(array, farray=myFarray2D2, rootPet=0, rc=rc)

The result remains completely defined by the unmodified values of Array in DE 3, the numerically highest DE. However, overriding the DE-local Array piece on DE 3

if (localPet==3) then
    myFarray2D = real(5.4321, ESMF_KIND_R8)
endif

will change the outcome of

    call ESMF_ArrayGather(array, farray=myFarray2D2, rootPet=0, rc=rc)

as expected.

deallocate(myFarray2D2)

call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

27.2.14 Communication – Halo

One of the most fundamental communication pattern in domain decomposition codes is the *halo* operation. The ESMF Array class supports halos by allowing memory for extra elements to be allocated on each DE. See sections 27.2.2 and 27.2.8 for examples and details on how to create an Array with extra DE-local elements.

Here we consider an Array object that is created on a DistGrid that defines a 10 x 20 index space, decomposed into 4 DEs using a regular 2 x 2 decomposition.

distgrid = ESMF_DistGridCreate(minIndex=/(1,1/), maxIndex=/(10,20/), &
    regDecomp=/(2,2/), rc=rc)

The Array holds 2D double precision float data.
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)

The totalLWidth and totalUWidth arguments are used during Array creation to allocate 2 extra elements along every direction outside the exclusive region defined by the DistGrid for every DE. (The indexflag set to ESMF_INDEXGLOBAL in this example does not affect the halo behavior of Array. The setting is simply more convenient for the following code.)

\[
\text{array} = \text{ESMF\_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, } \\
\text{totalLWidth=}(/2,2/), \text{ totalUWidth=}(/2,2/), \text{ indexflag=ESMF\_INDEX\_GLOBAL, } & \\
\text{rc=rc)}
\]

Without the explicit definition of boundary conditions in the DistGrid the following inner connections are defined.

The exclusive region on each DE is of shape 5 x 10, while the total region on each DE is of shape (5+2+2) x (10+2+2) = 9 x 14. In a typical application the elements in the exclusive region are updated exclusively by the PET that owns the DE. In this example the exclusive elements on every DE are initialized to the value \( f(i, j) \) of the geometric function

\[
f(i, j) = \sin(\alpha i) \cos(\beta j),
\]

where

\[
\alpha = 2\pi/N_i, i = 1, \ldots N_i
\]
\[ \beta = 2\pi/N_j, j = 1, \ldots N_j, \]  
(3)

with \( N_i = 10 \) and \( N_j = 20 \).

\[
an = 2. \times 3.14159 / 10. 
\]
\[
b = 2. \times 3.14159 / 20. 
\]

```fortran
    call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc)
    call ESMF_ArrayGet(array, exclusiveLBound=eLB, exclusiveUBound=eUB, rc=rc)

    do j=eLB(2,1), eUB(2,1)
       do i=eLB(1,1), eUB(1,1)
          farrayPtr(i,j) = sin(a*i) * cos(b*j) ! test function
       enddo
    enddo
```

The above loop only initializes the exclusive elements on each DE. The extra elements, outside the exclusive region, are left untouched, holding undefined values. Elements outside the exclusive region that correspond to exclusive elements in neighboring DEs can be filled with the data values in those neighboring elements. This is the definition of the halo operation.

In ESMF the halo communication pattern is first precomputed and stored in a RouteHandle object. This RouteHandle can then be used repeatedly to perform the same halo operation in the most efficient way.

The default halo operation for an Array is precomputed by the following call.

```fortran
    call ESMF_ArrayHaloStore(array=array, routehandle=haloHandle, rc=rc)
```

The `haloHandle` now holds the default halo operation for `array`, which matches as many elements as possible outside the exclusive region to their corresponding halo source elements in neighboring DEs. Elements that could not be matched, e.g. at the edge of the global domain with open boundary conditions, will not be updated by the halo operation.

The `haloHandle` is applied through the `ESMF_ArrayHalo()` method.

```fortran
    call ESMF_ArrayHalo(array=array, routehandle=haloHandle, rc=rc)
```

Finally the resources held by `haloHandle` need to be released.

```fortran
    call ESMF_ArrayHaloRelease(routehandle=haloHandle, rc=rc)
```
The `array` object created above defines a 2 element wide rim around the exclusive region on each DE. Consequently the default halo operation used above will have resulted in updating both elements along the inside edges. For simple numerical kernels often a single halo element is sufficient. One way to achieve this would be to reduce the size of the rim surrounding the exclusive region to 1 element along each direction. However, if the same Array object is also used for higher order kernels during a different phase of the calculation, a larger element rim is required. For this case `ESMF_ArrayHaloStore()` offers two optional arguments `haloLDepth` and `haloUDepth`. Using these arguments a reduced halo depth can be specified.

```fortran
    call ESMF_ArrayHaloStore(array=array, routehandle=haloHandle, &
        haloLDepth=(/1,1/), haloUDepth=(/1,1/), rc=rc)
```

This halo operation with a depth of 1 is sufficient to support a simple quadratic differentiation kernel.

```fortran
allocate(farrayTemp(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)))
d0 step=1, 4
    call ESMF_ArrayHalo(array=array, routehandle=haloHandle, rc=rc)
    do j=eLB(2,1), eUB(2,1)
        do i=eLB(1,1), eUB(1,1)
            if (i==1) then
                ! global edge
                farrayTemp(i,j) = 0.5 * (-farrayPtr(i+2,j) + 4.*farrayPtr(i+1,j) &
                    - 3.*farrayPtr(i,j)) / a
            else if (i==10) then
                ! global edge
                farrayTemp(i,j) = 0.5 * (farrayPtr(i-2,j) - 4.*farrayPtr(i-1,j) &
                    + 3.*farrayPtr(i,j)) / a
            else
                farrayTemp(i,j) = 0.5 * (farrayPtr(i+1,j) - farrayPtr(i-1,j)) / a
            endif
        enddo
    enddo
    farrayPtr(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)) = farrayTemp
deallocate(farrayTemp)
call ESMF_ArrayHaloRelease(routehandle=haloHandle, rc=rc)
```

The special treatment of the global edges in the above kernel is due to the fact that the underlying DistGrid object does not define any special boundary conditions. By default open global boundaries are assumed which means that the rim elements on the global edges are untouched during the halo operation, and cannot be used in the symmetric numerical derivative formula. The kernel can be simplified (and the calculation is more precise) with periodic boundary conditions along the first Array dimension.

First destroy the current Array and DistGrid objects.

```fortran
call ESMF_ArrayDestroy(array, rc=rc)
```
call ESMF_DistGridDestroy(distgrid, rc=rc)

Create a DistGrid with periodic boundary condition along the first dimension.

allocate(connectionList(1)) ! one connection
call ESMF_DistGridConnectionSet(connection=connectionList(1), &
tileIndexA=1, tileIndexB=1, positionVector=(/10, 0/), rc=rc)

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/10,20/), &
regDecomp=(/2,2/), connectionList=connectionList, rc=rc)

dallocate(connectionList)
array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, &
totalLWidth=(/2,2/), totalUWidth=(/2,2/), indexflag=ESMF_INDEX_GLOBAL, &
rc=rc)

Initialize the exclusive elements to the same geometric function as before.

call ESMF_ArrayGet(array, farrayPtr=farrayPtr, rc=rc)

call ESMF_ArrayGet(array, exclusiveLBound=eLB, exclusiveUBound=eUB, rc=rc)

do j=eLB(2,1), eUB(2,1)
do i=eLB(1,1), eUB(1,1)
   farrayPtr(i,j) = sin(a*i) * cos(b*j) ! test function
enddo
enddo

The numerical kernel only operates along the first dimension. An asymmetric halo depth can be used to take this fact into account.

call ESMF_ArrayHaloStore(array=array, routehandle=haloHandle, &
haloLDepth=(/1,0/), haloUDepth=(/1,0/), rc=rc)

Now the same numerical kernel can be used without special treatment of global edge elements. The symmetric derivative formula can be used for all exclusive elements.

allocate(farrayTemp(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)))
do step=1, 4
call ESMF_ArrayHalo(array=array, routehandle=haloHandle, rc=rc)
do j=eLB(2,1), eUB(2,1)
doi=eLB(1,1), eUB(1,1)
farrayTemp(i,j) = 0.5 * (farrayPtr(i+1,j) - farrayPtr(i-1,j)) / a
enddo
dfarrayPtr(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)) = farrayTemp
dendo

do j=eLB(2,1), eUB(2,1)
doi=eLB(1,1), eUB(1,1)
farrayPtr(i,j) = sin(a*i) * cos(b*j) ! test function
enddo
dfarrayPtr(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)) = farrayTemp
dendo

call ESMF_ArrayHaloStore(array=array, routehandle=haloHandle2, &
haloLDepth=(/2,0/), haloUDepth=(/2,0/), rc=rc)

do step=1, 4
call ESMF_ArrayHalo(array=array, routehandle=haloHandle2, rc=rc)
do j=eLB(2,1), eUB(2,1)
doi=eLB(1,1), eUB(1,1)
farrayTemp(i,j) = (-farrayPtr(i+2,j) + 8.*farrayPtr(i+1,j) &
- 8.*farrayPtr(i-1,j) + farrayPtr(i-2,j)) / (12.*a)
enddo
dfarrayPtr(eLB(1,1):eUB(1,1), eLB(2,1):eUB(2,1)) = farrayTemp
dendo
deallocate(farrayTemp)

ESMF supports having multiple halo operations defined on the same Array object at the same time. Each operation can be accessed through its unique RouteHandle. The above kernel could have made ESMF_ArrayHalo() calls with a depth of 1 along the first dimension using the previously precomputed haloHandle if it needed to. Both RouteHandles need to release their resources when no longer used.

call ESMF_ArrayHaloRelease(routehandle=haloHandle, rc=rc)
Finally the Array and DistGrid objects can be destroyed.

call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

### 27.2.15 Communication – Halo for arbitrary distribution

In the previous section the Array halo operation was demonstrated for regularly decomposed ESMF Arrays. However, the ESMF halo operation is not restricted to regular decompositions. The same Array halo methods apply unchanged to Arrays that are created on arbitrarily distributed DistGrids. This includes the non-blocking features discussed in section 27.2.19.

All of the examples in this section are based on the same arbitrarily distributed DistGrid. Section 34.3.6 discusses DistGrids with user-supplied, arbitrary sequence indices in detail. Here a global index space range from 1 through 20 is decomposed across 4 DEs. There are 4 PETs in this example with 1 DE per PET. Each PET constructs its local seqIndexList variable.

```fortran
    do i=1, 5
        seqIndexList(i) = localPet + (i - 1) * petCount + 1
    enddo
```

This results in the following cyclic distribution scheme:

- **DE 0 on PET 0:** seqIndexList = (/1, 5, 9, 13, 17/)
- **DE 1 on PET 1:** seqIndexList = (/2, 6, 10, 14, 18/)
- **DE 2 on PET 2:** seqIndexList = (/3, 7, 11, 15, 19/)
- **DE 3 on PET 3:** seqIndexList = (/4, 8, 12, 16, 20/)

The local seqIndexList variables are then used to create a DistGrid with the indicated arbitrary distribution pattern.

```fortran
    distgrid = ESMF_DistGridCreate(arbSeqIndexList=seqIndexList, rc=rc)
```

The resulting DistGrid is one-dimensional, although the user code may interpret the sequence indices as a 1D map into a problem of higher dimensionality.

In this example the local DE on each PET is associated with a 5 element exclusive region. Providing seqIndexList of different size on the different PETs is supported and would result in different number of exclusive elements on each PET.

Creating an ESMF Array on top of a DistGrid with arbitrary sequence indices is in principle no different from creating an Array on a regular DistGrid. However, while an Array that was created on a regular DistGrid automatically inherits the index space topology information that is contained within the DistGrid object, there is no such topology information...
available for DistGrid objects with arbitrary sequence indices. As a consequence of this, Arrays created on arbitrary DistGrids do not automatically have the information that is required to associated halo elements with the exclusive elements across DEs. Instead the user must supply this information explicitly during Array creation.

Multiple ArrayCreate() interfaces exist that allow the creation of an Array on a DistGrid with arbitrary sequence indices. The sequence indices for the halo region of the local DE are supplied through an additional argument with dummy name haloSeqIndexList. As in the regular case, the ArrayCreate() interfaces differ in the way that the memory allocations for the Array elements are passed into the call. The following code shows how an ESMF Array can be wrapped around existing PET-local memory allocations. The allocations are of different size on each PET as to accommodate the correct number of local Array elements (exclusive region + halo region).

```fortran
allocate(farrayPtr1d(5+localPet+1)) !use explicit Fortran allocate statement
if (localPet==0) then
array = ESMF_ArrayCreate(distgrid, farrayPtr1d, 
haloSeqIndexList=(/6/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==1) then
array = ESMF_ArrayCreate(distgrid, farrayPtr1d, 
haloSeqIndexList=(/1,19/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==2) then
array = ESMF_ArrayCreate(distgrid, farrayPtr1d, 
haloSeqIndexList=(/16,6,9/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==3) then
array = ESMF_ArrayCreate(distgrid, farrayPtr1d, 
haloSeqIndexList=(/1,3,1,4/), rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
```

The `haloSeqIndexList` arguments are 1D arrays of sequence indices. It is through this argument that the user associates the halo elements with exclusive Array elements covered by the DistGrid. In this example there are different number of halo elements on each DE. They are associated with exclusive elements as follows:

- halo on DE 0 on PET 0: `<seqIndex=6>` 2nd exclusive element on DE 1
- halo on DE 1 on PET 1: `<seqIndex=1>` 1st exclusive element on DE 0
- `<seqIndex=19>` 5th exclusive element on DE 2
- halo on DE 2 on PET 2: `<seqIndex=16>` 4th exclusive element on DE 3
- `<seqIndex=6>` 2nd exclusive element on DE 1
- `<seqIndex=9>` 3rd exclusive element on DE 0
- halo on DE 3 on PET 3: `<seqIndex=1>` 1st exclusive element on DE 0
- `<seqIndex=3>` 1st exclusive element on DE 2
- `<seqIndex=1>` 1st exclusive element on DE 0
- `<seqIndex=4>` 1st exclusive element on DE 3

The above `haloSeqIndexList` arguments were constructed very artificially in order to show the following general features:

- There is no restriction on the order in which the indices in a `haloSeqIndexList` can appear.
The same sequence index may appear in multiple `haloSeqIndexList` arguments.

The same sequence index may appear multiple times in the same `haloSeqIndexList` argument.

A local sequence index may appear in a `haloSeqIndexList` argument.

The `ArrayCreate()` call checks that the provided Fortran memory allocation is correctly sized to hold the exclusive elements, as indicated by the DistGrid object, plus the halo elements as indicated by the local `haloSeqIndexList` argument. The size of the Fortran allocation must match exactly or a runtime error will be returned.

Analogous to the case of Arrays on regular DistGrids, it is the exclusive region of the local DE that is typically modified by the code running on each PET. All of the `ArrayCreate()` calls that accept the `haloSeqIndexList` argument place the exclusive region at the beginning of the memory allocation on each DE and use the remaining space for the halo elements. The following loop demonstrates this by filling the exclusive elements on each DE with initial values. Remember that in this example each DE holds 5 exclusive elements associated with different arbitrary sequence indices.

```fortran
do i=1, 5
    farrayPtr1d(i) = seqIndexList(i) / 10.
enddo
```

Now the exclusive elements of `array` are initialized on each DE, however, the halo elements remain unchanged. A `RouteHandle` can be set up that encodes the required communication pattern for a halo exchange. The halo exchange is precomputed according to the arbitrary sequence indices specified for the exclusive elements by the DistGrid and the sequence indices provided by the user for each halo element on the local DE in form of the `haloSeqIndexList` argument during `ArrayCreate()`.

```fortran
call ESMF_ArrayHaloStore(array, routehandle=haloHandle, rc=rc)
```

Executing this halo operation will update the local halo elements according to the associated sequence indices.

```fortran
call ESMF_ArrayHalo(array, routehandle=haloHandle, rc=rc)
```

As always it is good practice to release the `RouteHandle` when done with it.

```fortran
call ESMF_ArrayHaloRelease(haloHandle, rc=rc)
```

Also the `Array` object should be destroyed when no longer needed.

```fortran
call ESMF_ArrayDestroy(array, rc=rc)
```

Further, since the memory allocation was done explicitly using the Fortran `allocate()` statement, it is necessary to explicitly deallocate in order to prevent memory leaks in the user application.

```fortran
deallocate(farrayPtr1d)
```
Alternatively the exact same Array can be created where ESMF does the memory allocation and deallocation. In this case the typekind of the Array must be specified explicitly.

```fortran
if (localPet==0) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
        haloSeqIndexList=(/6/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==1) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
        haloSeqIndexList=(/1,19/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==2) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
        haloSeqIndexList=(/16,6,9/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==3) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
        haloSeqIndexList=(/1,3,1,4/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
```

Use ArrayGet() to gain access to the local memory allocation.

```fortran
call ESMF_ArrayGet(array, farrayPtr=farrayPtr1d, rc=rc)
```

The returned Fortran pointer can now be used to initialize the exclusive elements on each DE as in the previous case.

```fortran
do i=1, 5
    farrayPtr1d(i) = seqIndexList(i) / 10.
enddo
```

Identical halo operations are constructed and used.

```fortran
call ESMF_ArrayHaloStore(array, routehandle=haloHandle, rc=rc)
call ESMF_ArrayHalo(array, routehandle=haloHandle, rc=rc)
call ESMF_ArrayHaloRelease(haloHandle, rc=rc)
call ESMF_ArrayDestroy(array, rc=rc)
```
A current limitation of the Array implementation restricts DistGrids that contain user-specified, arbitrary sequence indices to be exactly 1D when used to create Arrays. See section 27.3 for a list of current implementation restrictions. However, an Array created on such a 1D arbitrary DistGrid is allowed to have undistributed dimensions. The following example creates an Array on the same arbitrary DistGrid, with the same arbitrary sequence indices for the halo elements as before, but with one undistributed dimension with a size of 3.

```fortran
if (localPet==0) then
   array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, 
   haloSeqIndexList=(/6/), undistLBound=(/1/), undistUBound=(/3/), rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==1) then
   array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, 
   haloSeqIndexList=(/1,19/), undistLBound=(/1/), undistUBound=(/3/), 
   rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==2) then
   array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, 
   haloSeqIndexList=(/16,6,9/), undistLBound=(/1/), undistUBound=(/3/), 
   rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==3) then
   array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, 
   haloSeqIndexList=(/1,3,1,4/), undistLBound=(/1/), undistUBound=(/3/), 
   rc=rc)
   if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
```

By default the DistGrid dimension is mapped to the first Array dimension, associating the remaining Array dimensions with the undistributed dimensions in sequence. The dimension order is important when accessing the individual Array elements. Here the same initialization as before is extended to cover the undistributed dimension.

```fortran
call ESMF_ArrayGet(array, farrayPtr=farrayPtr2d, rc=rc)
```

```fortran
do j=1, 3
   do i=1, 5
      farrayPtr2d(i,j) = seqIndexList(i) / 10. + 100.*j
   enddo
endo
dodo
```

In the context of the Array halo operation additional undistributed dimensions are treated in a simple factorized manner. The same halo association between elements that is encoded in the 1D arbitrary sequence index scheme is applied to each undistributed element separately. This is completely transparent on the user level and the same halo methods are used as before.

```fortran
call ESMF_ArrayHaloStore(array, routehandle=haloHandle, rc=rc)
```
call ESMF_ArrayHalo(array, routehandle=haloHandle, rc=rc)

call ESMF_ArrayHaloRelease(haloHandle, rc=rc)

call ESMF_ArrayDestroy(array, rc=rc)

In some situations it is more convenient to associate some or all of the undistributed dimensions with the first Array dimensions. This can be done easily by explicitly mapping the DistGrid dimension to an Array dimension other than the first one. The following code creates essentially the same Array as before, but with swapped dimension order.

```fortran
if (localPet==0) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                               distgridToArrayMap=(/2/), haloSeqIndexList=(/1/), &
                               undistLBound=(/1/), undistUBound=(/3/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==1) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                               distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2/), &
                               undistLBound=(/1/), undistUBound=(/3/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==2) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                               distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2,3/), &
                               undistLBound=(/1/), undistUBound=(/3/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==3) then
    array = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                               distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2,3,4/), &
                               undistLBound=(/1/), undistUBound=(/3/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

The swapped dimension order results in a swapping of $i$ and $j$ when accessing Array elements in the loop.

call ESMF_ArrayGet(array, farrayPtr=farrayPtr2d, rc=rc)

do j=1, 3
    do i=1, 5
        farrayPtr2d(j,i) = seqIndexList(i) / 10. + 100.*j
    enddo
enddo
```

Again there is no difference in how the the halo operations are applied.
call ESMF_ArrayHaloStore(array, routehandle=haloHandle, rc=rc)

call ESMF_ArrayHalo(array, routehandle=haloHandle, rc=rc)

call ESMF_ArrayDestroy(array, rc=rc)

One of the benefits of mapping the undistributed dimension(s) to the "left side" of the Array dimensions is that Arrays that only differ in the size of the undistributed dimension(s) are weakly congruent in this arrangement. Weakly congruent Arrays can reuse the same RouteHandle, saving the overhead that is caused by the precompute step. In order to demonstrate this the RouteHandle of the previous halo call was not yet released and will be applied to a weakly congruent Array.

The following code creates an Array that is weakly congruent to the the previous Array by using the same input information as before, only that the size of the undistributed dimension is now 6 instead of 3.

```fortran
if (localPet==0) then
    array2 = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                           distgridToArrayMap=(/2/), haloSeqIndexList=(/1/), &
                           undistLBound=(/1/), undistUBound=(/6/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==1) then
    array2 = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                           distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2/), &
                           undistLBound=(/1/), undistUBound=(/6/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==2) then
    array2 = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                           distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2,3/), &
                           undistLBound=(/1/), undistUBound=(/6/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif
if (localPet==3) then
    array2 = ESMF_ArrayCreate(distgrid=distgrid, typekind=ESMF_TYPEKIND_R8, &
                           distgridToArrayMap=(/2/), haloSeqIndexList=(/1,2,3,4/), &
                           undistLBound=(/1/), undistUBound=(/6/), rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

Again the exclusive Array elements must be initialized.

call ESMF_ArrayGet(array2, farrayPtr=farrayPtr2d, rc=rc)

    do j=1, 6
        do i=1, 5
            farrayPtr2d(j,i) = seqIndexList(i) / 10. + 100.*j
        enddo
    enddo
```
Now the `haloHandle` that was previously pre-computed for `array` can be used directly for the weakly congruent `array2`.

```fortran
    call ESMF_ArrayHalo(array2, routehandle=haloHandle, rc=rc)
```

Release the `RouteHandle` after its last use and clean up the remaining `Array` and `DistGrid` objects.

```fortran
    call ESMF_ArrayHaloRelease(haloHandle, rc=rc)
    call ESMF_ArrayDestroy(array2, rc=rc)
    call ESMF_DistGridDestroy(distgrid, rc=rc)
```

### 27.2.16 Communication – Redist

Arrays used in different models often cover the same index space region, however, the distribution of the Arrays may be different, e.g. the models run on exclusive sets of PETs. Even if the Arrays are defined on the same list of PETs the decomposition may be different.

```fortran
    srcDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/10,20/), &
                                        regDecomp=(/4,1/), rc=rc)
    dstDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/10,20/), &
                                        regDecomp=(/1,4/), rc=rc)
```

The number of elements covered by `srcDistgrid` is identical to the number of elements covered by `dstDistgrid` – in fact the index space regions covered by both `DistGrid` objects are congruent.

```fortran
    call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)
    srcArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=srcDistgrid, rc=rc)
    dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, rc=rc)
```

By construction `srcArray` and `dstArray` are of identical type and kind. Further the number of exclusive elements matches between both Arrays. These are the prerequisites for the application of an Array redistribution in default mode. In order to increase performance of the actual redistribution the communication pattern is precomputed and stored in an `ESMF_RouteHandle` object.
The `redistHandle` can now be used repeatedly on the `srcArray, dstArray` pair to redistributed data from source to destination Array.

```
call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)
```

The use of the precomputed `redistHandle` is not restricted to the `(srcArray, dstArray)` pair. Instead the `redistHandle` can be used to redistribute data between any two Arrays that are weakly congruent to the Array pair used during precomputation. Arrays are congruent if they are defined on DistGrids that match with `ESMF_DISTGRIDMATCH_EXACT` or higher, and have matching DE-local array allocations (i.e. the same amount of padding around the exclusive region as well as the same shape in the undistributed dimensions). For Arrays to be weakly congruent the shape and size of the undistributed dimensions that have a smaller stride than the first distributed dimension need not be the same. This definition covers even the case where an Array does not have any undistributed dimensions.

For instance, an Array where the first two dimensions are undistributed, and are of size 5 and 6 (i.e. undistributed shape `(5,6)`), is weakly congruent to an Array that only has a single undistributed first dimension. Furthermore, the size of this single undist hybrid dimension is not restricted by the number of undistributed elements in the first Array (i.e. here it does not have to be `5x6=30`). The Array is also weakly congruent to an Array that does not have a first undistributed dimension at all. In either case the only restriction is that the distributed dimensions must be congruent.

The transferability of RouteHandles between Array pairs that are weakly congruent can greatly reduce the number of communication store calls needed. In a typical application Arrays are often defined on the same decomposition, typically leading to congruent distributed dimensions. However, these Arrays do not always have the same shape or size in the undistributed dimensions.

For the current case, the `redistHandle` was precomputed for simple 2D Arrays without undistributed dimensions. The RouteHandle transferability rule allows us to use this same RouteHandle to redistribute between two 3D Array that are built on the same 2D DistGrid, but have an undistributed dimension that has a smaller stride than the distributed dimensions.

```
call ESMF_ArraySpecSet(arrayspec3d, typekind=ESMF_TYPEKIND_R8, rank=3, rc=rc)

call ESMF_ArrayCreate(arrayspec=arrayspec3d, distgrid=srcDistgrid, &
distgridToArrayMap=(/2,3/), undistLBound=(/1/), undistUBound=(/10/), rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray1, dstArray=dstArray1, &
routehandle=redistHandle, rc=rc)
```

The following variation of the code shows that the same RouteHandle can be applied to an Array pair where the number of undistributed dimensions does not match between source and destination Array. The two requirements are
simply that each side is weakly congruent to the Array used during store, and that the total number of undistributed elements on source and destination side is the same. Here we prepare a source Array with two leading undistributed dimensions that multiply out to $2 \times 5 = 10$ undistributed elements. The destination array is the same as before with only a single leading undistributed dimension of size 10.

call ESMF_ArraySpecSet(arrayspec4d, typekind=ESMF_TYPEKIND_R8, rank=4, rc=rc)

gsrcArray2 = ESMF_ArrayCreate(arrayspec=arrayspec4d, distgrid=srcDistgrid, &
distgridToArrayMap=(/3,4/), undistLBound=(/1,1/), undistUBound=(/2,5/), &
rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray2, dstArray=dstArray1, &
routehandle=redistHandle, rc=rc)

When done, the resources held by redistHandle need to be deallocated by the user code before the RouteHandle becomes inaccessible.

call ESMF_ArrayRedistRelease(routehandle=redistHandle, rc=rc)

In default mode, i.e. without providing the optional srcToDstTransposeMap argument, ESMF_ArrayRedistStore() does not require equal number of dimensions in source and destination Array. Only the total number of elements must match. Specifying srcToDstTransposeMap switches ESMF_ArrayRedistStore() into transpose mode. In this mode each dimension of srcArray is uniquely associated with a dimension in dstArray, and the sizes of associated dimensions must match for each pair.

dstDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/20,10/), &
rc=rc)

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, rc=rc)

This dstArray object covers a 20 x 10 index space while the srcArray, defined further up, covers a 10 x 20 index space. Setting srcToDstTransposeMap = (/2,1/) will associate the first and second dimension of srcArray with the second and first dimension of dstArray, respectively. This corresponds to a transpose of dimensions. Since the decomposition and distribution of dimensions may be different for source and destination redistribution may occur at the same time.

call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, srcToDstTransposeMap=(/2,1/), rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)
The transpose mode of ESMF_ArrayRedist() is not limited to distributed dimensions of Arrays. The srcToDstTransposeMap argument can be used to transpose undistributed dimensions in the same manner. Furthermore transposing distributed and undistributed dimensions between Arrays is also supported.

The srcArray used in the following examples is of rank 4 with 2 distributed and 2 undistributed dimensions. The distributed dimensions are the two first dimensions of the Array and are distributed according to the srcDistgrid which describes a total index space region of 100 x 200 elements. The last two Array dimensions are undistributed dimensions of size 2 and 3, respectively.

```fortran
! Example 1: Transpose undistributed dimensions
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=4, rc=rc)

srcDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/100,200/), &
                                   rc=rc)

srcArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=srcDistgrid, &
                            undistLBound=(/1,1/), undistUBound=(/2,3/), rc=rc)
```

The first dstArray to consider is defined on a DistGrid that also describes a 100 x 200 index space region. The distribution indicated by dstDistgrid may be different from the source distribution. Again the first two Array dimensions are associated with the DistGrid dimensions in sequence. Furthermore, the last two Array dimensions are undistributed dimensions, however, the sizes are 3 and 2, respectively.

```fortran
! Example 2: Transpose undistributed dimensions
dstDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/100,200/), &
                                   rc=rc)

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
                            undistLBound=(/1,1/), undistUBound=(/3,2/), rc=rc)
```

The desired mapping between srcArray and dstArray dimensions is expressed by srcToDstTransposeMap = (/1,2,4,3/). transposing only the two undistributed dimensions.

```fortran
! Example 3: Transpose undistributed dimensions
call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
                           routehandle=redistHandle, srcToDstTransposeMap=(/1,2,4,3/), rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
                      routehandle=redistHandle, rc=rc)
```

Next consider a dstArray that is defined on the same dstDistgrid, but with a different order of Array dimensions. The desired order is specified during Array creation using the argument distgridToArrayMap = (/2,3/). This map associates the first and second DistGrid dimensions with the second and third Array dimensions, respectively, leaving Array dimensions one and four undistributed.

```fortran
! Example 4: Transpose undistributed dimensions
dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
                             distgridToArrayMap=(/2,3/), undistLBound=(/1,1/), undistUBound=(/3,2/), &
                             rc=rc)
```
Again the sizes of the undistributed dimensions are chosen in reverse order compared to `srcArray`. The desired transpose mapping in this case will be `srcToDstTransposeMap = (/2,3,4,1/)`.

```fortran
call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
  routehandle=redistHandle, srcToDstTransposeMap=(/2,3,4,1/), rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
  routehandle=redistHandle, rc=rc)
```

Finally consider the case where `dstArray` is constructed on a 200 x 3 index space and where the undistributed dimensions are of size 100 and 2.

```fortran
dstDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/200,3/), &
  rc=rc)

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
  undistLBound=(/1,1/), undistUBound=(/100,2/), rc=rc)
```

By construction `srcArray` and `dstArray` hold the same number of elements, albeit in a very different layout. Nevertheless, with a `srcToDstTransposeMap` that maps matching dimensions from source to destination an Array redistribution becomes a well defined operation between `srcArray` and `dstArray`.

```fortran
call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
  routehandle=redistHandle, srcToDstTransposeMap=(/3,1,4,2/), rc=rc)

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
  routehandle=redistHandle, rc=rc)
```

The default mode of Array redistribution, i.e. without providing a `srcToDstTransposeMap` to `ESMF_ArrayRedistStore()`, also supports undistributed Array dimensions. The requirement in this case is that the total undistributed element count, i.e. the product of the sizes of all undistributed dimensions, be the same for source and destination Array. In this mode the number of undistributed dimensions need not match between source and destination.

```fortran
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=4, rc=rc)

call ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/10,20/), &
  regDecomp=(/4,1/), rc=rc)

call ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=srcDistgrid, &
  undistLBound=(/1,1/), undistUBound=(/2,4/), rc=rc)
```
dstDistgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/10,20/), &
regDecomp=(/1,4/), rc=rc)

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
distgridToArrayMap=(/2,3/), undistLBound=(/1,1/), undistUBound=(/2,4/), &
crc=rc)

Both srcArray and dstArray have two undistributed dimensions and a total count of undistributed elements of
$2 \times 4 = 8$.

The Array redistribution operation is defined in terms of sequentialized undistributed dimensions. In the above case
this means that a unique sequence index will be assigned to each of the 8 undistributed elements. The sequence indices
will be 1, 2, ..., 8, where sequence index 1 is assigned to the first element in the first (i.e. fastest varying in memory)
undistributed dimension. The following undistributed elements are labeled in consecutive order as they are stored in
memory.

call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)

The redistribution operation by default applies the identity operation between the elements of undistributed dimen-
sions. This means that source element with sequence index 1 will be mapped against destination element with sequence
index 1 and so forth. Because of the way source and destination Arrays in the current example were constructed this
corresponds to a mapping of dimensions 3 and 4 on srcArray to dimensions 1 and 4 on dstArray, respectively.

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)

Array redistribution does not require the same number of undistributed dimensions in source and destination Array,
merely the total number of undistributed elements must match.

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=3, rc=rc)

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
distgridToArrayMap=(/1,3/), undistLBound=(/11/), undistUBound=(/18/), &
crc=rc)

This dstArray object only has a single undistributed dimension, while the srcArray, defined further back, has
two undistributed dimensions. However, the total undistributed element count for both Arrays is 8.

call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)

In this case the default identity operation between the elements of undistributed dimensions corresponds to a merging
of dimensions 3 and 4 on srcArray into dimension 2 on dstArray.

call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
routehandle=redistHandle, rc=rc)
27.2.17 Communication – SparseMatMul

Sparse matrix multiplication is a fundamental Array communication method. One frequently used application of this method is the interpolation between pairs of Arrays. The principle is this: the value of each element in the exclusive region of the destination Array is expressed as a linear combination of potentially all the exclusive elements of the source Array. Naturally most of the coefficients of these linear combinations will be zero and it is more efficient to store explicit information about the non-zero elements than to keep track of all the coefficients.

There is a choice to be made with respect to the format in which to store the information about the non-zero elements. One option is to store the value of each coefficient together with the corresponding destination element index and source element index. Destination and source indices could be expressed in terms of the corresponding DistGrid tile index together with the coordinate tuple within the tile. While this format may be the most natural way to express elements in the source and destination Array, it has two major drawbacks. First the coordinate tuple is dimCount specific and second the format is extremely bulky. For 2D source and destination Arrays it would require 6 integers to store the source and destination element information for each non-zero coefficient and matters get worse for higher dimensions.

Both problems can be circumvented by interpreting source and destination Arrays as sequentialized strings or vectors of elements. This is done by assigning a unique sequence index to each exclusive element in both Arrays. With that the operation of updating the elements in the destination Array as linear combinations of source Array elements takes the form of a sparse matrix multiplication.

The default sequence index rule assigns index 1 to the minIndex corner element of the first tile of the DistGrid on which the Array is defined. It then increments the sequence index by 1 for each element running through the DistGrid dimensions by order. The index space position of the DistGrid tiles does not affect the sequence labeling of elements. The default sequence indices for

\[
\text{srcDistgrid} = \text{ESMF\_DistGridCreate}(\text{minIndex}=(-1,0), \text{maxIndex}=(/1,3/), \text{rc}=\text{rc})
\]

for each element are:

```
-------------------------------------> 2nd dim
| +------+------+------+------|
| |(-1,0)| | |(-1,3) |
| | 1 | 4 | 7 | 10 |
|+------+------+------+------|
| | 2 | 5 | 8 | 11 |
|+------+------+------+------|
| | (1,0)| | | (1,3) |
| | 3 | 6 | 9 | 12 |
+------+------+------+------+
```

1st dim

The assigned sequence indices are decomposition and distribution invariant by construction. Furthermore, when an Array is created with extra elements per DE on a DistGrid the sequence indices (which only cover the exclusive elements) remain unchanged.
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)

srcArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=srcDistgrid, &
totalLWidth=(/1,1/), totalUWidth=(/1,1/), indexflag=ESMF_INDEX_GLOBAL, &
rc=rc)

The extra padding of 1 element in each direction around the exclusive elements on each DE are “invisible” to the Array
spare matrix multiplication method. These extra elements are either updated by the computational kernel or by Array
halo operations.

An alternative way to assign sequence indices to all the elements in the tiles covered by a DistGrid object is to use
a special ESMF_DistGridCreate() call. This call has been specifically designed for 1D cases with arbitrary,
user-supplied sequence indices.

seqIndexList(1) = localPet*10
seqIndexList(2) = localPet*10 + 1
dstDistgrid = ESMF_DistGridCreate(arbSeqIndexList=seqIndexList, rc=rc)

This call to ESMF_DistGridCreate() is collective across the current VM. The arbSeqIndexList argument
specifies the PET-local arbitrary sequence indices that need to be covered by the local DE. The resulting DistGrid has
one local DE per PET which covers the entire PET-local index range. The user supplied sequence indices must be
unique, but the sequence may be interrupted. The four DEs of dstDistgrid have the following local 1D index
space coordinates (given between “()”) and sequence indices:

<table>
<thead>
<tr>
<th>covered by DE 0</th>
<th>covered by DE 1</th>
<th>covered by DE 2</th>
<th>covered by DE 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>on PET 0</td>
<td>on PET 1</td>
<td>on PET 2</td>
<td>on PET 3</td>
</tr>
<tr>
<td>(1) : 0</td>
<td>(1) : 10</td>
<td>(1) : 20</td>
<td>(1) : 30</td>
</tr>
<tr>
<td>(2) : 1</td>
<td>(2) : 11</td>
<td>(2) : 21</td>
<td>(2) : 31</td>
</tr>
</tbody>
</table>

Again the DistGrid object provides the sequence index labeling for the exclusive elements of an Array created on the
DistGrid regardless of extra, non-exclusive elements.

dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, rc=rc)

With the definition of sequence indices, either by the default rule or as user provided arbitrary sequence indices, it
is now possible to uniquely identify each exclusive element in the source and destination Array by a single integer
number. Specifying a pair of source and destination elements takes two integer number regardless of the number of
dimensions.

The information required to carry out a sparse matrix multiplication are the pair of source and destination
sequence indices and the associated multiplication factor for each pair. ESMF requires this information in
form of two Fortran arrays. The factors are stored in a 1D array of the appropriate type and kind, e.g.
real(ESMF_KIND_R8)::factorList(:). Array sparse matrix multiplications are supported between Arrays
of different type and kind. The type and kind of the factors can also be chosen freely. The sequence index pairs
associated with the factors provided by factorList are stored in a 2D Fortran array of default integer kind of the
shape integer::factorIndexList(2,:). The sequence indices of the source Array elements are stored in the
first row of factorIndexList while the sequence indices of the destination Array elements are stored in the
second row.
Each PET in the current VM must call into `ESMF_ArraySMMStore()` to precompute and store the communication pattern for the sparse matrix multiplication. The multiplication factors may be provided in parallel, i.e. multiple PETs may specify `factorList` and `factorIndexList` arguments when calling into `ESMF_ArraySMMStore()`. PETs that do not provide factors either call with `factorList` and `factorIndexList` arguments containing zero elements or issue the call omitting both arguments.

```fortran
if (localPet == 0) then
allocate(factorList(1)) ! PET 0 specifies 1 factor
allocate(factorIndexList(2,1))
factorList = (/0.2/) ! factors
factorIndexList(1,:) = (/5/) ! seq indices into srcArray
factorIndexList(2,:) = (/30/) ! seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
deallocate(factorList)
deallocate(factorIndexList)
else if (localPet == 1) then
allocate(factorList(3)) ! PET 1 specifies 3 factor
allocate(factorIndexList(2,3))
factorList = (/0.5, 0.5, 0.8/) ! factors
factorIndexList(1,:) = (/8, 2, 12/) ! seq indices into srcArray
factorIndexList(2,:) = (/11, 11, 30/) ! seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
deallocate(factorList)
deallocate(factorIndexList)
else
! PETs 2 and 3 do not provide factors
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, rc=rc)
endif
```

The RouteHandle object `sparseMatMulHandle` produced by `ESMF_ArraySMMStore()` can now be used to call `ESMF_ArraySMM()` collectively across all PETs of the current VM to perform

```fortran
dstArray = 0.0
do n=1, size(combinedFactorList)
dstArray(combinedFactorIndexList(2, n)) +=
```

480
combinedFactorList(n) * srcArray(combinedFactorIndexList(1, n))
enddo

in parallel. Here combinedFactorList and combinedFactorIndexList are the combined lists defined by the respective local lists provided by PETs 0 and 1 in parallel. For this example

call ESMF_ArraySMM(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, rc=rc)

will initialize the entire dstArray to 0.0 and then update two elements:

on DE 1:
dstArray(2) = 0.5 * srcArray(0,0) + 0.5 * srcArray(0,2)

and

on DE 3:
dstArray(1) = 0.2 * srcArray(0,1) + 0.8 * srcArray(1,3).

The call to ESMF_ArraySMM() does provide the option to turn the default dstArray initialization off. If argument zeroregion is set to ESMF_REGION_EMPTY

call ESMF_ArraySMM(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, zeroregion=ESMF_REGION_EMPTY, rc=rc)

skips the initialization and elements in dstArray are updated according to:

do n=1, size(combinedFactorList)
    dstArray(combinedFactorIndexList(2, n)) +=
        combinedFactorList(n) * srcArray(combinedFactorIndexList(1, n)).
enddo

The ESMF_RouteHandle object returned by ESMF_ArraySMMStore() can be applied to any src/dst Array pairs that are weakly congruent to the Array pair used during precomputation. Arrays are congruent if they are defined on matching DistGrids and the shape of local array allocations match for all DEs. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. See section 27.2.16 for an example of this feature demonstrated for the Redist case. The exact same principle applies to the SMM case.

The resources held by sparseMatMulHandle need to be deallocated by the user code before the handle becomes inaccessible.

call ESMF_ArraySMMRelease(routehandle=sparseMatMulHandle, rc=rc)
The Array sparse matrix multiplication also applies to Arrays with undistributed dimensions. The undistributed dimensions are interpreted in a sequentialized manner, much like the distributed dimensions, introducing a second sequence index for source and destination elements. Sequence index 1 is assigned to the first element in the first (i.e. fastest varying in memory) undistributed dimension. The following undistributed elements are labeled in consecutive order as they are stored in memory.

In the simplest case the Array sparse matrix multiplication will apply an identity matrix to the vector of sequentialized undistributed Array elements for every non-zero element in the sparse matrix. The requirement in this case is that the total undistributed element count, i.e. the product of the sizes of all undistributed dimensions, be the same for source and destination Array.

```fortran
if (localPet == 0) then
allocate(factorList(1)) ! PET 0 specifies 1 factor
allocate(factorIndexList(2,1))
factorList = (/0.2/) ! factors
factorIndexList(1,:) = (/5/) ! seq indices into srcArray
factorIndexList(2,:) = (/30/) ! seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
deallocate(factorList)
deallocate(factorIndexList)
else if (localPet == 1) then
allocate(factorList(3)) ! PET 1 specifies 3 factor
allocate(factorIndexList(2,3))
factorList = (/0.5, 0.5, 0.8/) ! factors
factorIndexList(1,:) = (/8, 2, 12/) ! seq indices into srcArray
factorIndexList(2,:) = (/11, 11, 30/) ! seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
```

Setting up `factorList` and `factorIndexList` is identical to the case for Arrays without undistributed dimensions. Also the call to `ESMF_ArraySMMStore()` remains unchanged. Internally, however, the source and destination Arrays are checked to make sure the total undistributed element count matches.
deallocate(factorList)
deallocate(factorIndexList)
else
! PETs 2 and 3 do not provide factors

call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routinehandle=sparseMatMulHandle, rc=rc)

endif

The call into the ESMF_ArraySMM() operation is completely transparent with respect to whether source and/or
destination Arrays contain undistributed dimensions.

call ESMF_ArraySMM(srcArray=srcArray, dstArray=dstArray, &
routinehandle=sparseMatMulHandle, rc=rc)

This operation will initialize the entire dstArray to 0.0 and then update four elements:

on DE 1:
dstArray[1](2) = 0.5 * srcArray(0,0)[1] + 0.5 * srcArray(0,2)[1],
dstArray[2](2) = 0.5 * srcArray(0,0)[2] + 0.5 * srcArray(0,2)[2]

and

on DE 3:
dstArray[1](1) = 0.2 * srcArray(0,1)[1] + 0.8 * srcArray(1,3)[1],
dstArray[2](1) = 0.2 * srcArray(0,1)[2] + 0.8 * srcArray(1,3)[2].

Here indices between "()" refer to distributed dimensions while indices between "[]" correspond to undistributed
dimensions.

In a more general version of the Array sparse matrix multiplication the total undistributed element count, i.e. the
product of the sizes of all undistributed dimensions, need not be the same for source and destination Array. In this
formulation each non-zero element of the sparse matrix is identified with a unique element in the source and destination
Array. This requires a generalization of the factorIndexList argument which now must contain four integer
numbers for each element. These numbers in sequence are the sequence index of the distributed dimensions and the
sequence index of the undistributed dimensions of the element in the source Array, followed by the sequence index of
the distributed dimensions and the sequence index of the undistributed dimensions of the element in the destination
Array.

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPE_KIND_R8, rank=3, rc=rc)
srcArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=srcDistgrid, &
totallWidth=(/1,1/), totalUWidth=(/1,1/), indexflag=ESMF_INDEX_GLOBAL, &
distgridToArrayMap=(/1,2/), undistLBound=(/1/), undistUBound=(/2/), rc=rc)
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, rc=rc)
dstArray = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=dstDistgrid, &
distgridToArrayMap=(/2/), undistLBound=(/1/), undistUBound=(/4/), rc=rc)

Setting up factorList is identical to the previous cases since there is still only one value associated with each non-zero matrix element. However, each entry in factorIndexList now has 4 instead of just 2 components.

if (localPet == 0) then
allocate(factorList(1)) ! PET 0 specifies 1 factor
allocate(factorIndexList(4,1))
factorList = (/0.2/) ! factors
factorIndexList(1,:) = (/5/) ! seq indices into srcArray
factorIndexList(2,:) = (/1/) ! undistr. seq indices into srcArray
factorIndexList(3,:) = (/30/) ! seq indices into dstArray
factorIndexList(4,:) = (/2/) ! undistr. seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
dallocate(factorList)
dallocate(factorIndexList)
else if (localPet == 1) then
allocate(factorList(3)) ! PET 1 specifies 3 factor
allocate(factorIndexList(4,3))
factorList = (/0.5, 0.5, 0.8/) ! factors
factorIndexList(1,:) = (/8, 2, 12/) ! seq indices into srcArray
factorIndexList(2,:) = (/2, 1, 1/) ! undistr. seq indices into srcArray
factorIndexList(3,:) = (/11, 11, 30/) ! seq indices into dstArray
factorIndexList(4,:) = (/4, 4, 2/) ! undistr. seq indices into dstArray
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, factorList=factorList, &
factorIndexList=factorIndexList, rc=rc)
dallocate(factorList)
dallocate(factorIndexList)
else
! PETs 2 and 3 do not provide factors
call ESMF_ArraySMMStore(srcArray=srcArray, dstArray=dstArray, &
routehandle=sparseMatMulHandle, rc=rc)
endif
The call into the ESMF_ArraySMM() operation remains unchanged.

```fortran
   call ESMF_ArraySMM(srcArray=srcArray, dstArray=dstArray, &
                        routehandle=sparseMatMulHandle, rc=rc)
```

This operation will initialize the entire dstArray to 0.0 and then update two elements:

- **on DE 1:**
  \[ \text{dstArray}[4](2) = 0.5 \times \text{srcArray}(0,0)[1] + 0.5 \times \text{srcArray}(0,2)[2], \]

and

- **on DE 3:**
  \[ \text{dstArray}[2](1) = 0.2 \times \text{srcArray}(0,1)[1] + 0.8 \times \text{srcArray}(1,3)[1], \]

Here indices in () refer to distributed dimensions while indices in [] correspond to undistributed dimensions.

### 27.2.18 Communication – Scatter and Gather, revisited

The `ESMF_ArrayScatter()` and `ESMF_ArrayGather()` calls, introduced in section 27.2.13, provide a convenient way of communicating data between a Fortran array and all of the DEs of a single Array tile. A key requirement of `ESMF_ArrayScatter()` and `ESMF_ArrayGather()` is that the *shape* of the Fortran array and the Array tile must match. This means that the `dimCount` must be equal, and that the size of each dimension must match. Element reordering during scatter and gather is only supported on a per dimension level, based on the `decompflag` option available during DistGrid creation.

While the `ESMF_ArrayScatter()` and `ESMF_ArrayGather()` methods cover a broad, and important spectrum of cases, there are situations that require a different set of rules to scatter and gather data between a Fortran array and an ESMF Array object. For instance, it is often convenient to create an Array on a DistGrid that was created with arbitrary, user-supplied sequence indices. See section 34.3.6 for more background on DistGrids with arbitrary sequence indices.

```fortran
allocate(arbSeqIndexList(10)) ! each PET will have 10 elements

do i=1, 10
   arbSeqIndexList(i) = (i-1)*petCount + localPet+1 ! initialize unique seq. indices
enddo

distgrid = ESMF_DistGridCreate(arbSeqIndexList=arbSeqIndexList, rc=rc)

deallocate(arbSeqIndexList)

call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_I4, rank=1, rc=rc)

array = ESMF_ArrayCreate(arrayspec=arrayspec, distgrid=distgrid, rc=rc)
```
This array object holds 10 elements on each DE, and there is one DE per PET, for a total element count of 10 x petCount. The arbSeqIndexList, used during DistGrid creation, was constructed cyclic across all DEs. DE 0, for example, on a 4 PET run, would hold sequence indices 1, 5, 9, ... . DE 1 would hold 2, 6, 10, ..., and so on.

The usefulness of the user-specified arbitrary sequence indices becomes clear when they are interpreted as global element ids. The ArrayRedist() and ArraySMM() communication methods are based on sequence index mapping between source and destination Arrays. Other than providing a canonical sequence index order via the default sequence scheme, outlined in \[27.2.1\] ESMF does not place any restrictions on the sequence indices. Objects that were not created with user supplied sequence indices default to the ESMF sequence index order.

A common, and useful interpretation of the arbitrary sequence indices, specified during DistGrid creation, is that of relating them to the canonical ESMF sequence index order of another data object. Within this interpretation the array object created above could be viewed as an arbitrary distribution of a (petCount x 10) 2D array.

```fortran
if (localPet == 0) then
allocate(farray(petCount,10)) ! allocate 2D Fortran array petCount x 10
  do j=1, 10
    do i=1, petCount
      farray(i,j) = 100 + (j-1)*petCount + i ! initialize to something
    enddo
  enddo
else
allocate(farray(0,0)) ! must allocate an array of size 0 on all other PETs
endif
```

For a 4 PET run, `farray` on PET 0 now holds the following data.

```
---1----2----3------------10-----> j
| 1  101, 105, 109, ..... , 137
| 2  102, 106, 110, ..... , 138
| 3  103, 107, 111, ..... , 139
| 4  104, 108, 112, ..... , 140
v
i
```

On all other PETs `farray` has a zero size allocation.

Following the sequence index interpretation from above, scattering the data contained in `farray` on PET 0 across the array object created further up, seems like a well defined operation. Looking at it a bit closer, it becomes clear that it is in fact more of a redistribution than a simple scatter operation. The general rule for such a "redist-scatter" operation, of a Fortran array, located on a single PET, into an ESMF Array, is to use the canonical ESMF sequence index scheme to label the elements of the Fortran array, and to send the data to the Array element with the same sequence index.

The just described "redist-scatter" operation is much more general than the standard ESMF\_ArrayScatter() method. It does not require shape matching, and supports full element reordering based on the sequence indices. Before `farray` can be scattered across `array` in the described way, it must be wrapped into an ESMF Array object itself, essentially labeling the array elements according to the canonical sequence index scheme.
distgridAux = ESMF_DistGridCreate(minIndex=(/1,1/), &
maxIndex=(/petCount,10/), &
regDecomp=(/1,1/), rc=rc) ! DistGrid with only 1 DE

The first step is to create a DistGrid object with only a single DE. This DE must be located on the PET on which the Fortran data array resides. In this example farray holds data on PET 0, which is where the default DELayout will place the single DE defined in the DistGrid. If the farray was setup on a different PET, an explicit DELayout would need to be created first, mapping the only DE to the PET on which the data is defined.

Next the Array wrapper object can be created from the farray and the just created DistGrid object.

arrayAux = ESMF_ArrayCreate(farray=farray, distgrid=distgridAux, &
indexflag=ESMF_INDEX_DELOCAL, rc=rc)

At this point all of the pieces are in place to use ESMF_ArrayRedist() to do the "redist-scatter" operation. The typical store/execute/release pattern must be followed.

call ESMF_ArrayRedistStore(srcArray=arrayAux, dstArray=array, &
routehandle=scatterHandle, rc=rc)

call ESMF_ArrayRedist(srcArray=arrayAux, dstArray=array, &
routehandle=scatterHandle, rc=rc)

In this example, after ESMF_ArrayRedist() was called, the content of array on a 4 PET run would look like this:

<table>
<thead>
<tr>
<th>PET 0</th>
<th>PET 1</th>
<th>PET 2</th>
<th>PET 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>101, 105, 109, .., 137</td>
<td>102, 106, 110, .., 138</td>
<td>103, 107, 111, .., 139</td>
<td>104, 108, 112, .., 140</td>
</tr>
</tbody>
</table>

Once set up, scatterHandle can be used repeatedly to scatter data from farray on PET 0 to all the DEs of array. All of the resources should be released once scatterHandle is no longer needed.

call ESMF_ArrayRedistRelease(routehandle=scatterHandle, rc=rc)

The opposite operation, i.e. gathering of the array data into farray on PET 0, follows a very similar setup. In fact, the arrayAux object already constructed for the scatter direction, can directly be re-used. The only thing that is different for the "redist-gather", are the srcArray and dstArray argument assignments, reflecting the opposite direction of data movement.

call ESMF_ArrayRedistStore(srcArray=array, dstArray=arrayAux, &
routehandle=gatherHandle, rc=rc)
call ESMF_ArrayRedist(srcArray=array, dstArray=arrayAux, &
  routehandle=gatherHandle, rc=rc)

Just as for the scatter case, the gatherHandle can be used repeatedly to gather data from array into farray on PET 0. All of the resources should be released once gatherHandle is no longer needed.

call ESMF_ArrayRedistRelease(routehandle=gatherHandle, rc=rc)

Finally the wrapper Array arrayAux and the associated DistGrid object can also be destroyed.

call ESMF_ArrayDestroy(arrayAux, rc=rc)

call ESMF_DistGridDestroy(distgridAux, rc=rc)

Further, the primary data objects of this example must be deallocated and destroyed.

deallocate(farray)

call ESMF_ArrayDestroy(array, rc=rc)

call ESMF_DistGridDestroy(distgrid, rc=rc)

### 27.2.19 Non-blocking Communications

All ESMF_RouteHandle based communication methods, like ESMF_ArrayRedist(), ESMF_ArrayHalo() and ESMF_ArraySMM(), can be executed in blocking or non-blocking mode. The non-blocking feature is useful, for example, to overlap computation with communication, or to implement a more loosely synchronized inter-Component interaction scheme than is possible with the blocking communication mode.

Access to the non-blocking execution mode is provided uniformly across all RouteHandle based communication calls. Every such call contains the optional routesyncflag argument of type ESMF_RouteSync_Flag. Section 50.4 lists all of the valid settings for this flag.

It is an execution time decision to select whether to invoke a precomputed communication pattern, stored in a RouteHandle, in the blocking or non-blocking mode. Neither requires specifically precomputed RouteHandles - i.e. a RouteHandle is neither specifically blocking nor specifically non-blocking.

call ESMF_ArrayRedistStore(srcArray=srcArray, dstArray=dstArray, &
  routehandle=routehandle, rc=rc)

The returned RouteHandle routehandle can be used in blocking or non-blocking execution calls. The application is free to switch between both modes for the same RouteHandle.
By default `routesyncflag` is set to `ESMF_ROUTESYNC_BLOCKING` in all of the RouteHandle execution methods, and the behavior is that of the VM-wide collective communication calls described in the previous sections. In the blocking mode the user must assume that the communication call will not return until all PETs have exchanged the precomputed information. On the other hand, the user has no guarantee about the exact synchronization behavior, and it is unsafe to make specific assumptions. What is guaranteed in the blocking communication mode is that when the call returns on the local PET, all data exchanges associated with all local DEs have finished. This means that all in-bound data elements are valid and that all out-bound data elements can safely be overwritten by the user.

```fortran
   call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
                      routehandle=routehandle, routesyncflag=ESMF_ROUTESYNC_BLOCKING, rc=rc)
```

The same exchange pattern, that is encoded in `routehandle`, can be executed in non-blocking mode, simply by setting the appropriate `routesyncflag` when calling into `ESMF_ArrayRedist()`.

At first sight there are obvious similarities between the non-blocking RouteHandle based execution paradigm and the non-blocking message passing calls provided by MPI. However, there are significant differences in the behavior of the non-blocking point-to-point calls that MPI defines and the non-blocking mode of the collective exchange patterns described by ESMF RouteHandles.

Setting `routesyncflag` to `ESMF_ROUTESYNC_NBSTART` in any RouteHandle execution call returns immediately after all out-bound data has been moved into ESMF internal transfer buffers and the exchange has been initiated.

```fortran
   call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
                      routehandle=routehandle, routesyncflag=ESMF_ROUTESYNC_NBSTART, rc=rc)
```

Once a call with `routesyncflag = ESMF_ROUTESYNC_NBSTART` returns, it is safe to modify the out-bound data elements in the `srcArray` object. However, no guarantees are made for the in-bound data elements in `dstArray` at this phase of the non-blocking execution. It is unsafe to access these elements until the exchange has finished locally.

One way to ensure that the exchange has finished locally is to call with `routesyncflag` set to `ESMF_ROUTESYNC_NBWAITFINISH`.

```fortran
   call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
                      routehandle=routehandle, routesyncflag=ESMF_ROUTESYNC_NBWAITFINISH, rc=rc)
```

Calling with `routesyncflag = ESMF_ROUTESYNC_NBWAITFINISH` instructs the communication method to wait and block until the previously started exchange has finished, and has been processed locally according to the RouteHandle. Once the call returns, it is safe to access both in-bound and out-bound data elements in `dstArray` and `srcArray`, respectively.

Some situations require more flexibility than is provided by the `ESMF_ROUTESYNC_NBSTART` - `ESMF_ROUTESYNC_NBWAITFINISH` pair. For instance, a Component that needs to interact with several other Components, virtually simultaneously, would initiate several different exchanges with `ESMF_ROUTESYNC_NBSTART`. Calling with `ESMF_ROUTESYNC_NBWAITFINISH` for any of the outstanding exchanges may potentially block for a long time, lowering the throughput. In the worst case a dead lock situation may arise. Calling with `routesyncflag = ESMF_ROUTESYNC_NBTTESTFINISH` addresses this problem.

```fortran
   call ESMF_ArrayRedist(srcArray=srcArray, dstArray=dstArray, &
                      routehandle=routehandle, routesyncflag=ESMF_ROUTESYNC_NBTTESTFINISH, &
                      finishedflag=finishflag, rc=rc)
```
This call tests the locally outstanding data transfer operation in routehandle, and finishes the exchange as much as currently possible. It does not block until the entire exchange has finished locally, instead it returns immediately after one round of testing has been completed. The optional return argument finishedflag is set to .true. if the exchange is completely finished locally, and set to .false. otherwise.

The user code must decide, depending on the value of the returned finishedflag, whether additional calls are required to finish an outstanding non-blocking exchange. If so, it can be done by calling ESMF_ArrayRedist() repeatedly with ESMF_ROUTESYNC_NBTESTFINISH until finishedflag comes back with a value of .true.. Such a loop allows other pieces of user code to be executed between the calls. A call with ESMF_ROUTESYNC_NBWAITFINISH can alternatively be used to block until the exchange has locally finished.

**Noteworthy property.** It is allowable to invoke a RouteHandle based communication call with routesyncflag set to ESMF_ROUTESYNC_NBTESTFINISH or ESMF_ROUTESYNC_NBWAITFINISH on a specific RouteHandle without there being an outstanding non-blocking exchange. As a matter of fact, it is not required that there was ever a call made with ESMF_ROUTESYNC_NBBSTART for the RouteHandle. In these cases the calls made with ESMF_ROUTESYNC_NBTESTFINISH or ESMF_ROUTESYNC_NBWAITFINISH will simply return immediately (with finishedflag set to .true.).

**Noteworthy property.** It is fine to mix blocking and non-blocking invokations of the same RouteHandle based communication call across the PETs. This means that it is fine for some PETs to issue the call with ESMF_ROUTESYNC_NBBLOCKING (or using the default), while other PETs call the same communication call with ESMF_ROUTESYNC_NBBSTART.

**Noteworthy restriction.** A RouteHandle that is currently involved in an outstanding non-blocking exchange may not be used to start any further exchanges, neither blocking nor non-blocking. This restriction is independent of whether the newly started RouteHandle based exchange is made for the same or for different data objects.

### 27.3 Restrictions and Future Work

- **CAUTION:** Depending on the specific ESMF_ArrayCreate() entry point used during Array creation, certain Fortran operations are not supported on the Fortran array pointer farrayPtr, returned by ESMF_ArrayGet(). Only if the ESMF_ArrayCreate() from pointer variant was used, will the returned farrayPtr variable contain the original bounds information, and be suitable for the Fortran deallocate() call. This limitation is a direct consequence of the Fortran 95 standard relating to the passing of array arguments. Fortran array pointers returned from an Array that was created through the assumed shape array variant of ESMF_ArrayCreate() will have bounds that are consistent with the other arguments specified during Array creation. These pointers are not suitable for deallocation in accordance to the Fortran 95 standard.

- **1D limit:** ArrayHalo(), ArrayRedist() and ArraySMM() operations on Arrays created on DistGrids with arbitrary sequence indices are currently limited to 1D arbitrary DistGrids. There is no restriction on the number, size and mapping of undistributed Array dimensions in the presence of such a 1D arbitrary DistGrid.

### 27.4 Design and Implementation Notes

The Array class is part of the ESMF index space layer and is built ontop of the DistGrid and DELayout classes. The DELayout class introduces the notion of decomposition elements (DEs) and their layout across the available PETs. The DistGrid describes how index space is decomposed by assigning logically rectangular index space pieces or DE-local tiles to the DEs. The Array finally associates a local memory allocation with each local DE.

The following is a list of implementation specific details about the current ESMF Array.

- Implementation language is C++.
- Local memory allocations are internally held in ESMF_LocalArray objects.
• All precomputed communication methods are based on sparse matrix multiplication.

27.5 Class API

27.5.1 ESMF_ArrayAssignment(=) - Array assignment

INTERFACE:

```fortran
interface assignment (=)
    array1 = array2
end interface
```

ARGUMENTS:

```fortran
type(ESMF_Array) :: array1
type(ESMF_Array) :: array2
```

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign array1 as an alias to the same ESMF Array object in memory as array2. If array2 is invalid, then array1 will be equally invalid after the assignment.

The arguments are:

array1 The ESMF_Array object on the left hand side of the assignment.
array2 The ESMF_Array object on the right hand side of the assignment.

27.5.2 ESMF_ArrayOperator(==) - Array equality operator

INTERFACE:

```fortran
interface operator(==)
    if (array1 == array2) then ... endif
    OR
    result = (array1 == array2)
end interface
```

RETURN VALUE:

```fortran
logical :: result
```

ARGUMENTS:
type(ESMF_Array), intent(in) :: array1
type(ESMF_Array), intent(in) :: array2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether array1 and array2 are valid aliases to the same ESMF Array object in memory. For a more general comparison of two ESMF Arrays, going beyond the simple alias test, the ESMF_ArrayMatch() function (not yet implemented) must be used.

The arguments are:

array1 The ESMF_Array object on the left hand side of the equality operation.
array2 The ESMF_Array object on the right hand side of the equality operation.

---

27.5.3 ESMF_ArrayOperator(/=) - Array not equal operator

INTERFACE:

interface operator(/=)
  if (array1 /= array2) then ... endif
OR
  result = (array1 /= array2)
end interface

RETURN VALUE:

logical :: result

ARGUMENTS:

  type(ESMF_Array), intent(in) :: array1
  type(ESMF_Array), intent(in) :: array2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether array1 and array2 are not valid aliases to the same ESMF Array object in memory. For a more general comparison of two ESMF Arrays, going beyond the simple alias test, the ESMF_ArrayMatch() function (not yet implemented) must be used.

The arguments are:
The ESMF_Array object on the left hand side of the non-equality operation.

The ESMF_Array object on the right hand side of the non-equality operation.

27.5.4 ESMF_ArrayCopy - Copy data from one Array object to another

INTERFACE:

    subroutine ESMF_ArrayCopy(arrayOut, arrayIn, rc)

ARGUMENTS:

    type(ESMF_Array), intent(inout) :: arrayOut
    type(ESMF_Array), intent(in) :: arrayIn
    [rc] Return code; equals ESMF_SUCCESS if there are no errors.

DESCRIPTION:

Copy data from one ESMF_Array object to another.

The arguments are:

arrayOut ESMF_Array object into which to copy the data. The incoming arrayOut must already references a matching memory allocation.

arrayIn ESMF_Array object that holds the data to be copied.

27.5.5 ESMF_ArrayCreate - Create Array object from Fortran array pointer

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateFromPtr<rank><type><kind>(distgrid, farrayPtr, & datacopyflag, distgridToArrayMap, computationalEdgeLWidth, & computationalEdgeUWidth, computationalLWidth, & computationalUWidth, totalLWidth, & totalUWidth, name, rc)

RETURN VALUE:

    type(ESMF_Array) :: ESMF_ArrayCreateDataPtr<rank><type><kind>
ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: distgridToArrayMap(:)
integer, intent(in), optional :: computationalEdgeLWidth(:)
integer, intent(in), optional :: computationalEdgeUWidth(:)
integer, intent(in), optional :: computationalLWidth(:)
integer, intent(in), optional :: computationalUWidth(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object from existing local native Fortran arrays with pointer attribute. The decomposition and distribution is specified by the distgrid argument. Each PET must issue this call with identical arguments in order to create a consistent Array object. The only exception is the farrayPtr argument which will be different on each PET. The bounds of the local arrays are preserved by this call and determine the bounds of the total region of the resulting Array object. Bounds of the DE-local exclusive regions are set to be consistent with the total regions and the specified distgrid argument. Bounds for Array dimensions that are not distributed are automatically set to the bounds provided by farrayPtr.

This interface requires a 1 DE per PET decomposition. The Array object will not be created and an error will be returned if this condition is not met.

The not distributed Array dimensions form a tensor of rank = array.rank - distgrid.dimCount. The widths of the computational region are set to the provided value, or zero by default, for all tensor elements. Use ESMF_ArraySet() to change these default settings after the Array object has been created.

The return value is the newly created ESMF_Array object.

The arguments are:

distgrid ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank of farrayPtr.

farrayPtr Valid native Fortran array with pointer attribute. Memory must be associated with the actual argument. The type/kind/rank information of farrayPtr will be used to set Array's properties accordingly. The shape of farrayPtr will be checked against the information contained in the distgrid. The bounds of farrayPtr will be preserved by this call and the bounds of the resulting Array object are set accordingly.

[datacopyflag] Specifies whether the Array object will reference the memory allocation provided by farrayPtr directly or will copy the data from farrayPtr into a new memory allocation. For valid values see [50.12]. The default is ESMF_DATACOPY_REFERENCE. Note that the ESMF_DATACOPY_REFERENCE option may not be safe when providing an array slice in farrayPtr.
[distgridToArrayMap] List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in farrayPtr by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the farrayPtr argument in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped farrayPtr dimensions are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

[computationalEdgeLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for DEs that are located on the edge of a tile. The default is a zero vector.

[computationalEdgeUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for DEs that are located on the edge of a tile. The default is a zero vector.

[computationalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region. The default is a zero vector.

[computationalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region. The default is a zero vector.

[totalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the total memory region with respect to the lower corner of the exclusive region. The default is to accommodate the union of exclusive and computational region exactly.

[totalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the total memory region with respect to the upper corner of the exclusive region. The default is a vector that contains the remaining number of elements in each direction as to fit the union of exclusive and computational region into the memory region provided by the farrayPtr argument.

[name] Name of the Array object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.6 ESMF_ArrayCreate - Create Array object from Fortran array pointer w/ arbitrary seqIndices for halo

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateFromPtrArb<rank><type><kind><name>(distgrid, farrayPtr, &
haloSeqIndexList, keywordEnforcer datacopyflag, distgridToArrayMap, &
name, rc)

RETURN VALUE:
type(ESMF_Array) :: ESMF_ArrayCreateDataPtrArb<rank><type><kind>

ARGUMENTS:

 type(ESMF_DistGrid), intent(in) :: distgrid
 <type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
 integer, intent(in) :: haloSeqIndexList(:)
 -- The following arguments require argument keyword syntax (e.g. rc=rc). --
 type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
 integer, intent(in), optional :: distgridToArrayMap(:)
 character (len=*), intent(in), optional :: name
 integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object from existing local native Fortran arrays with pointer attribute, according to distgrid. Besides farrayPtr each PET must issue this call with identical arguments in order to create a consistent Array object. The bounds of the local arrays are preserved by this call and determine the bounds of the total region of the resulting Array object. Bounds of the DE-local exclusive regions are set to be consistent with the total regions and the specified distgrid argument. Bounds for Array dimensions that are not distributed are automatically set to the bounds provided by farrayPtr.

This interface requires a 1 DE per PET decomposition. The Array object will not be created and an error will be returned if this condition is not met.

The not distributed Array dimensions form a tensor of rank = array.rank - distgrid.dimCount. The widths of the computational region are set to the provided value, or zero by default, for all tensor elements. Use ESMF_ArraySet() to change these default settings after the Array object has been created.

The return value is the newly created ESMF_Array object.

The arguments are:

distgrid  ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dim-Count of distgrid must be smaller or equal to the rank of farrayPtr.

farrayPtr  Valid native Fortran array with pointer attribute. Memory must be associated with the actual argument. The type/kind/rank information of farrayPtr will be used to set Array’s properties accordingly. The shape of farrayPtr will be checked against the information contained in the distgrid. The bounds of farrayPtr will be preserved by this call and the bounds of the resulting Array object are set accordingly.

haloSeqIndexList  One dimensional array containing sequence indices of local halo region. The size (and content) of haloSeqIndexList can (and typically will) be different on each PET.

[datacopyflag] Specifies whether the Array object will reference the memory allocation provided by farrayPtr directly or will copy the data from farrayPtr into a new memory allocation. For valid values see [50.12]. The default is ESMF_DATACOPY_REFERENCE. Note that the ESMF_DATACOPY_REFERENCE option may not be safe when providing an array slice in farrayPtr.
List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in farrayPtr by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the farrayPtr argument in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped farrayPtr dimensions are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

Name of the Array object.

Return code; equals ESMF_SUCCESS if there are no errors.

27.5.7 ESMF_ArrayCreate - Create Array object from Fortran array

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateAssmdShape<rank><type><kind> (distgrid, farray, &
indexflag, datacopyflag, distgridToArrayMap, &
computationalEdgeLWidth, computationalEdgeUWidth, computationalLWidth, &
computationalUWidth, totalLWidth, &
totalUWidth, undistLBound, undistUBound, name, rc)

RETURN VALUE:

type(ESMF_Array) :: ESMF_ArrayCreateDataAssmdShape<rank><type><kind>

ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
<type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)
type(ESMF_Index_Flag), intent(in) :: indexflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: distgridToArrayMap(:)
integer, intent(in), optional :: computationalEdgeLWidth(:)
integer, intent(in), optional :: computationalEdgeUWidth(:)
integer, intent(in), optional :: computationalLWidth(:)
integer, intent(in), optional :: computationalUWidth(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(in), optional :: undistLBound(:)
integer, intent(in), optional :: undistUBound(:)
character (len=*) intent(in), optional :: name
integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object from an existing local native Fortran array. The decomposition and distribution is specified by the distgrid argument. Each PET must issue this call with identical arguments in order to create a consistent Array object. The only exception is the farray argument which will be different on each PET. The local arrays provided must be dimensioned according to the DE-local total region. Bounds of the exclusive regions are set as specified in the distgrid argument. Bounds for Array dimensions that are not distributed can be chosen freely using the undistLBound and undistUBound arguments.

This interface requires a 1 DE per PET decomposition. The Array object will not be created and an error will be returned if this condition is not met.

The not distributed Array dimensions form a tensor of rank = array.rank - distgrid.dimCount. The widths of the computational region are set to the provided value, or zero by default, for all tensor elements. Use ESMF_ArraySet() to change these default settings after the Array object has been created.

The return value is the newly created ESMF_Array object.

The arguments are:

- **distgrid** ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank of farray.

- **farray** Valid native Fortran array, i.e. memory must be associated with the actual argument. The type/kind/rank information of farray will be used to set Array's properties accordingly. The shape of farray will be checked against the information contained in the distgrid.

- **indexflag** Indicate how DE-local indices are defined. See section 50.25 for a list of valid indexflag options.

- **[datacopyflag]** Specifies whether the Array object will reference the memory allocation provided by farray directly or will copy the data from farray into a new memory allocation. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE. Note that the ESMF_DATACOPY_REFERENCE option may not be safe when providing an array slice in farray.

- **[distgridToArrayMap]** List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in farray by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the farray argument in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped farray dimensions are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

- **[computationalEdgeLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for DEs that are located on the edge of a tile. The default is a zero vector.

- **[computationalEdgeUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for DEs that are located on the edge of a tile. The default is a zero vector.
[computationalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region. The default is a zero vector.

[computationalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region. The default is a zero vector.

[totalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the total memory region with respect to the lower corner of the exclusive region. The default is to accommodate the union of exclusive and computational region exactly.

[totalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the total memory region with respect to the upper corner of the exclusive region. The default is a vector that contains the remaining number of elements in each direction as to fit the union of exclusive and computational region into the memory region provided by the farray argument.

[undistLBound] Lower bounds for the array dimensions that are not distributed. By default lbound is 1.

[undistUBound] Upper bounds for the array dimensions that are not distributed. By default ubound is equal to the extent of the corresponding dimension in farray.

[name] Name of the Array object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.8 ESMF_ArrayCreate - Create Array object from a list of LocalArray objects

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateLocalArray(distgrid, localArrayList, &
  indexflag, datacopyflag, distgridToArrayMap, computationalEdgeLWidth, &
  computationalEdgeUWidth, computationalLWidth, computationalUWidth, &
  totalLWidth, totalUWidth, undistLBound, undistUBound, name, rc)

RETURN VALUE:

  type(ESMF_Array) :: ESMF_ArrayCreateLocalArray

ARGUMENTS:

  type(ESMF_DistGrid), intent(in) :: distgrid
  type(ESMF_LocalArray), intent(in) :: localArrayList(:)
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_Index_Flag), intent(in), optional :: indexflag
  type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
  integer, intent(in), optional :: distgridToArrayMap(:)
  integer, intent(in), optional :: computationalEdgeLWidth(:)
  integer, intent(in), optional :: computationalEdgeUWidth(:)
  integer, intent(in), optional :: computationalLWidth(:)
  integer, intent(in), optional :: computationalUWidth(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(in), optional :: undistLBound(:)
integer, intent(in), optional :: undistUBound(:)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object from existing ESMF_LocalArray objects. The decomposition and distribution is specified by the distgrid argument. Each PET must issue this call with identical arguments in order to create a consistent Array object. The only exception is the localarrayList argument which will be different on each PET. The local arrays provided must be dimensioned according to the DE-local total region. Bounds of the exclusive regions are set as specified in the distgrid argument. Bounds for Array dimensions that are not distributed can be chosen freely using the undistLBound and undistUBound arguments.

This interface is able to handle multiple DEs per PET.

The not distributed Array dimensions form a tensor of rank = array.rank - distgrid.dimCount. The widths of the computational region are set to the provided value, or zero by default, for all tensor elements. Use ESMF_ArraySet() to change these default settings after the Array object has been created.

The return value is the newly created ESMF_Array object.

The arguments are:

- **distgrid** ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error will be raised.

- **localarrayList** List of valid ESMF_LocalArray objects, i.e. memory must be associated with the actual arguments. The type/kind/rank information of all localarrayList elements must be identical and will be used to set Array's properties accordingly. The shape of each localarrayList element will be checked against the information contained in the distgrid.

- **[indexflag]** Indicate how DE-local indices are defined. By default, the exclusive region of each DE is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated DistGrid. See section 50.25 for a list of valid indexflag options.

- **[datacopyflag]** Specifies whether the Array object will reference the memory allocation of the arrays provided in localarrayList directly, or will copy the actual data into new memory allocations. For valid values see 50.12. The default is ESMF_DATACOPY_REFERENCE.

- **[distgridToArrayMap]** List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in the localarrayList elements by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the localarrayList elements in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped dimensions in the localarrayList elements are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries
must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

**[computationalEdgeLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for DEs that are located on the edge of a tile.

**[computationalEdgeUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for DEs that are located on the edge of a tile.

**[computationalLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region. The default is a zero vector.

**[computationalUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region. The default is a zero vector.

**[totalLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the total memory region with respect to the lower corner of the exclusive region. The default is to accommodate the union of exclusive and computational region exactly.

**[totalUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the total memory region with respect to the upper corner of the exclusive region. The default is a vector that contains the remaining number of elements in each direction as to fit the union of exclusive and computational region into the memory region provided by the localarrayList argument.

**[undistLBound]** Lower bounds for the array dimensions that are not distributed. By default lbound is 1.

**[undistUBound]** Upper bounds for the array dimensions that are not distributed. By default ubound is equal to the extent of the corresponding dimension in localarrayList.

**[name]** Name of the Array object.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 27.5.9 ESMF_ArrayCreate - Create Array object from a list of LocalArray objects w/ arbitrary seqIndices for halo

**INTERFACE:**

```fortran
! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateLocalArrayArb(distgrid, localarrayList, &
haloSeqIndexList, datacopyflag, distgridToArrayMap, undistLBound, &
undistUBound, name, rc)
```

**RETURN VALUE:**

```
type(ESMF_Array) :: ESMF_ArrayCreateLocalArrayArb
```
ARGUMENTS:

\[
\begin{align*}
type(ESMF\_DistGrid), \text{intent(in)} :: \text{distgrid} \\
type(ESMF\_LocalArray), \text{intent(in)} :: \text{localarrayList}() \\
\text{integer, intent(in)} :: \text{haloSeqIndexList}() \\
\text{-- The following arguments require argument keyword syntax (e.g. rc=rc). --} \\
type(ESMF\_DataCopy\_Flag), \text{intent(in), optional} :: \text{datacopyflag} \\
\text{integer, intent(in), optional} :: \text{distgridToArrayMap}() \\
\text{integer, intent(in), optional} :: \text{undistLBound}() \\
\text{integer, intent(in), optional} :: \text{undistUBound}() \\
\text{character (len=*), intent(in), optional} :: \text{name} \\
\text{integer, intent(out), optional} :: \text{rc}
\end{align*}
\]

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object from existing ESMF_LocalArray objects according to distgrid. Each PET must issue this call in unison in order to create a consistent Array object. The local arrays provided must be dimensioned according to the DE-local total region. Bounds of the exclusive regions are set as specified in the distgrid argument. Bounds for array dimensions that are not distributed can be chosen freely using the undistLBound and undistUBound arguments.

The return value is the newly created ESMF_Array object.

The arguments are:

**distgrid** ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error will be raised.

**localarrayList** List of valid ESMF_LocalArray objects, i.e. memory must be associated with the actual arguments. The type/kind/rank information of all localarrayList elements must be identical and will be used to set Array's properties accordingly. The shape of each localarrayList element will be checked against the information contained in the distgrid.

**haloSeqIndexList** One dimensional array containing sequence indices of local halo region. The size (and content) of haloSeqIndexList can (and typically will) be different on each PET.

/datacopyflag/ Specifies whether the Array object will reference the memory allocation of the arrays provided in localarrayList directly, or will copy the actual data into new memory allocations. For valid values see [50.12](#). The default is ESMF_DATACOPY_REFERENCE.

/distgridToArrayMap/ List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in the localarrayList elements by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the localarrayList elements in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped dimensions in the localarrayList elements are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.
[undistLBound] Lower bounds for the array dimensions that are not distributed. By default lbound is 1.
[undistUBound] Upper bounds for the array dimensions that are not distributed. By default ubound is equal to the extent of the corresponding dimension in localarrayList.
[name] Name of the Array object.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.10  ESMF_ArrayCreate - Create Array object from typekind (allocate memory)

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateAllocate(distgrid, typekind, indexflag, &
  distgridToArrayMap, computationalEdgeLWidth, computationalEdgeUWidth, &
  computationalLWidth, computationalUWidth, totalLWidth, totalUWidth, &
  undistLBound, undistUBound, name, vm, rc)

RETURN VALUE:

type(ESMF_Array) :: ESMF_ArrayCreateAllocate

ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
type(ESMF_TypeKind_Flag), intent(in) :: typekind
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(in), optional :: distgridToArrayMap(:)
integer, intent(in), optional :: computationalEdgeLWidth(:)
integer, intent(in), optional :: computationalEdgeUWidth(:)
integer, intent(in), optional :: computationalLWidth(:)
integer, intent(in), optional :: computationalUWidth(:)
integer, intent(in), optional :: totalLWidth(:)
integer, intent(in), optional :: totalUWidth(:)
integer, intent(in), optional :: undistLBound(:)
integer, intent(in), optional :: undistUBound(:)
class (len=*) , intent(in), optional :: name
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.
Changes made after the 5.2.0r release:
6.3.0r Added argument `vm` to support object creation on a different VM than that of the current context.

DESCRIPTION:

Create an ESMF_Array object and allocate uninitialized data space according to typekind and distgrid. The Array rank is indirectly determined by the incoming information. Each PET must issue this call in unison in order to create a consistent Array object. DE-local allocations are made according to the total region defined by the distgrid and the optional `Width` arguments.

The return value is the newly created ESMF_Array object.

The arguments are:

- **distgrid** ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error will be raised.

- **typekind** The typekind of the Array.

- **[indexflag]** Indicate how DE-local indices are defined. By default, the exclusive region of each DE is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated DistGrid. See section 50.25 for a list of valid indexflag options.

- **[distgridToArrayMap]** List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in the newly allocated Array object by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the Array object in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped dimensions in the Array object are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

- **[computationalEdgeLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for DEs that are located on the edge of a tile.

- **[computationalEdgeUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for DEs that are located on the edge of a tile.

- **[computationalLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region. The default is a zero vector.

- **[computationalUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region. The default is a zero vector.

- **[totalLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the total memory region with respect to the lower corner of the exclusive region. The default is to accommodate the union of exclusive and computational region.

- **[totalUWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the total memory region with respect to the upper corner of the exclusive region. The default is to accommodate the union of exclusive and computational region.
Lower bounds for the array dimensions that are not distributed.

Upper bounds for the array dimensions that are not distributed.

Name of the Array object.

If present, the Array object is created on the specified ESMF_VM object. The default is to create on the VM of the current context.

Return code; equals ESMF_SUCCESS if there are no errors.

27.5.11 ESMF_ArrayCreate - Create Array object from typekind (allocate memory) w/ arbitrary seqIndices for halo

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateAllocateArb(distgrid, typekind, &
haloSeqIndexList, distgridToArrayMap, &
undistLBound, undistUBound, name, rc)

RETURN VALUE:

type(ESMF_Array) :: ESMF_ArrayCreateAllocateArb

ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
type(ESMF_TypeKind_Flag), intent(in) :: typekind
integer, intent(in) :: haloSeqIndexList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: distgridToArrayMap(:)
integer, intent(in), optional :: undistLBound(:)
integer, intent(in), optional :: undistUBound(:)
character (len=*) :: name
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object and allocate uninitialized data space according to typekind and distgrid. The Array rank is indirectly determined by the incoming information. Each PET must issue this call in unison in order to create a consistent Array object. DE-local allocations are made according to the total region defined by the distgrid and haloSeqIndexList arguments.

The return value is the newly created ESMF_Array object.

The arguments are:
distgrid  ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dim-
Count of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error
will be raised.

typekind  The typekind of the Array.

haloSeqIndexList  One dimensional array containing sequence indices of local halo region. The size (and content) of
haloSeqIndexList can (and typically will) be different on each PET.

[distgridToArrayMap]  List that contains as many elements as is indicated by distgrid's dimCount. The list
elements map each dimension of the DistGrid object to a dimension in the newly allocated Array object by
specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against
the lower dimensions of the Array object in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped
dimensions in the Array object are not decomposed dimensions and form a tensor of rank = Array.
rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and
smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is
zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain
zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that
the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

[undistLBound]  Lower bounds for the array dimensions that are not distributed.

[undistUBound]  Upper bounds for the array dimensions that are not distributed.

[name]  Name of the Array object.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.12  ESMF_ArrayCreate - Create Array object from ArraySpec (allocate memory)

INTERFACE:

Changes made after the 5.2.0r release:

6.3.0r Added argument vm to support object creation on a different VM than that of the current context.

DESCRIPTION:

Create an ESMF_Array object and allocate uninitialized data space according to arrayspec and distgrid. Each PET must issue this call with identical arguments in order to create a consistent Array object. DE-local allocations are made according to the total region defined by the arguments to this call: distgrid and the optional Width arguments.

The return value is the newly created ESMF_Array object.

The arguments are:

**distgrid** ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dimCount of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error will be raised.

**arrayspec** ESMF_ArraySpec object containing the type/kind/rank information.

**[indexflag]** Indicate how DE-local indices are defined. By default, the exclusive region of each DE is placed to start at the local index space origin, i.e. (1, 1, ..., 1). Alternatively the DE-local index space can be aligned with the global index space, if a global index space is well defined by the associated DistGrid. See section 50.25 for a list of valid indexflag options.

**[distgridToArrayMap]** List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in the newly allocated Array object by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the Array object in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped dimensions in the Array object are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

**[computationalEdgeLWidth]** This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for DEs that are located on the edge of a tile.
[computationalEdgeUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for DEs that are located on the edge of a tile.

[computationalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the computational region with respect to the lower corner of the exclusive region. The default is a zero vector.

[computationalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the computational region with respect to the upper corner of the exclusive region. The default is a zero vector.

[totalLWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the lower corner of the total memory region with respect to the lower corner of the exclusive region. The default is to accommodate the union of exclusive and computational region.

[totalUWidth] This vector argument must have dimCount elements, where dimCount is specified in distgrid. It specifies the upper corner of the total memory region with respect to the upper corner of the exclusive region. The default is to accommodate the union of exclusive and computational region.

[undistLBound] Lower bounds for the array dimensions that are not distributed.

[undistUBound] Upper bounds for the array dimensions that are not distributed.

[name] Name of the Array object.

[vm] If present, the Array object is created on the specified ESMF_VM object. The default is to create on the VM of the current context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.13 ESMF_ArrayCreate - Create Array object from ArraySpec (allocate memory) w/ arbitrary seqIndices for halo

INTERFACE:

! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateAllocateASArb(distgrid, arrayspec, &
   haloSeqIndexList, distgridToArrayMap, &
   undistLBound, undistUBound, name, rc)

RETURN VALUE:

type(ESMF_Array) :: ESMF_ArrayCreateAllocateASArb

ARGUMENTS:

   type(ESMF_DistGrid), intent(in) :: distgrid
   type(ESMF_ArraySpec), intent(in) :: arrayspec
   integer, intent(in) :: haloSeqIndexList(:)
   -- The following arguments require argument keyword syntax (e.g. rc=rc).
   -- integer, intent(in), optional :: distgridToArrayMap(:)
integer, intent(in), optional :: undistLBound(:)
integer, intent(in), optional :: undistUBound(:)
caracter (len=*
, intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object and allocate uninitialized data space according to arrayspec and distgrid. Each PET must issue this call in unison in order to create a consistent Array object. DE-local allocations are made according to the total region defined by the arguments to this call: distgrid and haloSeqIndexList arguments.

The return value is the newly created ESMF_Array object.

The arguments are:

distgrid ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs. The dim-Count of distgrid must be smaller or equal to the rank specified in arrayspec, otherwise a runtime ESMF error will be raised.

arrayspec ESMF_ArraySpec object containing the type/kind/rank information.

haloSeqIndexList One dimensional array containing sequence indices of local halo region. The size (and content) of haloSeqIndexList can (and typically will) be different on each PET.

[distgridToArrayMap] List that contains as many elements as is indicated by distgrid's dimCount. The list elements map each dimension of the DistGrid object to a dimension in the newly allocated Array object by specifying the appropriate Array dimension index. The default is to map all of distgrid's dimensions against the lower dimensions of the Array object in sequence, i.e. distgridToArrayMap = (/1, 2, .../). Unmapped dimensions in the Array object are not decomposed dimensions and form a tensor of rank = Array.rank - DistGrid.dimCount. All distgridToArrayMap entries must be greater than or equal to zero and smaller than or equal to the Array rank. It is erroneous to specify the same entry multiple times unless it is zero. If the Array rank is less than the DistGrid dimCount then the default distgridToArrayMap will contain zeros for the dimCount - rank rightmost entries. A zero entry in the distgridToArrayMap indicates that the particular DistGrid dimension will be replicating the Array across the DEs along this direction.

[undistLBound] Lower bounds for the array dimensions that are not distributed.

[undistUBound] Upper bounds for the array dimensions that are not distributed.

[name] Name of the Array object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.14 ESMF_ArrayCreate - Create Array object as copy of existing Array object

INTERFACE:
! Private name; call using ESMF_ArrayCreate()
function ESMF_ArrayCreateCopy(array, rc)

RETURN VALUE:

type(ESMF_Array) :: ESMF_ArrayCreateCopy

ARGUMENTS:

type(ESMF_Array), intent(in) :: array
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_Array object as the copy of an existing Array.
The return value is the newly created ESMF_Array object.
The arguments are:

array ESMF_Array object to be copied.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.15 ESMF_ArrayDestroy - Release resources associated with an Array object

INTERFACE:

subroutine ESMF_ArrayDestroy(array, rc)

ARGUMENTS:

type(ESMF_Array), intent(inout) :: array
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Destroy an ESMF_Array, releasing the resources associated with the object.

The arguments are:

array  ESMF_Array object to be destroyed.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.16  ESMF_ArrayGather - Gather a Fortran array from an ESMF_Array

INTERFACE:

subroutine ESMF_ArrayGather(array, farray, rootPet, tile, vm, rc)

ARGUMENTS:

type(ESMF_Array), intent(in) :: array
<type>(ESMF_KIND_<kind>), intent(out), target :: farray(<rank>)
integer, intent(in) :: rootPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: tile
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gather the data of an ESMF_Array object into the farray located on rootPET. A single DistGrid tile of array must be gathered into farray. The optional tile argument allows selection of the tile. For Arrays defined on a single tile DistGrid the default selection (tile 1) will be correct. The shape of farray must match the shape of the tile in Array.

If the Array contains replicating DistGrid dimensions data will be gathered from the numerically higher DEs. Replicated data elements in numerically lower DEs will be ignored.

This version of the interface implements the PET-based blocking paradigm: Each PET of the VM must issue this call exactly once for all of its DEs. The call will block until all PET-local data objects are accessible.

The arguments are:

array  The ESMF_Array object from which data will be gathered.
The Fortran array into which to gather data. Only root must provide a valid `farray`, the other PETs may treat `farray` as an optional argument.

**rootPet** PET that holds the valid destination array, i.e. `farray`.

**[tile]** The DistGrid tile in `array` from which to gather `farray`. By default `farray` will be gathered from tile 1.

**[vm]** Optional `ESMF_VM` object of the current context. Providing the VM of the current context will lower the method's overhead.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

---

### 27.5.17 ESMF_ArrayGet - Get object-wide Array information

**INTERFACE:**

```fortran
! Private name; call using ESMF_ArrayGet()
subroutine ESMF_ArrayGetDefault(array, arrayspec, typekind, &
  rank, localarrayList, indexflag, distgridToArrayMap, &
  distgridToPackedArrayMap, arrayToDistGridMap, undistLBound, &

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.2.0rp1 Added argument localDeToDeMap. Started to deprecate argument localDeList. The new argument name correctly uses the Map suffix and better describes the returned information. This was pointed out by user request.

DESCRIPTION:

Get internal information.

This interface works for any number of DEs per PET.

The arguments are:

array Queried ESMF_Array object.
[arrayspec] ESMF_ArraySpec object containing the type/kind/rank information of the Array object.
[typekind] TypeKind of the Array object.
[rank] Rank of the Array object.
[localarrayList] Upon return this holds a list of the associated ESMC_LocalArray objects. localarrayList must be allocated to be of size localDeCount, i.e. the number of DEs associated with the calling PET.
[indexflag] Upon return this flag indicates how the DE-local indices are defined. See section 50.25 for a list of possible return values.
[distgridToArrayMap] Upon return this list holds the Array dimensions against which the DistGrid dimensions are mapped. distgridToArrayMap must be allocated to be of size dimCount. An entry of zero indicates that the respective DistGrid dimension is replicating the Array across the DEs along this direction.
[distgridToPackedArrayMap] Upon return this list holds the indices of the Array dimensions in packed format against which the DistGrid dimensions are mapped. distgridToPackedArrayMap must be allocated to be of size dimCount. An entry of zero indicates that the respective DistGrid dimension is replicating the Array across the DEs along this direction.

[arrayToDistGridMap] Upon return this list holds the DistGrid dimensions against which the Array dimensions are mapped. arrayToDistGridMap must be allocated to be of size rank. An entry of zero indicates that the respective Array dimension is not decomposed, rendering it a tensor dimension.

[undistLBound] Upon return this array holds the lower bounds of the undistributed dimensions of the Array. UndistLBound must be allocated to be of size rank-dimCount.

[undistUBound] Upon return this array holds the upper bounds of the undistributed dimensions of the Array. UndistUBound must be allocated to be of size rank-dimCount.

[exclusiveLBound] Upon return this holds the lower bounds of the exclusive regions for all PET-local DEs. exclusiveLBound must be allocated to be of size (dimCount, localDeCount).

[exclusiveUBound] Upon return this holds the upper bounds of the exclusive regions for all PET-local DEs. exclusiveUBound must be allocated to be of size (dimCount, localDeCount).

[computationalLBound] Upon return this holds the lower bounds of the computational regions for all PET-local DEs. computationalLBound must be allocated to be of size (dimCount, localDeCount).

[computationalUBound] Upon return this holds the upper bounds of the computational regions for all PET-local DEs. computationalUBound must be allocated to be of size (dimCount, localDeCount).

[totalLBound] Upon return this holds the lower bounds of the total regions for all PET-local DEs. totalLBound must be allocated to be of size (dimCount, localDeCount).

[totalUBound] Upon return this holds the upper bounds of the total regions for all PET-local DEs. totalUBound must be allocated to be of size (dimCount, localDeCount).

[computationalLWidth] Upon return this holds the lower width of the computational regions for all PET-local DEs. computationalLWidth must be allocated to be of size (dimCount, localDeCount).

[computationalUWidth] Upon return this holds the upper width of the computational regions for all PET-local DEs. computationalUWidth must be allocated to be of size (dimCount, localDeCount).

[totalLWidth] Upon return this holds the lower width of the total memory regions for all PET-local DEs. totalLWidth must be allocated to be of size (dimCount, localDeCount).

[totalUWidth] Upon return this holds the upper width of the total memory regions for all PET-local DEs. totalUWidth must be allocated to be of size (dimCount, localDeCount).

[distgrid] Upon return this holds the associated ESMF_DistGrid object.

[dimCount] Number of dimensions (rank) of distgrid.

[tileCount] Number of tiles in distgrid.

[minIndexPTile] Lower index space corner per dim, per tile, with size(minIndexPTile) == (/dimCount, tileCount/).

[maxIndexPTile] Upper index space corner per dim, per tile, with size(maxIndexPTile) == (/dimCount, tileCount/).

[deToTileMap] List of tile id numbers, one for each DE, with size(deToTileMap) == (/deCount/)

[indexCountPDe] Array of extents per dim, per de, with size(indexCountPDe) == (/dimCount, deCount/).
The associated ESMF_DELayout object.

The total number of DEs in the Array.

The number of DEs in the Array associated with the local PET.

Mapping between localDe indices and the (global) DEs associated with the local PET. The localDe index variables are discussed in sections 27.5.2 and 27.2.5. The provided actual argument must be of size localDeCount.

DEPRECATED ARGUMENT! Please use the argument localDeToDeMap instead.

Name of the Array object.

Return code; equals ESMF_SUCCESS if there are no errors.

---

27.5.18 ESMF_ArrayGet - Get DE-local Array information for a specific dimension

INTERFACE:

! Private name; call using ESMF_ArrayGet()
subroutine ESMF_ArrayGetPLocalDePDim(array, dim, localDe, &
  indexCount, indexList, rc)

ARGUMENTS:

type(ESMF_Array), intent(in) :: array
integer, intent(in) :: dim
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: localDe
  integer, intent(out), optional :: indexCount
  integer, intent(out), optional :: indexList(:)
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get internal information per local DE, per dim.

This interface works for any number of DEs per PET.

The arguments are:

array Queried ESMF_Array object.

dim Dimension for which information is requested. [1,..,dimCount]

515
[localDe] Local DE for which information is requested. \([0, \ldots, \text{localDeCount}-1]\). For \text{localDeCount}=1 the \text{localDe} argument may be omitted, in which case it will default to \text{localDe}=0.

[indexCount] DistGrid indexCount associated with \text{localDe}, \text{dim}.

[indexList] List of DistGrid tile-local indices for \text{localDe} along dimension \text{dim}.

[rc] Return code; equals \text{ESMF_SUCCESS} if there are no errors.

---

27.5.19 ESMF_ArrayGet - Get a DE-local Fortran array pointer from an Array

INTERFACE:

\begin{verbatim}
! Private name; call using ESMF_ArrayGet()
subroutine ESMF_ArrayGetFPtr<rank><type><kind>(array, localDe, &
farrayPtr, rc)
\end{verbatim}

ARGUMENTS:

\begin{verbatim}
type(ESMF_Array), intent(in) :: array
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: localDe
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)
integer, intent(out), optional :: rc
\end{verbatim}

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Access Fortran array pointer to the specified DE-local memory allocation of the Array object.

The arguments are:

array Queried \text{ESMF_Array} object.

[localDe] Local DE for which information is requested. \([0, \ldots, \text{localDeCount}-1]\). For \text{localDeCount}=1 the \text{localDe} argument may be omitted, in which case it will default to \text{localDe}=0.

farrayPtr Upon return, \text{farrayPtr} points to the DE-local data allocation of \text{localDe} in \text{array}. It depends on the specific entry point of \text{ESMF_ArrayCreate()} used during \text{array} creation, which Fortran operations are supported on the returned \text{farrayPtr}. See \S7.3 for more details.

[rc] Return code; equals \text{ESMF_SUCCESS} if there are no errors.
27.5.20  ESMF_ArrayGet - Get a DE-local LocalArray object from an Array

INTERFACE:

! Private name; call using ESMF_ArrayGet()
subroutine ESMF_ArrayGetLocalArray(array, localDe, localarray, rc)

ARGUMENTS:

type(ESMF_Array), intent(in) :: array
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: localDe

type(ESMF_LocalArray), intent(inout) :: localarray
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Provide access to ESMF_LocalArray object that holds data for the specified local DE.

The arguments are:

array  Queried ESMF_Array object.

[localDe]  Local DE for which information is requested. [0,...,localDeCount-1]. For localDeCount==1 the localDe argument may be omitted, in which case it will default to localDe=0.

localarray  Upon return localarray refers to the DE-local data allocation of array.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.21  ESMF_ArrayHalo - Execute an Array halo operation

INTERFACE:

subroutine ESMF_ArrayHalo(array, routehandle, &
  routesyncflag, finishedflag, cancelledflag, checkflag, rc)

ARGUMENTS:

type(ESMF_Array), intent(inout) :: array

type(ESMF_RouteHandle), intent(inout) :: routehandle
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_RouteSync_Flag), intent(in), optional :: routesyncflag
logical, intent(out), optional :: finishedflag
logical, intent(out), optional :: cancelledflag
logical, intent(in), optional :: checkflag
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Execute a precomputed Array halo operation for array. The array argument must be weakly congruent and typekind conform to the Array used during ESMF_ArrayHaloStore(). Congruent Arrays possess matching Dist-Grids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

See ESMF_ArrayHaloStore() on how to precompute routehandle.

This call is collective across the current VM.

array ESMF_Array containing data to be haloed.

routehandle Handle to the precomputed Route.

[routesyncflag] Indicate communication option. Default is ESMF_ROUTESYNC_BLOCKING, resulting in a blocking operation. See section 50.44 for a complete list of valid settings.

[finishedflag] Used in combination with routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH. Returned finishedflag equal to .true. indicates that all operations have finished. A value of .false. indicates that there are still unfinished operations that require additional calls with routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH, or a final call with routesyncflag = ESMF_ROUTESYNC_NBWAITFINISH. For all other routesyncflag settings the returned value in finishedflag is always .true..

[cancelledflag] A value of .true. indicates that were cancelled communication operations. In this case the data in the dstArray must be considered invalid. It may have been partially modified by the call. A value of .false. indicates that none of the communication operations was cancelled. The data in dstArray is valid if finishedflag returns equal .true..

[checkflag] If set to .TRUE. the input Array pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.22 ESMF_ArrayHaloRelease - Release resources associated with Array halo operation

INTERFACE:
subroutine ESMF_ArrayHaloRelease(routehandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an Array halo operation. After this call routehandle becomes invalid.

routehandle  Handle to the precomputed Route.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.23  ESMF_ArrayHaloStore - Precompute an Array halo operation

INTERFACE:

subroutine ESMF_ArrayHaloStore(array, routehandle, &
    startregion, haloLDepth, haloUDepth, pipelineDepth, rc)

ARGUMENTS:

    type(ESMF_Array), intent(inout) :: array
    type(ESMF_RouteHandle), intent(inout) :: routehandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_StartRegion_Flag), intent(in), optional :: startregion
    integer, intent(in), optional :: haloLDepth(:)
    integer, intent(in), optional :: haloUDepth(:)
    integer, intent(inout), optional :: pipelineDepth
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release. Changes made after the 5.2.0r release:
6.1.0 Added argument pipelineDepth. The new argument provide access to the tuning parameter affecting the sparse matrix execution.

DESCRIPTION:

Store an Array halo operation over the data in array. By default, i.e. without specifying startregion, haloLDepth and haloUDepth, all elements in the total Array region that lie outside the exclusive region will be considered potential destination elements for halo. However, only those elements that have a corresponding halo source element, i.e. an exclusive element on one of the DEs, will be updated under the halo operation. Elements that have no associated source remain unchanged under halo.

Specifying startregion allows to change the shape of the effective halo region from the inside. Setting this flag to ESMF_STARTREGION_COMPUTATIONAL means that only elements outside the computational region of the Array are considered for potential destination elements for halo. The default is ESMF_STARTREGION_EXCLUSIVE.

The haloLDepth and haloUDepth arguments allow to reduce the extent of the effective halo region. Starting at the region specified by startregion, the haloLDepth and haloUDepth define a halo depth in each direction. Note that the maximum halo region is limited by the total Array region, independent of the actual haloLDepth and haloUDepth setting. The total Array region is local DE specific. The haloLDepth and haloUDepth are interpreted as the maximum desired extent, reducing the potentially larger region available for halo.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayHalo() on any Array that is weakly congruent and typekind conform to array. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

array ESMF_Array containing data to be haloed. The data in the halo region may be destroyed by this call.

routehandle Handle to the precomputed Route.

[startregion] The start of the effective halo region on every DE. The default setting is ESMF_STARTREGION_EXCLUSIVE, rendering all non-exclusive elements potential halo destination elements. See section 50.47 for a complete list of valid settings.

[haloLDepth] This vector specifies the lower corner of the effective halo region with respect to the lower corner of startregion. The size of haloLDepth must equal the number of distributed Array dimensions.

[haloUDepth] This vector specifies the upper corner of the effective halo region with respect to the upper corner of startregion. The size of haloUDepth must equal the number of distributed Array dimensions.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstanding during a halo exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the restuls. However, it may affect the performance reproducibility of the exchange.

The ESMF_ArraySMMStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( > 0 \) is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified on return. If the provided argument is \( < 0 \), the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.
27.5.24  ESMF_ArrayPrint - Print Array information

INTERFACE:

    subroutine ESMF_ArrayPrint(array, rc)

ARGUMENTS:

    type(ESMF_Array), intent(in) :: array
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Print internal information of the specified ESMF_Array object.

The arguments are:

array  ESMF_Array object.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.25  ESMF_ArrayRead - Read Array data from a file

INTERFACE:

    subroutine ESMF_ArrayRead(array, file, variableName, &
                              timeslice, iofmt, rc)
    ! We need to terminate the strings on the way to C++

ARGUMENTS:

    type(ESMF_Array), intent(inout) :: array
    character(*) , intent(in) :: file
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(*), intent(in), optional :: variableName
    integer, intent(in), optional :: timeslice
    type(ESMF_IOFmt_Flag), intent(in), optional :: iofmt
    integer, intent(out), optional :: rc
DESCRIPTION:

Read Array data from file and put it into an ESMF_Array object. For this API to be functional, the environment variable ESMF_PIO should be set to "internal" when the ESMF library is built. Please see the section on Data I/O, [46.3](#).

Limitations:

- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

array  The ESMF_Array object in which the read data is returned.

file  The name of the file from which Array data is read.

[variableName] Variable name in the file; default is the "name" of Array. Use this argument only in the IO format (such as NetCDF) that supports variable name. If the IO format does not support this (such as binary format), ESMF will return an error code.

[timeslice] The time-slice number of the variable read from file.

[iofmt] The IO format. Please see Section [50.26](#) for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.26 ESMF_ArrayRedist - Execute an Array redistribution

INTERFACE:

```fortran
subroutine ESMF_ArrayRedist(srcArray, dstArray, routehandle, &
routesyncflag, finishedflag, cancelledflag, checkflag, rc)
```

ARGUMENTS:

- type(ESMF_Array), intent(in), optional :: srcArray
- type(ESMF_Array), intent(inout), optional :: dstArray
- type(ESMF_RouteHandle), intent(inout) :: routehandle
- type(ESMF_RouteSync_Flag), intent(in), optional :: routesyncflag
- logical, intent(out), optional :: finishedflag
- logical, intent(out), optional :: cancelledflag
- logical, intent(in), optional :: checkflag
- integer, intent(out), optional :: rc

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Execute a precomputed Array redistribution from srcArray to dstArray. Both srcArray and dstArray must be weakly congruent and typekind conform with the respectives used during ESMF_ArrayRedistStore(). Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

The srcArray and dstArray arguments are optional in support of the situation where srcArray and/or dstArray are not defined on all PETs. The srcArray and dstArray must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical Array object for srcArray and dstArray arguments.

See ESMF_ArrayRedistStore() on how to precompute routehandle.

This call is collective across the current VM.

[srcArray] ESMF_Array with source data.

[dstArray] ESMF_Array with destination data.

routehandle Handle to the precomputed Route.

[routesyncflag] Indicate communication option. Default is ESMF_ROUTESYNC_BLOCKING, resulting in a blocking operation. See section for a complete list of valid settings.

[finishedflag] Used in combination with routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH. Returned finishedflag equal to .true. indicates that all operations have finished. A value of .false. indicates that there are still unfinished operations that require additional calls with routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH, or a final call with routesyncflag = ESMF_ROUTESYNC_NBWAITFINISH. For all other routesyncflag settings the returned value in finishedflag is always .true..

[cancelledflag] A value of .true. indicates that were cancelled communication operations. In this case the data in the dstArray must be considered invalid. It may have been partially modified by the call. A value of .false. indicates that none of the communication operations was cancelled. The data in dstArray is valid if finishedflag returns equal .true..

[checkflag] If set to .TRUE. the input Array pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.27 ESMF_ArrayRedistRelease - Release resources associated with Array redistribution

INTERFACE:
subroutine ESMF_ArrayRedistRelease(routehandle, rc)

ARGUMENTS:

  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an Array redistribution. After this call routehandle becomes invalid.

routehandle Handle to the precomputed Route.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.28 ESMF_ArrayRedistStore - Precompute Array redistribution with local factor argument

INTERFACE:

! Private name; call using ESMF_ArrayRedistStore()
subroutine ESMF_ArrayRedistStore<type><kind>(srcArray, dstArray, &
  routehandle, factor, srcToDstTransposeMap, &
  pipelineDepth, rc)

ARGUMENTS:

  type(ESMF_Array), intent(in) :: srcArray
  type(ESMF_Array), intent(inout) :: dstArray
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  <type>(ESMF_KIND_<kind>), intent(in) :: factor
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: srcToDstTransposeMap():
  integer, intent(inout), optional :: pipelineDepth
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added argument pipelineDepth. The new argument provide access to the tuning parameter affecting the sparse matrix execution.

DESCRIPTION:

ESMF_ArrayRedistStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_ArrayRedistStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_ArrayRedistStore() method, as provided through the separate entry points shown in 27.5.28 and 27.5.29 is described in the following paragraphs as a whole.

Store an Array redistribution operation from srcArray to dstArray. Interface 27.5.28 allows PETs to specify a factor argument. PETs not specifying a factor argument call into interface 27.5.29. If multiple PETs specify the factor argument, its type and kind, as well as its value must match across all PETs. If none of the PETs specify a factor argument the default will be a factor of 1. The resulting factor is applied to all of the source data during redistribution, allowing scaling of the data, e.g. for unit transformation.

Source Array, destination Array, and the factor may be of different <type><kind>. Further, source and destination Arrays may differ in shape, however, the number of elements must match.

If srcToDstTransposeMap is not specified the redistribution corresponds to an identity mapping of the sequentialized source Array to the sequentialized destination Array. If the srcToDstTransposeMap argument is provided it must be identical on all PETs. The srcToDstTransposeMap allows source and destination Array dimensions to be transposed during the redistribution. The number of source and destination Array dimensions must be equal under this condition and the size of mapped dimensions must match.

It is erroneous to specify the identical Array object for srcArray and dstArray arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayRedist() on any pair of Arrays that are weakly congruent and typekind conform with the srcArray, dstArray pair. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

srcArray ESMF_Array with source data.

dstArray ESMF_Array with destination data. The data in this Array may be destroyed by this call.

routehandle Handle to the precomputed Route.

factor Factor by which to multiply source data.
List with as many entries as there are dimensions in srcArray. Each entry maps the corresponding srcArray dimension against the specified dstArray dimension. Mixing of distributed and undistributed dimensions is supported.

The pipelineDepth parameter controls how many messages a PET may have outstanding during a redist exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

The ESMF_ArraySMMStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified on return. If the provided argument is \(< 0\), the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

Return code; equals ESMF_SUCCESS if there are no errors.

### 27.5.29 ESMF_ArrayRedistStore - Precompute Array redistribution without local factor argument

INTERFACE:

```fortran
! Private name; call using ESMF_ArrayRedistStore()
subroutine ESMF_ArrayRedistStoreNF(srcArray, dstArray, routehandle, &
                                   srcToDstTransposeMap, pipelineDepth, rc)
ARGUMENTS:

  type(ESMF_Array), intent(in) :: srcArray
  type(ESMF_Array), intent(inout) :: dstArray
  type(ESMF_RouteHandle), intent(inout) :: routehandle
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: srcToDstTransposeMap(:)
  integer, intent(inout), optional :: pipelineDepth
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

- **6.1.0** Added argument pipelineDepth. The new argument provide access to the tuning parameter affecting the sparse matrix execution.
DESCRIPTION:

ESMF_ArrayRedistStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_ArrayRedistStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_ArrayRedistStore() method, as provided through the separate entry points shown in 27.5.28 and 27.5.29 is described in the following paragraphs as a whole.

Store an Array redistribution operation from srcArray to dstArray. Interface 27.5.28 allows PETs to specify a factor argument. PETs not specifying a factor argument call into interface 27.5.29. If multiple PETs specify the factor argument, its type and kind, as well as its value must match across all PETs. If none of the PETs specify a factor argument the default will be a factor of 1. The resulting factor is applied to all of the source data during redistribution, allowing scaling of the data, e.g. for unit transformation.

Both srcArray and dstArray are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices.

Source Array, destination Array, and the factor may be of different <type><kind>. Further, source and destination Arrays may differ in shape, however, the number of elements must match.

If srcToDstTransposeMap is not specified the redistribution corresponds to an identity mapping of the sequentialized source Array to the sequentialized destination Array. If the srcToDstTransposeMap argument is provided it must be identical on all PETs. The srcToDstTransposeMap allows source and destination Array dimensions to be transposed during the redistribution. The number of source and destination Array dimensions must be equal under this condition and the size of mapped dimensions must match.

It is erroneous to specify the identical Array object for srcArray and dstArray arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArrayRedist() on any pair of Arrays that are weakly congruent and typekind conform with the srcArray, dstArray pair. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the sizes of the undistributed dimensions, that vary faster with memory than the first distributed dimension, are permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

srcArray ESMF_Array with source data.

dstArray ESMF_Array with destination data. The data in this Array may be destroyed by this call.

routehandle Handle to the precomputed Route.

[srcToDstTransposeMap] List with as many entries as there are dimensions in srcArray. Each entry maps the corresponding srcArray dimension against the specified dstArray dimension. Mixing of distributed and undistributed dimensions is supported.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstanding during a redist exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

The ESMF_ArraySMMStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument >= 0 is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified.
on return. If the provided argument is < 0, the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.30 ESMF_ArrayScatter - Scatter a Fortran array across the ESMF_Array

INTERFACE:

subroutine ESMF_ArrayScatter(array, farray, rootPet, tile, vm, rc)

ARGUMENTS:

type(ESMF_Array), intent(inout) :: array
<type> (ESMF_KIND_<kind>), intent(in), target :: farray(<rank>)
integer, intent(in) :: rootPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: tile
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Scatter the data of farray located on rootPET across an ESMF_Array object. A single farray must be scattered across a single DistGrid tile in Array. The optional tile argument allows selection of the tile. For Arrays defined on a single tile DistGrid the default selection (tile 1) will be correct. The shape of farray must match the shape of the tile in Array.

If the Array contains replicating DistGrid dimensions data will be scattered across all of the replicated pieces.

This version of the interface implements the PET-based blocking paradigm: Each PET of the VM must issue this call exactly once for all of its DEs. The call will block until all PET-local data objects are accessible.

The arguments are:

array The ESMF_Array object across which data will be scattered.

{farray} The Fortran array that is to be scattered. Only root must provide a valid farray, the other PETs may treat farray as an optional argument.

rootPet PET that holds the valid data in farray.

{tile} The DistGrid tile in array into which to scatter farray. By default farray will be scattered into tile 1.
Optional ESMF_VM object of the current context. Providing the VM of the current context will lower the method’s overhead.

Return code; equals ESMF_SUCCESS if there are no errors.

27.5.31 ESMF_ArraySet - Set object-wide Array information

INTERFACE:

! Private name; call using ESMF_ArraySet()
subroutine ESMF_ArraySetDefault(array, computationalLWidth, &
               computationalUWidth, name, rc)

ARGUMENTS:

   type(ESMF_Array), intent(inout) :: array
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer, intent(in), optional :: computationalLWidth(:, :)
   integer, intent(in), optional :: computationalUWidth(:, :)
   character(len = *), intent(in), optional :: name
   integer, intent(out), optional :: rc

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets adjustable settings in an ESMF_Array object. Arrays with tensor dimensions will set values for all tensor components.

The arguments are:

array ESMF_Array object for which to set properties.

[name] The Array name.

[computationalLWidth] This argument must have of size (dimCount, localDeCount).
   computationalLWidth specifies the lower corner of the computational region with respect to the lower corner of the exclusive region for all local DEs.

[computationalUWidth] This argument must have of size (dimCount, localDeCount).
   computationalUWidth specifies the upper corner of the computational region with respect to the upper corner of the exclusive region for all local DEs.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
27.5.32  ESMF_ArraySet - Set DE-local Array information

INTERFACE:

! Private name; call using ESMF_ArraySet()
subroutine ESMF_ArraySetPLocalDe(array, localDe, rimSeqIndex, rc)

ARGUMENTS:

type(ESMF_Array),  intent(inout)  :: array
integer,           intent(in)    :: localDe
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer,           intent(in), optional :: rimSeqIndex(:)
integer,           intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets adjustable settings in an ESMF_Array object for a specific localDe.
The arguments are:

array  ESMF_Array object for which to set properties.
localDe Local DE for which to set values.

[rimSeqIndex]  Sequence indices in the halo rim of localDe.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.33  ESMF_ArraySMM - Execute an Array sparse matrix multiplication

INTERFACE:

subroutine ESMF_ArraySMM(srcArray, dstArray, routehandle, &
routesyncflag, finishedflag, cancelledflag, zeroregion, termorderflag, &
checkflag, rc)

ARGUMENTS:

type(ESMF_Array),  intent(in), optional :: srcArray
type(ESMF_Array),  intent(inout), optional :: dstArray
type(ESMF_RouteHandle), intent(inout)  :: routehandle
The following arguments require argument keyword syntax (e.g. rc=rc). --

`; type(ESMF_RouteSync_Flag), intent(in), optional :: routesyncflag
`; logical, intent(out), optional :: finishedflag
`; logical, intent(out), optional :: cancelledflag
`; type(ESMF_Region_Flag), intent(in), optional :: zeroregion
`; type(ESMF_TermOrder_Flag), intent(in), optional :: termorderflag
`; logical, intent(out), optional :: checkflag
`; integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

- **6.1.0** Added argument `termorderflag`. The new argument gives the user control over the order in which the src terms are summed up.

DESCRIPTION:

Execute a precomputed Array sparse matrix multiplication from `srcArray` to `dstArray`. Both `srcArray` and `dstArray` must be weakly congruent and typekind conform to the respective Arrays used during `ESMF_ArraySMMStore()`.

Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the size of the undistributed dimensions, that vary faster with memory than the first distributed dimension, is permitted to be different. This means that the same `routehandle` can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

The `srcArray` and `dstArray` arguments are optional in support of the situation where `srcArray` and/or `dstArray` are not defined on all PETs. The `srcArray` and `dstArray` must be specified on those PETs that hold source or destination DEs, respectively, but may be omitted on all other PETs. PETs that hold neither source nor destination DEs may omit both arguments.

It is erroneous to specify the identical Array object for `srcArray` and `dstArray` arguments.

See `ESMF_ArraySMMStore()` on how to precompute `routehandle`. See section 27.2.17 for details on the operation `ESMF_ArraySMM()` performs.

This call is collective across the current VM.

[srcArray] ESMF_Array with source data.

[dstArray] ESMF_Array with destination data.

[routehandle] Handle to the precomputed Route.

[routesyncflag] Indicate communication option. Default is `ESMF_ROUTESYNC_BLOCKING`, resulting in a blocking operation. See section 50.44 for a complete list of valid settings.

[finishedflag] Used in combination with `routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH`. Returned `finishedflag` equal to `.true.` indicates that all operations have finished. A value
of .false. indicates that there are still unfinished operations that require additional calls with routesyncflag = ESMF_ROUTESYNC_NBTESTFINISH, or a final call with routesyncflag = ESMF_ROUTESYNC_NBWAITFINISH. For all other routesyncflag settings the returned value in finishedflag is always .true..

[cancelledflag] A value of .true. indicates that were cancelled communication operations. In this case the data in the dstArray must be considered invalid. It may have been partially modified by the call. A value of .false. indicates that none of the communication operations was cancelled. The data in dstArray is valid if finishedflag returns equal .true..

[zeroregion] If set to ESMF_REGION_TOTAL (default) the total regions of all DEs in dstArray will be initialized to zero before updating the elements with the results of the sparse matrix multiplication. If set to ESMF_REGION_EMPTY the elements in dstArray will not be modified prior to the sparse matrix multiplication and results will be added to the incoming element values. Setting zeroregion to ESMF_REGION_SELECT will only zero out those elements in the destination Array that will be updated by the sparse matrix multiplication. See section 50.43 for a complete list of valid settings.

[termorderflag] Specifies the order of the source side terms in all of the destination sums. The termorderflag only affects the order of terms during the execution of the RouteHandle. See the 35.2.1 section for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods. See for a full list of options. The default is ESMF_TERMORDER_FREE, allowing maximum flexibility in the order of terms for optimum performance.

[checkflag] If set to .TRUE. the input Array pair will be checked for consistency with the precomputed operation provided by routehandle. If set to .FALSE. (default) only a very basic input check will be performed, leaving many inconsistencies undetected. Set checkflag to .FALSE. to achieve highest performance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

27.5.34 ESMF_ArraySMMRelease - Release resources associated with Array sparse matrix multiplication

INTERFACE:

```fortran
subroutine ESMF_ArraySMMRelease(routehandle, rc)
```

ARGUMENTS:

```fortran
type(ESMF_RouteHandle), intent(inout) :: routehandle
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Release resources associated with an Array sparse matrix multiplication. After this call routehandle becomes invalid.
routehandle  Handle to the precomputed Route.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

27.5.35  ESMF_ArraySMMStore - Precompute Array sparse matrix multiplication with local factors

INTERFACE:

! Private name; call using ESMF_ArraySMMStore()
subroutine ESMF_ArraySMMStore<type><kind>(srcArray, dstArray, &
  routehandle, factorList, factorIndexList, &
  srcTermProcessing, pipelineDepth, rc)

ARGUMENTS:

type(ESMF_Array), intent(in) :: srcArray

type(ESMF_Array), intent(inout) :: dstArray

type(ESMF_RouteHandle), intent(inout) :: routehandle

<type>(ESMF_KIND_<kind>), target, intent(in) :: factorList(:)

integer, intent(in) :: factorIndexList(:,:)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(inout), optional :: srcTermProcessing

integer, intent(inout), optional :: pipelineDepth

integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0  Added argument srcTermProcessing. Added argument pipelineDepth. The new arguments provide access to the tuning parameters affecting the sparse matrix execution.

DESCRIPTION:

ESMF_ArraySMMStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_ArraySMMStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_ArraySMMStore() method, as provided through the separate entry points shown in 27.5.35 and 27.5.36, is described in the following paragraphs as a whole.

Store an Array sparse matrix multiplication operation from srcArray to dstArray. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with
size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

Both srcArray and dstArray are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section [27.2.17] for details on the definition of sequence indices.

Source and destination Arrays, as well as the supplied factorList argument, may be of different <type><kind>. Further source and destination Arrays may differ in shape and number of elements.

It is erroneous to specify the identical Array object for srcArray and dstArray arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArraySMM() on any pair of Arrays that are weakly congruent and typekind conform with the srcArray, dstArray pair. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the size of the undistributed dimensions, that vary faster with memory than the first distributed dimension, is permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This method is overloaded for:
ESMF_TYPEKIND_I4, ESMF_TYPEKIND_I8,
ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

This call is collective across the current VM.

srcArray ESMF_Array with source data.
dstArray ESMF_Array with destination data. The data in this Array may be destroyed by this call.
routehandle Handle to the precomputed Route.
factorList List of non-zero coefficients.
factorIndexList Pairs of sequence indices for the factors stored in factorList.

The second dimension of factorIndexList steps through the list of pairs, i.e. size(factorIndexList,2) == size(factorList). The first dimension of factorIndexList is either of size 2 or size 4.

In the size 2 format factorIndexList(1,:) specifies the sequence index of the source element in the srcArray while factorIndexList(2,:) specifies the sequence index of the destination element in dstArray. For this format to be a valid option source and destination Arrays must have matching number of tensor elements (the product of the sizes of all Array tensor dimensions). Under this condition an identity matrix can be applied within the space of tensor elements for each sparse matrix factor.

The size 4 format is more general and does not require a matching tensor element count. Here the factorIndexList(1,:) specifies the sequence index while factorIndexList(2,:) specifies the tensor sequence index of the source element in the srcArray. Further factorIndexList(3,:) specifies the sequence index and factorIndexList(4,:) specifies the tensor sequence index of the destination element in the dstArray.

See section [27.2.17] for details on the definition of Array sequence indices and tensor sequence indices.

[srcTermProcessing] The srcTermProcessing parameter controls how many source terms, located on the same PET and summing into the same destination element, are summed into partial sums on the source PET before being transferred to the destination PET. A value of 0 indicates that the entire arithmetic is done on the destination PET; source elements are neither multiplied by their factors nor added into partial sums before being sent off by the source PET. A value of 1 indicates that source elements are multiplied by their factors on the source side before being sent to the destination PET. Larger values of srcTermProcessing indicate the maximum number of terms in the partial sums on the source side.
Note that partial sums may lead to bit-for-bit differences in the results. See section 35.2.1 for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods.

The ESMF_ArraySMMStore() method implements an auto-tuning scheme for the srcTermProcessing parameter. The intent on the srcTermProcessing argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the srcTermProcessing parameter, and the auto-tuning phase is skipped. In this case the srcTermProcessing argument is not modified on return. If the provided argument is \( < 0 \), the srcTermProcessing parameter is determined internally using the auto-tuning scheme. In this case the srcTermProcessing argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional srcTermProcessing argument is omitted.

[pipelineDepth] The pipelineDepth parameter controls how many messages a PET may have outstanding during a sparse matrix exchange. Larger values of pipelineDepth typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors.

Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

The ESMF_ArraySMMStore() method implements an auto-tuning scheme for the pipelineDepth parameter. The intent on the pipelineDepth argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the pipelineDepth parameter, and the auto-tuning phase is skipped. In this case the pipelineDepth argument is not modified on return. If the provided argument is \( < 0 \), the pipelineDepth parameter is determined internally using the auto-tuning scheme. In this case the pipelineDepth argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional pipelineDepth argument is omitted.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

27.5.36 ESMF_ArraySMMStore - Precompute Array sparse matrix multiplication without local factors

INTERFACE:

! Private name; call using ESMF_ArraySMMStore()
subroutine ESMF_ArraySMMStoreNF(srcArray, dstArray, routehandle, &
    srcTermProcessing, pipelineDepth, rc)

ARGUMENTS:

    type(ESMF_Array), intent(in) :: srcArray
    type(ESMF_Array), intent(inout) :: dstArray
    type(ESMF_RouteHandle), intent(inout) :: routehandle

    -- The following arguments require argument keyword syntax (e.g. rc=rc).
    integer, intent(inout), optional :: srcTermProcessing
    integer, intent(inout), optional :: pipelineDepth
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
This interface was modified since ESMF version 5.2.0r. Changes made after the 5.2.0r release:

6.1.0 Added argument srcTermProcessing. Added argument pipelineDepth. The new arguments provide access to the tuning parameters affecting the sparse matrix execution.

DESCRIPTION:

ESMF_ArraySMMStore() is a collective method across all PETs of the current Component. The interface of the method is overloaded, allowing – in principle – each PET to call into ESMF_ArraySMMStore() through a different entry point. Restrictions apply as to which combinations are sensible. All other combinations result in ESMF run time errors. The complete semantics of the ESMF_ArraySMMStore() method, as provided through the separate entry points shown in 27.5.35 and 27.5.36, is described in the following paragraphs as a whole.

Store an Array sparse matrix multiplication operation from srcArray to dstArray. PETs that specify non-zero matrix coefficients must use the <type><kind> overloaded interface and provide the factorList and factorIndexList arguments. Providing factorList and factorIndexList arguments with size(factorList) = (/0/) and size(factorIndexList) = (/2,0/) or (/4,0/) indicates that a PET does not provide matrix elements. Alternatively, PETs that do not provide matrix elements may also call into the overloaded interface without factorList and factorIndexList arguments.

Both srcArray and dstArray are interpreted as sequentialized vectors. The sequence is defined by the order of DistGrid dimensions and the order of tiles within the DistGrid or by user-supplied arbitrary sequence indices. See section 27.2.17 for details on the definition of sequence indices.

Source and destination Arrays, as well as the supplied factorList argument, may be of different <type><kind>. Further source and destination Arrays may differ in shape and number of elements.

It is erroneous to specify the identical Array object for srcArray and dstArray arguments.

The routine returns an ESMF_RouteHandle that can be used to call ESMF_ArraySMM() on any pair of Arrays that are weakly congruent and typekind conform with the srcArray, dstArray pair. Congruent Arrays possess matching DistGrids, and the shape of the local array tiles matches between the Arrays for every DE. For weakly congruent Arrays the size of the undistributed dimensions, that vary faster with memory than the first distributed dimension, is permitted to be different. This means that the same routehandle can be applied to a large class of similar Arrays that differ in the number of elements in the left most undistributed dimensions.

This call is collective across the current VM.

srcArray ESMF_Array with source data.

dstArray ESMF_Array with destination data. The data in this Array may be destroyed by this call.

routehandle Handle to the precomputed Route.

[srcTermProcessing] The srcTermProcessing parameter controls how many source terms, located on the same PET and summing into the same destination element, are summed into partial sums on the source PET before being transferred to the destination PET. A value of 0 indicates that the entire arithmetic is done on the destination PET; source elements are neither multiplied by their factors nor added into partial sums before being sent off by the source PET. A value of 1 indicates that source elements are multiplied by their factors on the source side before being sent to the destination PET. Larger values of srcTermProcessing indicate the maximum number of terms in the partial sums on the source side.

Note that partial sums may lead to bit-for-bit differences in the results. See section 35.2.1 for an in-depth discussion of all bit-for-bit reproducibility aspects related to route-based communication methods.
The `ESMF_ArraySMMStore()` method implements an auto-tuning scheme for the `srcTermProcessing` parameter. The intent on the `srcTermProcessing` argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the `srcTermProcessing` parameter, and the auto-tuning phase is skipped. In this case the `srcTermProcessing` argument is not modified on return. If the provided argument is \( < 0 \), the `srcTermProcessing` parameter is determined internally using the auto-tuning scheme. In this case the `srcTermProcessing` argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional `srcTermProcessing` argument is omitted.

The `pipelineDepth` parameter controls how many messages a PET may have outstanding during a sparse matrix exchange. Larger values of `pipelineDepth` typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors. Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

The `ESMF_ArraySMMStore()` method implements an auto-tuning scheme for the `pipelineDepth` parameter. The intent on the `pipelineDepth` argument is "inout" in order to support both overriding and accessing the auto-tuning parameter. If an argument \( \geq 0 \) is specified, it is used for the `pipelineDepth` parameter, and the auto-tuning phase is skipped. In this case the `pipelineDepth` argument is not modified on return. If the provided argument is \( < 0 \), the `pipelineDepth` parameter is determined internally using the auto-tuning scheme. In this case the `pipelineDepth` argument is re-set to the internally determined value on return. Auto-tuning is also used if the optional `pipelineDepth` argument is omitted.

**[pipelineDepth]** The `pipelineDepth` parameter controls how many messages a PET may have outstanding during a sparse matrix exchange. Larger values of `pipelineDepth` typically lead to better performance. However, on some systems too large a value may lead to performance degradation, or runtime errors. Note that the pipeline depth has no affect on the bit-for-bit reproducibility of the results. However, it may affect the performance reproducibility of the exchange.

27.5.37 ESMF.ArrayValidate - Validate object-wide Array information

**INTERFACE:**

```latex
subroutine ESMF_ArrayValidate(array, rc)
```

**ARGUMENTS:**

- `type(ESMF_Array), intent(in) :: array`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Validates that the `Array` is internally consistent. The method returns an error code if problems are found.

The arguments are:

- `array` Specified `ESMF_Array` object.
- `rc` Return code; equals `ESMF_SUCCESS` if there are no errors.
27.5.38  ESMF_ArrayWrite - Write Array data into a file

INTERFACE:

    subroutine ESMF_ArrayWrite(array, file, &
        variableName, overwrite, status, timeslice, iofmt, rc)

ARGUMENTS:

    type(ESMF_Array), intent(in) :: array
    character(*), intent(in) :: file
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(*), intent(in), optional :: variableName
    logical, intent(in), optional :: overwrite
    type(ESMF_FileStatus_Flag), intent(in), optional :: status
    integer, intent(in), optional :: timeslice
    type(ESMF_IOFmt_Flag), intent(in), optional :: iofmt
    integer, intent(out), optional :: rc

DESCRIPTION:

Write Array data into a file. For this API to be functional, the environment variable ESMFPIO should be set to "internal" when the ESMF library is built. Please see the section on Data I/O, 36.3.

Limitations:

- Only 1 DE per PET supported.
- Not supported in ESMF_COMM=mpiuni mode.

The arguments are:

array  The ESMF_Array object that contains data to be written.

file  The name of the output file to which Array data is written.

[variableName] Variable name in the output file; default is the "name" of Array. Use this argument only in the IO format (such as NetCDF) that supports variable name. If the IO format does not support this (such as binary format), ESMF will return an error code.

[overwrite] A logical flag, the default is .false., i.e., existing field data may not be overwritten. If .true., the overwrite behavior depends on the value of iofmt as shown below:

    iofmt = ESMF_IOFMT_BIN: All data in the file will be overwritten with each field’s data.
    iofmt = ESMF_IOFMT_NETCDF: Only the data corresponding to each field’s name will be overwritten. If the timeslice option is given, only data for the given timeslice may be overwritten. Note that it is always an error to attempt to overwrite a NetCDF variable with data which has a different shape.

[status] The file status. Please see Section 50.19 for the list of options. If not present, defaults to ESMF_FILESTATUS_UNKNOWN.

[timeslice] Some IO formats (e.g. NetCDF) support the output of data in form of time slices. The timeslice argument provides access to this capability. timeslice must be positive. The behavior of this option may depend on the setting of the overwrite flag:
overwrite = .false.: If the timeslice value is less than the maximum time already in the file, the write will fail.
overwrite = .true.: Any positive timeslice value is valid.

By default, i.e. by omitting the timeslice argument, no provisions for time slicing are made in the output file, however, if the file already contains a time axis for the variable, a timeslice one greater than the maximum will be written.

[iofmt] The IO format. Please see Section 50.26 for the list of options. If not present, defaults to ESMF_IOFMT_NETCDF.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

28 LocalArray Class

28.1 Description

The ESMF_LocalArray class provides a language independent representation of data in array format. One of the major functions of the LocalArray class is to bridge the Fortran/C/C++ language difference that exists with respect to array representation. All ESMF Field and Array data is internally stored in ESMF LocalArray objects allowing transparent access from Fortran and C/C++.

In the ESMF Fortran API the LocalArray becomes visible in those cases where a local PET may be associated with multiple pieces of an Array, e.g. if there are multiple DEs associated with a single PET. The Fortran language standard does not provide an array of arrays construct, however arrays of derived types holding arrays are possible. ESMF calls use arguments that are of type ESMF_LocalArray with dimension attributes where necessary.

28.2 Restrictions and Future Work

- The TKR (type/kind/rank) overloaded LocalArray interfaces declare the dummy Fortran array arguments with the pointer attribute. The advantage of doing this is that it allows ESMF to inquire information about the provided Fortran array. The disadvantage of this choice is that actual Fortran arrays passed into these interfaces must also be defined with pointer attribute in the user code.

28.3 Class API

28.3.1 ESMF_LocalArrayAssignment(=) - LocalArray assignment

INTERFACE:

```fortran
interface assignment(=)
  localarray1 = localarray2
end interface
```

ARGUMENTS:

- type(ESMF_LocalArray) :: localarray1
- type(ESMF_LocalArray) :: localarray2
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign localarray1 as an alias to the same ESMF LocalArray object in memory as localarray2. If localarray2 is invalid, then localarray1 will be equally invalid after the assignment.

The arguments are:

- **localarray1** The ESMF_LocalArray object on the left hand side of the assignment.
- **localarray2** The ESMF_LocalArray object on the right hand side of the assignment.

### 28.3.2 ESMF_LocalArrayOperator(==) - LocalArray equality operator

**INTERFACE:**

```plaintext
interface operator(==)
  if (localarray1 == localarray2) then ... endif
or
  result = (localarray1 == localarray2)
end interface operator(==)
```

**RETURN VALUE:**

- logical :: result

**ARGUMENTS:**

- type(ESMF_LocalArray), intent(in) :: localarray1
- type(ESMF_LocalArray), intent(in) :: localarray2

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Test whether localarray1 and localarray2 are valid aliases to the same ESMF LocalArray object in memory. For a more general comparison of two ESMF LocalArrays, going beyond the simple alias test, the ESMF_LocalArrayMatch() function (not yet implemented) must be used.

The arguments are:

- **localarray1** The ESMF_LocalArray object on the left hand side of the equality operation.
- **localarray2** The ESMF_LocalArray object on the right hand side of the equality operation.
28.3.3 ESMF_LocalArrayOperator(=/=) - LocalArray not equal operator

INTERFACE:

    interface operator(/=)
    if (localarray1 /= localarray2) then ... endif
    OR
    result = (localarray1 /= localarray2)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_LocalArray), intent(in) :: localarray1
    type(ESMF_LocalArray), intent(in) :: localarray2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether localarray1 and localarray2 are not valid aliases to the same ESMF LocalArray object in memory. For a more general comparison of two ESMF LocalArrays, going beyond the simple alias test, the ESMF_LocalArrayMatch() function (not yet implemented) must be used.

The arguments are:

localarray1 The ESMF_LocalArray object on the left hand side of the non-equality operation.
localarray2 The ESMF_LocalArray object on the right hand side of the non-equality operation.

28.3.4 ESMF_LocalArrayCreate – Create a LocalArray by explicitly specifying typekind and rank arguments

INTERFACE:

    ! Private name; call using ESMF_LocalArrayCreate()
    function ESMF_LocalArrayCreateByTKR(typekind, rank, totalcount, &
        totalLBound, totalUBound, rc)

RETURN VALUE:

    type(ESMF_LocalArray) :: ESMF_LocalArrayCreateByTKR
ARGUMENTS:

- `type(ESMF_TypeKind_Flag), intent(in) :: typekind`
- `integer, intent(in) :: rank`
- `integer, intent(in), optional :: totalCount(:)`
- `integer, intent(in), optional :: totalLBound(:)`
- `integer, intent(in), optional :: totalUBound(:)`
- `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create a new `ESMF_LocalArray` and allocate data space, which remains uninitialized. The return value is a new `LocalArray`.

The arguments are:

- **typekind** Array typekind. See section 50.52 for valid values.
- **rank** Array rank (dimensionality, 1D, 2D, etc). Maximum allowed is 7D.
- **totalCount** The number of items in each dimension of the array. This is a 1D integer array the same length as the rank. The `count` argument may be omitted if both `totalLBound` and `totalUBound` arguments are present.
- **totalLBound** An integer array of length rank, with the lower index for each dimension.
- **totalUBound** An integer array of length rank, with the upper index for each dimension.
- **rc** Return code; equals ESMF_SUCCESS if there are no errors.

28.3.5 ESMF_LocalArrayCreate – Create a LocalArray by specifying an ArraySpec

INTERFACE:

```fortran
! Private name; call using ESMF_LocalArrayCreate()
function ESMF_LocalArrayCreateBySpec(arrayspec, totalCount, &
  totalLBound, totalUBound, rc)
```

RETURN VALUE:

- `type(ESMF_LocalArray) :: ESMF_LocalArrayCreateBySpec`
type (ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: totalCount(:)
  integer, intent(in), optional :: totalLBound(:)
  integer, intent(in), optional :: totalUBound(:)
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create a new ESMF_LocalArray and allocate data space, which remains uninitialized. The return value is a new LocalArray.

The arguments are:

arrayspec  ArraySpec object specifying typekind and rank.
[totalCount] The number of items in each dimension of the array. This is a 1D integer array the same length as the rank. The count argument may be omitted if both totalLBound and totalUBound arguments are present.
[totalLBound] An integer array of length rank, with the lower index for each dimension.
[totalUBound] An integer array of length rank, with the upper index for each dimension.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

28.3.6 ESMF_LocalArrayCreate – Create a LocalArray from pre-existing LocalArray

INTERFACE:

! Private name; call using ESMF_LocalArrayCreate()
function ESMF_LocalArrayCreateCopy(localarray, rc)

RETURN VALUE:

type (ESMF_LocalArray) :: ESMF_LocalArrayCreateCopy

ARGUMENTS:

  type (ESMF_LocalArray), intent(in) :: localarray
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Perform a deep copy of an existing ESMF_LocalArray object. The return value is a new LocalArray.

The arguments are:

localarray Existing LocalArray to be copied.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

28.3.7 ESMF_LocalArrayCreate - Create a LocalArray from a Fortran pointer (associated or unassociated)

INTERFACE:

! Private name; call using ESMF_LocalArrayCreate()
function ESMF_LocalArrCreateByPtr<rank><type><kind>(farrayPtr, &
datacopyflag, totalCount, totalLBound, totalUBound, rc)

RETURN VALUE:

type(ESMF_LocalArray) :: ESMF_LocalArrCreateByPtr<rank><type><kind>

ARGUMENTS:

<type> (ESMF_KIND_<kind>), pointer :: farrayPtr<rank>)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(in), optional :: totalCount(:)
integer, intent(in), optional :: totalLBound(:)
integer, intent(in), optional :: totalUBound(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Creates an ESMF_LocalArray based on a Fortran array pointer. Two cases must be distinguished.

First, if farrayPtr is associated the optional datacopyflag argument may be used to indicate whether the associated data is to be copied or referenced. For associated farrayPtr the optional totalCount, totalLBound
and totalUBound arguments need not be specified. However, all present arguments will be checked against farrayPtr for consistency.

Second, if farrayPtr is unassociated the optional argument datacopyflag must not be specified. However, in this case a complete set of totalCount and bounds information must be provided. Any combination of present totalCount totalLBound and totalUBound arguments that provides a complete specification is valid. All input information will be checked for consistency.

The arguments are:

- **farrayPtr**  A Fortran array pointer (associated or unassociated).
- **[datacopyflag]** Indicate copy vs. reference behavior in case of associated farrayPtr. This argument must not be present for unassociated farrayPtr. Default to ESMF_DATA_COPY_REFERENCE, makes the ESMF_LocalArray reference the associated data array. If set to ESMF_DATA_COPY_VALUE this routine allocates new memory and copies the data from the pointer into the new LocalArray allocation.
- **[totalCount]** The number of items in each dimension of the array. This is a 1D integer array the same length as the rank. The count argument may be omitted if both totalLBound and totalUBound arguments are present.
- **[totalLBound]** An integer array of lower index values. Must be the same length as the rank.
- **[totalUBound]** An integer array of upper index values. Must be the same length as the rank.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 28.3.8 ESMF_LocalArrayDestroy - Release resources associated with a LocalArray

**INTERFACE:**

```fortran
subroutine ESMF_LocalArrayDestroy(localarray, rc)
```

**ARGUMENTS:**

- `type(ESMF_LocalArray), intent(inout) :: localarray`
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  - `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Destroys an ESMF_LocalArray, releasing all resources associated with the object.

The arguments are:

- **localarray**  Destroy contents of this ESMF_LocalArray.
- **[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.
28.3.9 ESMF_LocalArrayGet - Get object-wide LocalArray information

INTERFACE:

! Private name; call using ESMF_LocalArrayGet()
subroutine ESMF_LocalArrayGetDefault(localarray, &
   typekind, rank, totalCount, totalLBound, totalUBound, rc)

ARGUMENTS:

   type(ESMF_LocalArray), intent(in) :: localarray
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_TypeKind_Flag), intent(out), optional :: typekind
   integer, intent(out), optional :: rank
   integer, intent(out), optional :: totalCount(:)
   integer, intent(out), optional :: totalLBound(:)
   integer, intent(out), optional :: totalUBound(:)
   integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns information about the ESMF_LocalArray.

The arguments are:

- localarray Queried ESMF_LocalArray object.
- [typekind] TypeKind of the LocalArray object.
- [rank] Rank of the LocalArray object.
- [totalCount] Count per dimension.
- [totalLBound] Lower bound per dimension.
- [totalUBound] Upper bound per dimension.
- [rc] Return code; equals ESMF_SUCCESS if there are no errors.

28.3.10 ESMF_LocalArrayGet - Get a Fortran array pointer from a LocalArray

INTERFACE:
subroutine ESMF_LocalArrayGetData<rank><type><kind>(localarray, farrayPtr, & datacopyflag, rc)

ARGUMENTS:

  type(ESMF_LocalArray) :: localarray
  <type> (ESMF_KIND_<kind>), pointer :: farrayPtr
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Return a Fortran pointer to the data buffer, or return a Fortran pointer to a new copy of the data.

The arguments are:

localarray  The ESMF_LocalArray to get the value from.

farrayPtr  An unassociated or associated Fortran pointer correctly allocated.

[datacopyflag]  An optional copy flag which can be specified. Can either make a new copy of the data or reference existing data. See section 50.12 for a list of possible values.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

29 ArraySpec Class

29.1 Description

An ArraySpec is a very simple class that contains type, kind, and rank information about an Array. This information is stored in two parameters. TypeKind describes the data type of the elements in the Array and their precision. Rank is the number of dimensions in the Array.

The only methods that are associated with the ArraySpec class are those that allow you to set and retrieve this information.

29.2 Use and Examples

The ArraySpec is passed in as an argument at Field and FieldBundle creation in order to describe an Array that will be allocated or attached at a later time. There are any number of situations in which this approach is useful. One
common example is a case in which the user wants to create a very flexible export State with many diagnostic variables predefined, but only a subset desired and consequently allocated for a particular run.

```
! !PROGRAM: ESMF_ArraySpecEx - ArraySpec manipulation examples
!
! !DESCRIPTION:
!
! This program shows examples of ArraySpec set and get usage
!-----------------------------------------------------------------------------
#include "ESMF.h"

    ! ESMF Framework module
    use ESMF
    use ESMF_TestMod
    implicit none

    ! local variables
    type(ESMF_ArraySpec) :: arrayDS
    integer :: myrank
    type(ESMF_TypeKind_Flag) :: mytypekind

    ! return code
    integer:: rc, result
    character(ESMF_MAXSTR) :: testname
    character(ESMF_MAXSTR) :: failMsg

    ! initialize ESMF framework
    call ESMF_Initialize(defaultlogfilename="ArraySpecEx.Log", &
                        logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
```

### 29.2.1 Set ArraySpec values

This example shows how to set values in an ESMF_ArraySpec.

```
call ESMF_ArraySpecSet(arrayDS, rank=2, &
typekind=ESMF_TYPEKIND_R8, rc=rc)
```

### 29.2.2 Get ArraySpec values

This example shows how to query an ESMF_ArraySpec.

```
call ESMF_ArraySpecGet(arrayDS, rank=.rank, &
typekind=mytypekind, rc=rc)
print *, "Returned values from ArraySpec:")
print *, "rank =", myrank

! finalize ESMF framework
call ESMF_Finalize(rc=rc)

end program ESMF_ArraySpecEx

29.3 Restrictions and Future Work

1. Limit on rank. The values for type, kind and rank passed into the ArraySpec class are subject to the same limitations as Arrays. The maximum array rank is 7, which is the highest rank supported by Fortran.

29.4 Design and Implementation Notes

The information contained in an ESMF_ArraySpec is used to create ESMF_Array objects. ESMF_ArraySpec is a shallow class, and only set and get methods are needed. They do not need to be created or destroyed.

29.5 Class API

29.5.1 ESMF_ArraySpecAssignment(=) - Assign an ArraySpec to another ArraySpec

INTERFACE:

interface assignment(=)
  arrayspec1 = arrayspec2
end interface

ARGUMENTS:

  type(ESMF_ArraySpec) :: arrayspec1
  type(ESMF_ArraySpec) :: arrayspec2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Set arrayspec1 equal to arrayspec2. This is the default Fortran assignment, which creates a complete, independent copy of arrayspec2 as arrayspec1. If arrayspec2 is an invalid ESMF_ArraySpec object then arrayspec1 will be equally invalid after the assignment.

The arguments are:
arrayspec1 The ESMF_ArraySpec to be set.
arrayspec2 The ESMF_ArraySpec to be copied.

29.5.2 ESMF_ArraySpecOperator(==) - Test if ArraySpec 1 is equal to ArraySpec 2

INTERFACE:

interface operator(==)
  if (arrayspec1 == arrayspec2) then ... endif
  OR
  result = (arrayspec1 == arrayspec2)
end interface

RETURN VALUE:

logical :: result

ARGUMENTS:

type(ESMF_ArraySpec), intent(in) :: arrayspec1
type(ESMF_ArraySpec), intent(in) :: arrayspec2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (==) operator for the ESMF_ArraySpec class to return .true. if arrayspec1 and arrayspec2 specify the same type, kind and rank, and .false. otherwise.

The arguments are:

arrayspec1 First ESMF_ArraySpec in comparison.
arrayspec2 Second ESMF_ArraySpec in comparison.

29.5.3 ESMF_ArraySpecOperator(/=) - Test if ArraySpec 1 is not equal to ArraySpec 2

INTERFACE:

interface operator(/=)
  if (arrayspec1 /= arrayspec2) then ... endif
  OR
  result = (arrayspec1 /= arrayspec2)
end interface

550
RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_ArraySpec), intent(in) :: arrayspec1
    type(ESMF_ArraySpec), intent(in) :: arrayspec2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (=/=) operator for the ESMF_ArraySpec class to return .true. if arrayspec1 and arrayspec2 do not specify the same type, kind or rank, and .false. otherwise.

The arguments are:

arrayspec1  First ESMF_ArraySpec in comparison.
arrayspec2  Second ESMF_ArraySpec in comparison.

29.5.4  ESMF_ArraySpecGet - Get values from an ArraySpec

INTERFACE:

    subroutine ESMF_ArraySpecGet(arrayspec, rank, typekind, rc)

ARGUMENTS:

    type(ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rank
    type(ESMF_TypeKind_Flag), intent(out), optional :: typekind
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns information about the contents of an ESMF_ArraySpec.

The arguments are:
arrayspec  The ESMF_ArraySpec to query.
[rank]  Array rank (dimensionality – 1D, 2D, etc). Maximum possible is 7D.
[typekind]  Array typekind. See section 50.52 for valid values.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

29.5.5  ESMF_ArraySpecPrint - Print ArraySpec information

INTERFACE:

    subroutine ESMF_ArraySpecPrint(arrayspec, rc)

ARGUMENTS:

    type(ESMF_ArraySpec), intent(in) :: arrayspec
    -- The following arguments require argument keyword syntax (e.g. rc=rc).
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Print ArraySpec internals.

The arguments are:

arrayspec  Specified ESMF_ArraySpec object.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

29.5.6  ESMF_ArraySpecSet - Set values for an ArraySpec

INTERFACE:

    subroutine ESMF_ArraySpecSet(arrayspec, rank, typekind, rc)

ARGUMENTS:
type(ESMF_ArraySpec), intent(out) :: arrayspec
integer, intent(in) :: rank

type(ESMF_TypeKind_Flag), intent(in) :: typekind

-- The following arguments require argument keyword syntax (e.g. rc=rc).
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Creates a description of the data – the typekind, the rank, and the dimensionality.

The arguments are:

arrayspec  The ESMF_ArraySpec to set.
rank  Array rank (dimensionality – 1D, 2D, etc). Maximum allowed is 7D.
typekind  Array typekind. See section 50.52 for valid values.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

29.5.7  ESMF_ArraySpecValidate - Validate ArraySpec internals

INTERFACE:

subroutine ESMF_ArraySpecValidate(arrayspec, rc)

ARGUMENTS:

type(ESMF_ArraySpec), intent(in) :: arrayspec
-- The following arguments require argument keyword syntax (e.g. rc=rc).
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Validates that the arrayspec is internally consistent. The method returns an error code if problems are found.

The arguments are:

arrayspec  Specified ESMF_ArraySpec object.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
30 Grid Class

30.1 Description

The ESMF Grid class is used to describe the geometry and discretization of logically rectangular physical grids. It also contains the description of the grid’s underlying topology and the decomposition of the physical grid across the available computational resources. The most frequent use of the Grid class is to describe physical grids in user code so that sufficient information is available to perform ESMF methods such as regridding.

Key Features

- Representation of grids formed by logically rectangular regions, including uniform and rectilinear grids (e.g. lat-lon grids), curvilinear grids (e.g. displaced pole grids), and grids formed by connected logically rectangular regions (e.g. cubed sphere grids).
- Support for 1D, 2D, 3D, and higher dimension grids.
- Distribution of grids across computational resources for parallel operations - users set which grid dimensions are distributed.
- Grids can be created already distributed, so that no single resource needs global information during the creation process.
- Options to define periodicity and other edge connectivities either explicitly or implicitly via shape shortcuts.
- Options for users to define grid coordinates themselves or call prefabricated coordinate generation routines for standard grids [NO GENERATION ROUTINES YET].
- Options for incremental construction of grids.
- Options for using a set of pre-defined stagger locations or for setting custom stagger locations.

30.1.1 Grid Representation in ESMF

ESMF Grids are based on the concepts described in *A Standard Description of Grids Used in Earth System Models* [Balaji 2006]. In this document Balaji introduces the mosaic concept as a means of describing a wide variety of Earth system model grids. A mosaic is composed of grid tiles connected at their edges. Mosaic grids includes simple, single tile grids as a special case.

The ESMF Grid class is a representation of a mosaic grid. Each ESMF Grid is constructed of one or more logically rectangular Tiles. A Tile will usually have some physical significance (e.g. the region of the world covered by one face of a cubed sphere grid).

The piece of a Tile that resides on one DE (for simple cases, a DE can be thought of as a processor - see section on the DELayout) is called a LocalTile. For example, the six faces of a cubed sphere grid are each Tiles, and each Tile can be divided into many LocalTiles.

Every ESMF Grid contains a DistGrid object, which defines the Grid’s index space, topology, distribution, and connectivities. It enables the user to define the complex edge relationships of tripole and other grids. The DistGrid can be created explicitly and passed into a Grid creation routine, or it can be created implicitly if the user takes a Grid creation shortcut. The DistGrid used in Grid creation describes the properties of the Grid cells. In addition to this one, the Grid internally creates DistGrids for each stagger location. These stagger DistGrids are related to the original DistGrid, but may contain extra padding to represent the extent of the index space of the stagger. These DistGrids are what are used when a Field is created on a Grid.
30.1.2 Supported Grids

The range of supported grids in ESMF can be defined by:

- Types of topologies and shapes supported. ESMF supports one or more logically rectangular grid Tiles with connectivities specified between cells. For more details see section 30.1.3.
- Types of distributions supported. ESMF supports regular, irregular, or arbitrary distributions of data. For more details see section 30.1.4.
- Types of coordinates supported. ESMF supports uniform, rectilinear, and curvilinear coordinates. For more details see section 30.1.5.

30.1.3 Grid Topologies and Periodicity

ESMF has shortcuts for the creation of standard Grid topologies or shapes up to 3D. In many cases, these enable the user to bypass the step of creating a DistGrid before creating the Grid. There are two sets of methods which allow the user to do this. These two sets of methods cover the same set of topologies, but allow the user to specify them in different ways.

The first set of these are a group of overloaded calls broken up by the number of periodic dimensions they specify. With these the user can pick the method which creates a Grid with the number of periodic dimensions they need, and then specify other connectivity options via arguments to the method. The following is a description of these methods:

ESMF_GridCreateNoPeriDim() Allows the user to create a Grid with no edge connections, for example, a regional Grid with closed boundaries.

ESMF_GridCreate1PeriDim() Allows the user to create a Grid with 1 periodic dimension and supports a range of options for what to do at the pole (see Section 30.2.5). Some examples of Grids which can be created here are tripole spheres, bipole spheres, cylinders with open poles.

ESMF_GridCreate2PeriDim() Allows the user to create a Grid with 2 periodic dimensions, for example a torus, or a regional Grid with doubly periodic boundaries.

More detailed information can be found in the API description of each.

The second set of shortcut methods is a set of methods overloaded under the name ESMF_GridCreate(). These methods allow the user to specify the connectivities at the end of each dimension, by using the ESMF_GridConn_Flag flag. The table below shows the ESMF_GridConn_Flag settings used to create standard shapes in 2D using the ESMF_GridCreate() call. Two values are specified for each dimension, one for the low end and one for the high end of the dimension's index values.

<table>
<thead>
<tr>
<th>2D Shape</th>
<th>connflagDim1(1)</th>
<th>connflagDim1(2)</th>
<th>connflagDim2(1)</th>
<th>connflagDim2(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rectangle</td>
<td>NONE</td>
<td>NONE</td>
<td>NONE</td>
<td>NONE</td>
</tr>
<tr>
<td>Bipole Sphere</td>
<td>POLE</td>
<td>POLE</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
</tr>
<tr>
<td>Tripole Sphere</td>
<td>POLE</td>
<td>BIPOLE</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
</tr>
<tr>
<td>Cylinder</td>
<td>NONE</td>
<td>NONE</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
</tr>
<tr>
<td>Torus</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
<td>PERIODIC</td>
</tr>
</tbody>
</table>

If the user’s grid shape is too complex for an ESMF shortcut routine, or involves more than three dimensions, a DistGrid can be created to specify the shape in detail. This DistGrid is then passed into a Grid create call.
30.1.4 Grid Distribution

ESMF Grids have several options for data distribution (also referred to as decomposition). As ESMF Grids are cell based, these options are all specified in terms of how the cells in the Grid are broken up between DEs.

The main distribution options are regular, irregular, and arbitrary. A regular distribution is one in which the same number of contiguous grid cells are assigned to each DE in the distributed dimension. An irregular distribution is one in which unequal numbers of contiguous grid cells are assigned to each DE in the distributed dimension. An arbitrary distribution is one in which any grid cell can be assigned to any DE. Any of these distribution options can be applied to any of the grid shapes (i.e., rectangle) or types (i.e., rectilinear). Support for arbitrary distribution is limited in the current version of ESMF, see Section 30.3.7 for an example of creating a Grid with an arbitrary distribution.

Figure 13 illustrates options for distribution.

A distribution can also be specified using the DistGrid, by passing object into a Grid create call.

30.1.5 Grid Coordinates

Grid Tiles can have uniform, rectilinear, or curvilinear coordinates. The coordinates of uniform grids are equally spaced along their axes, and can be fully specified by the coordinates of the two opposing points that define the grid’s physical span. The coordinates of rectilinear grids are unequally spaced along their axes, and can be fully specified by giving the spacing of grid points along each axis. The coordinates of curvilinear grids must be specified by giving the explicit set of coordinates for each grid point. Curvilinear grids are often uniform or rectilinear grids that have been warped; for example, to place a pole over a land mass so that it does not affect the computations performed on an ocean model grid. Figure 14 shows examples of each type of grid.

Each of these coordinate types can be set for each of the standard grid shapes described in section 30.1.3.

The table below shows how examples of common single Tile grids fall into this shape and coordinate taxonomy. Note that any of the grids in the table can have a regular or arbitrary distribution.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Uniform</th>
<th>Rectilinear</th>
<th>Curvilinear</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sphere</td>
<td>Global uniform lat-lon grid</td>
<td>Gaussian grid</td>
<td>Displaced pole grid</td>
</tr>
<tr>
<td>Rectangle</td>
<td>Regional uniform lat-lon grid</td>
<td>Gaussian grid section</td>
<td>Polar stereographic grid section</td>
</tr>
</tbody>
</table>
There are two ways of specifying coordinates in ESMF. The first way is for the user to set the coordinates. The second way is to take a shortcut and have the framework generate the coordinates.

No ESMF generation routines are currently available. See Section 30.3.10 for more description and examples of setting coordinates.

30.1.7 Staggering

Staggering is a finite difference technique in which the values of different physical quantities are placed at different locations within a grid cell.

The ESMF Grid class supports a variety of stagger locations, including cell centers, corners, and edge centers. The default stagger location in ESMF is the cell center, and cell counts in Grid are based on this assumption. Combinations of the 2D ESMF stagger locations are sufficient to specify any of the Arakawa staggers. ESMF also supports staggering in 3D and higher dimensions. There are shortcuts for standard staggers, and interfaces through which users can create custom staggers.

As a default the ESMF Grid class provides symmetric staggering, so that cell centers are enclosed by cell perimeter (e.g. corner) stagger locations. This means the coordinate arrays for stagger locations other than the center will have an additional element of padding in order to enclose the cell center locations. However, to achieve other types of staggering, the user may alter or eliminate this padding by using the appropriate options when adding coordinates to a Grid.

In the current release, only the cell center stagger location is supported for an arbitrarily distributed grid. For examples and a full description of the stagger interface see Section 30.3.10.

30.1.8 Masking

Masking is the process whereby parts of a grid can be marked to be ignored during an operation, such as regridding. Masking can be used on a source grid to indicate that certain portions of the grid should not be used to generate regridded data. This is useful, for example, if a portion of the source grid contains unusable values. Masking can also be used on a destination grid to indicate that the portion of the field built on that part of the Grid should not receive
regridded data. This is useful, for example, when part of the grid isn’t being used (e.g. the land portion of an ocean grid).

ESMF regrid currently supports masking for Fields built on structured Grids and element masking for Fields built on unstructured Meshes. The user may mask out points in the source Field or destination Field or both. To do masking the user sets mask information in the Grid (see 30.3.14) or Mesh (see 32.3.8) upon which the Fields passed into the ESMF_FieldRegridStore() call are built. The srcMaskValues and dstMaskValues arguments to that call can then be used to specify which values in that mask information indicate that a location should be masked out. For example, if dstMaskValues is set to (/1,2/), then any location that has a value of 1 or 2 in the mask information of the Grid or Mesh upon which the destination Field is built will be masked out.

Masking behavior differs slightly between regridding methods. For non-conservative regridding methods (e.g. bilinear or high-order patch), masking is done on points. For these methods, masking a destination point means that that point won’t participate in regridding (e.g. won’t be interpolated to). For these methods, masking a source point means that the entire source cell using that point is masked out. In other words, if any corner point making up a source cell is masked then the cell is masked. For conservative regridding methods (e.g. first-order conservative) masking is done on cells. Masking a destination cell means that the cell won’t participate in regridding (e.g. won’t be interpolated to). Similarly, masking a source cell means that the cell won’t participate in regridding (e.g. won’t be interpolated from). For any type of interpolation method (conservative or non-conservative) the masking is set on the location upon which the Fields passed into the regridding call are built. For example, if Fields built on ESMF_STAGGERLOC_CENTER are passed into the ESMF_FieldRegridStore() call then the masking should also be set on ESMF_STAGGERLOC_CENTER.

30.2 Constants

30.2.1 ESMF_GRIDCONN

DESCRIPTION:

The ESMF_GridCreateShapeTile command has three specific arguments connflagDim1, connflagDim2, and connflagDim3. These can be used to setup different types of connections at the ends of each dimension of a Tile. Each of these parameters is a two element array. The first element is the connection type at the minimum end of the dimension and the second is the connection type at the maximum end. The default value for all the connections is ESMF_GRIDCONN_NONE, specifying no connection.

The type of this flag is:

type(ESMF_GridConn_Flag)

The valid values are:

ESMF_GRIDCONN_NONE No connection.

ESMF_GRIDCONN_PERIODIC Periodic connection.

ESMF_GRIDCONN_POLE This edge is connected to itself. Given that the edge is n elements long, then element i is connected to element i+n/2.

ESMF_GRIDCONN_BIPOLE This edge is connected to itself. Given that the edge is n elements long, element i is connected to element n-i-1.
30.2.2 ESMF_GRIDITEM

DESCRIPTION:
The ESMF Grid can contain other kinds of data besides coordinates. This data is referred to as Grid “items”. Some items may be used by ESMF for calculations involving the Grid. The following are the valid values of ESMF_GridItem_Flag.

The type of this flag is:

\[ \text{type}(\text{ESMF\_GridItem\_Flag}) \]

The valid values are:

<table>
<thead>
<tr>
<th>Item Label</th>
<th>Type Restriction</th>
<th>Type Default</th>
<th>ESMF Uses</th>
<th>Controls</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESMF_GRIDITEM_MASK</td>
<td>ESMF_TYPEKIND_I4</td>
<td>ESMF_TYPEKIND_I4</td>
<td>YES</td>
<td>Masking in Regrid</td>
</tr>
<tr>
<td>ESMF_GRIDITEM_AREA</td>
<td>NONE</td>
<td>ESMF_TYPEKIND_R8</td>
<td>YES</td>
<td>Conservation in Regrid</td>
</tr>
</tbody>
</table>

30.2.3 ESMF_GRIDMATCH

DESCRIPTION:
This type is used to indicate the level to which two grids match.

The type of this flag is:

\[ \text{type}(\text{ESMF\_GridMatch\_Flag}) \]

The valid values are:

- **ESMF\_GRIDMATCH\_INVALID**: Indicates a non-valid matching level. Returned if an error occurs in the matching function. If a higher matching level is returned then no error occurred.
- **ESMF\_GRIDMATCH\_NONE**: The lowest level of grid matching. This indicates that the Grid’s don’t match at any of the higher levels.
- **ESMF\_GRIDMATCH\_EXACT**: All the pieces of the Grid (e.g. distgrids, coordinates, etc.) except the name, match between the two Grids.
- **ESMF\_GRIDMATCH\_ALIAS**: Both Grid variables are aliases to the exact same Grid object in memory.

30.2.4 ESMF_GRIDSTATUS

DESCRIPTION:
The ESMF Grid class can exist in two states. These states are present so that the library code can detect if a Grid has been appropriately setup for the task at hand. The following are the valid values of ESMF\_GRIDSTATUS.

The type of this flag is:

\[ \text{type}(\text{ESMF\_GridStatus\_Flag}) \]

The valid values are:

- **ESMF\_GRIDSTATUS\_EMPTY**: Status after a Grid has been created with `ESMF\_GridEmptyCreate`. A Grid object container is allocated but space for internal objects is not. Topology information and coordinate information is incomplete. This object can be used in `ESMF\_GridEmptyComplete()` methods in which additional information is added to the Grid.
**ESMF_GRIDSTATUS_COMPLETE**: The Grid has a specific topology and distribution, but incomplete coordinate arrays. The Grid can be used as the basis for allocating a Field, and coordinates can be added via `ESMF_GridCoordAdd()` to allow other functionality.

### 30.2.5 ESMF_POLEKIND

**DESCRIPTION:**
This type describes the type of connection that occurs at the pole when a Grid is created with `ESMF_GridCreate1PeriodicDim()`.

The type of this flag is:

```python
type(ESMF_PoleKind_Flag)
```

The valid values are:

- **ESMF_POLEKIND_NONE**  No connection at pole.
- **ESMF_POLEKIND_MONOPOLE**  This edge is connected to itself. Given that the edge is n elements long, then element i is connected to element i+n/2.
- **ESMF_POLEKIND_BIPOLE**  This edge is connected to itself. Given that the edge is n elements long, element i is connected to element n-i-1.

### 30.2.6 ESMF_STAGGERLOC

**DESCRIPTION:**
In the ESMF Grid class, data can be located at different positions in a Grid cell. When setting or retrieving coordinate data the stagger location is specified to tell the Grid method from where in the cell to get the data. Although the user may define their own custom stagger locations, ESMF provides a set of predefined locations for ease of use. The following are the valid predefined stagger locations.

The 2D predefined stagger locations (illustrated in figure 15) are:

- **ESMF_STAGGERLOC_CENTER**: The center of the cell.
- **ESMF_STAGGERLOC_CORNER**: The corners of the cell.
- **ESMF_STAGGERLOC_EDGE1**: The edges offset from the center in the 1st dimension.
- **ESMF_STAGGERLOC_EDGE2**: The edges offset from the center in the 2nd dimension.

The 3D predefined stagger locations (illustrated in figure 16) are:

- **ESMF_STAGGERLOC_CENTER_VCENTER**: The center of the 3D cell.
Figure 15: 2D Predefined Stagger Locations

Figure 16: 3D Predefined Stagger Locations
ESMF_STAGGERLOC_CORNER_VCENTER: Half way up the vertical edges of the cell.

ESMF_STAGGERLOC_EDGE1_VCENTER: The center of the face bounded by edge 1 and the vertical dimension.

ESMF_STAGGERLOC_EDGE2_VCENTER: The center of the face bounded by edge 2 and the vertical dimension.

ESMF_STAGGERLOC_CORNER_VFACE: The corners of the 3D cell.

ESMF_STAGGERLOC_EDGE1_VFACE: The center of the edges of the 3D cell parallel offset from the center in the 1st dimension.

ESMF_STAGGERLOC_EDGE2_VFACE: The center of the edges of the 3D cell parallel offset from the center in the 2nd dimension.

ESMF_STAGGERLOC_CENTER_VFACE: The center of the top and bottom face. The face bounded by the 1st and 2nd dimensions.

30.2.7 ESMF_FILEFORMAT

DESCRIPTION:
This option is used by ESMF_GridCreate to specify the type of the input grid file. See sections 12.4 and 12.6 for more detailed description of the supported file formats.

The type of this flag is:

\texttt{type(ESMF_FileFormat\_Flag)}

The valid values are:

\texttt{ESMF\_FILEFORMAT\_SCRIP} SCRIP format grid file. The SCRIP format is the format accepted by the SCRIP regridding tool [16]. For Grid creation, files of this type only work when the \texttt{grid\_rank} in the file is equal to 2.

\texttt{ESMF\_FILEFORMAT\_GRIDSPEC} a single tile grid file confroming with the proposed CF-GRIDSPEC conventions.

30.3 Use and Examples

This section describes the use of the ESMF Grid class. It first discusses the more user friendly shape specific interface to the Grid. During this discussion it covers creation and options, adding stagger locations, coordinate data access, and other grid functionality. After this initial phase the document discusses the more advanced options which the user can employ should they need more customized interaction with the Grid class.

30.3.1 Create single-tile Grid shortcut method

The set of methods \texttt{ESMF\_GridCreateNoPeriDim()}, \texttt{ESMF\_GridCreate1PeriDim()}, \texttt{ESMF\_GridCreate2PeriDim()}, and \texttt{ESMF\_GridCreate()} are shortcuts for building 2D or 3D single tile logically rectangular Grids. These methods support all three types of distributions described in Section 30.1.4 regular, irregular and arbitrary.
The ESMF Grid is cell based and so for all distribution options the methods take as input the number of cells to describe the total index space and the number of cells to specify distribution.

To create a Grid with a regular distribution the user specifies the global maximum and minimum ranges of the Grid cell index space (maxIndex and minIndex), and the number of pieces in which to partition each dimension (via a regDecomp argument). ESMF then divides the index space as evenly as possible into the specified number of pieces. If there are cells left over then they are distributed one per DE starting from the first DE until they are gone.

If minIndex is not specified, then the bottom of the Grid cell index range is assumed to be (1,1,...,1). If regDecomp is not specified, then by default ESMF creates a distribution that partitions the grid cells in the first dimension (e.g. NPx1x1...1) as evenly as possible by the number of processors NP. The remaining dimensions are not partitioned. The dimension of the Grid is the size of maxIndex. The following is an example of creating a 10x20x30 3D grid where the first dimensions is broken into 2 pieces, the second is broken into 4 pieces, and the third is "distributed" across only one processor.

\[
\text{grid3D=ESMF\_GridCreateNoPeriDim(regDecomp=(/2,4,1/), maxIndex=(/10,20,30/), } \& \\
\text{rc=rc)}
\]

Irregular distribution requires the user to specify the exact number of Grid cells per DE in each dimension. In the ESMF_GridCreateNoPeriDim() call the countsPerDEDim1, countsPerDEDim2, and countsPerDEDim3 arguments are used to specify a rectangular distribution containing size(countsPerDEDim1) by size(countsPerDEDim2) by size(countsPerDEDim3) DEs. The entries in each of these arrays specify the number of grid cells per DE in that dimension. The dimension of the grid is determined by the presence of countsPerDEDim3. If it's present the Grid will be 3D. If just countsPerDEDim1 and countsPerDEDim2 are specified the Grid will be 2D.

The following call illustrates the creation of a 10x20 two dimensional rectangular Grid distributed across six DEs that are arranged 2x3. In the first dimension there are 3 grid cells on the first DE and 7 cells on the second DE. The second dimension has 3 DEs with 11, 2, and 7 cells, respectively.

\[
\text{grid2D=ESMF\_GridCreateNoPeriDim(countsPerDEDim1=(/3,7/), } \& \\
\text{countsPerDEDim2=(/11,2,7/), rc=rc)}
\]

To add a distributed third dimension of size 30, broken up into two groups of 15, the above call would be altered as follows.

\[
\text{grid3d=ESMF\_GridCreateNoPeriDim(countsPerDEDim1=(/3,7/), } \& \\
\text{countsPerDEDim2=(/11,2,7/), countsPerDEDim3=(/15,15/), rc=rc)}
\]

To make a third dimension distributed across only 1 DE, then countsPerDEDim3 in the call should only have a single term.

\[
\text{grid3D=ESMF\_GridCreateNoPeriDim(countsPerDEDim1=(/3,7/), } \& \\
\text{countsPerDEDim2=(/11,2,7/), countsPerDEDim3=(/30/), rc=rc)}
\]

The petMap parameter may be used to specify on to which specific PETs the DEs in the Grid are assigned. Note that this parameter is only available for the regular and irregular distribution types. The petMap array is a 3D array, for a 3D Grid each of its dimensions correspond to a Grid dimension. If the Grid is 2D, then the
first two dimensions correspond to Grid dimensions and the last dimension should be of size 1. The size of each 
petMap dimension is the number of DE’s along that dimension in the Grid. For a regular Grid, the size is equal 
to the number in regDecomp (i.e. size(petMap,d)=regDecomp(d) for all dimensions d in the Grid). For 
an irregular Grid the size is equal to the number of items in the corresponding countsPerDEDim variable (i.e. 
size(petMap,d)=size(countsPerDEDimd) for all dimensions d in the Grid).

The petMap parameter may be used to specify on to which specific PETs Each entry in petMap specifies to which 
PET the corresponding DE should be assigned. For example, petMap(3,2)=4 tells the Grid create call to put the 
DE located at column 3 row 2 on PET 4.

The petMap parameter may be used to specify on to which specific PETs The following example demonstrates how 
to specify the PET to DE association for an ESMF_GridCreateNoPeriDim() call.

```fortran
! allocate memory for petMap
allocate( petMap(2,2,1) )
!
! Set petMap
petMap(:,1,1) = (/3,2/) ! DE (1,1,1) on PET 3 and DE (2,1,1) on PET 2
petMap(:,2,1) = (/1,0/) ! DE (1,2,1) on PET 1 and DE (2,2,1) on PET 0
!
! Let the 3D grid be be distributed only in the first two dimensions.
grid2D=ESMF_GridCreateNoPeriDim(countsPerDEDim1=(/3,7/), &
     countsPerDEDim2=(/7,6/), petMap=petMap, rc=rc)
```

To create an grid with arbitrary distribution, the user specifies the global minimum and maximum ranges of the index 
space with the arguments minIndex and maxIndex, the total number of cells and their index space locations resid-
ing on the local PET through a localArbIndexCount and a localArbIndex argument. localArbIndex is a 
2D array with size (localArbIndexCount, n) where n is the total number dimensions distributed arbitrarily. 
Again, if minIndex is not specified, then the bottom of the index range is assumed to be (1,1,...). The dimension 
of the Grid is equal to the size of maxIndex. If n (number of arbitrarily distributed dimension) is less than the grid 
dimension, an optional argument distDim is used to specify which of the grid dimension is arbitrarily distributed. If 
not given, the first n dimensions are assumed to be distributed.

The following example creates a 2D Grid of dimensions 5x5, and places the diagonal elements (i.e. indices (i,i) 
where i goes from 1 to 5) on the local PET. The remaining PETs would individually declare the remainder of the Grid 
locations.

```fortran
! allocate memory for localArbIndex
allocate( localArbIndex(5,2) )
!
! Set local indices
localArbIndex(1,:)=(/1,1/)
localArbIndex(2,:)=(/2,2/)
localArbIndex(3,:)=(/3,3/)
localArbIndex(4,:)=(/4,4/)
localArbIndex(5,:)=(/5,5/)
!
! Create a 2D Arbitrarily distributed Grid
grid2D=ESMF_GridCreateNoPeriDim(maxIndex=(/5,5/), &
     arbIndexList=localArbIndex, arbIndexCount=5, rc=rc)
```

To create a 3D Grid of dimensions 5x6x5 with the first and the third dimensions distributed arbitrarily, distDim is 
used.
! Create a 3D Grid with the 1st and 3rd dimension arbitrarily distributed
grid3D=ESMF_GridCreateNoPeriDim(maxIndex=(/5,6,5/), &
    arbIndexList=localArbIndex, arbIndexCount=5, &
    distDim=(/1,3/), rc=rc)

30.3.2 Create a 2D regularly distributed rectilinear Grid with uniformly spaced coordinates

The following is an example of creating a simple rectilinear grid and loading in a set of coordinates. It illustrates a straightforward use of the ESMF_GridCreateNoPeriDim() call described in the previous section. This code creates a 10x20 2D grid with uniformly spaced coordinates varying from (10,10) to (100,200). The grid is partitioned using a regular distribution. The first dimension is divided into two pieces, and the second dimension is divided into 3. This example assumes that the code is being run with a 1-1 mapping between PETs and DEs because we are only accessing the first DE on each PET (localDE=0). Because we have 6 DEs (2x3), this example would only work when run on 6 PETs. The Grid is created with global indices. After Grid creation the local bounds and native Fortran arrays are retrieved and the coordinates are set by the user.

!-------------------------------------------------- -----------------
! Create the Grid: Allocate space for the Grid object, define the
! topology and distribution of the Grid, and specify that it
! will have global indices. Note that here aperiodic bounds are
! specified by the argument name. In this call the minIndex hasn’t
! been set, so it defaults to (1,1,...). The default is to
! divide the index range as equally as possible among the DEs
! specified in regDecomp. This behavior can be changed by
! specifying decompFlag.
!-------------------------------------------------- -----------------
grid2D=ESMF_GridCreateNoPeriDim( &
    ! Define a regular distribution
    maxIndex=(/10,20/), & ! define index space
    regDecomp=(/2,3/), & ! define how to divide among DEs
    coordSys=ESMF_COORDSYS_CART, & ! Specify mapping of coords dim to Grid dim
    coordDep1=(/1/), & ! 1st coord is 1D and depends on 1st Grid dim
    coordDep2=(/2/), & ! 2nd coord is 1D and depends on 2nd Grid dim
    indexflag=ESMF_INDEX_GLOBAL, &
    rc=rc)

!-------------------------------------------------- -----------------
! Allocate coordinate storage and associate it with the center
! stagger location. Since no coordinate values are specified in
! this call no coordinate values are set yet.
!-------------------------------------------------- -----------------
call ESMF_GridAddCoord(grid2D, &
    staggerloc=ESMF_STAGGERLOC_CENTER, rc=rc)

!-------------------------------------------------- -----------------
! Get the pointer to the first coordinate array and the bounds
.Data
! of its global indices on the local DE.
!-------------------------------------------------------------
call ESMF_GridGetCoord(grid2D, coordDim=1, localDE=0, &
   staggerloc=ESMF_STAGGERLOC_CENTER, &
   computationalLBound=lbnd, computationalUBound=ubnd, &
   farrayPtr=coordX, rc=rc)
!-------------------------------------------------------------
! Calculate and set coordinates in the first dimension [10-100].
!-------------------------------------------------------------
do i=lbnd(1),ubnd(1)
   coordX(i) = i*10.0
enddo
!-------------------------------------------------------------
! Get the pointer to the second coordinate array and the bounds of
! its global indices on the local DE.
!-------------------------------------------------------------
call ESMF_GridGetCoord(grid2D, coordDim=2, localDE=0, &
   staggerloc=ESMF_STAGGERLOC_CENTER, &
   computationalLBound=lbnd, computationalUBound=ubnd, &
   farrayPtr=coordY, rc=rc)
!-------------------------------------------------------------
! Calculate and set coordinates in the second dimension [10-200]
!-------------------------------------------------------------
do j=lbnd(1),ubnd(1)
   coordY(j) = j*10.0
enddo

30.3.3 Create a periodic 2D regularly distributed rectilinear Grid

The following is an example of creating a simple rectilinear grid with a periodic dimension and loading in a set of coordinates. It illustrates a straightforward use of the ESMF_GridCreate1PeriDim() call described in the previous section. This code creates a 10x20 2D grid with uniformly spaced coordinates varying from (1,1) to (360,180). The grid is partitioned using a regular distribution. The first dimension is divided into two pieces, and the second dimension is divided into 3. This example assumes that the code is being run with a 1-1 mapping between PETs and DEs because we are only accessing the first DE on each PET (localDE=0). Because we have 6 DEs (2x3), this example would only work when run on 6 PETs. The Grid is created with global indices. After Grid creation the local bounds and native Fortran arrays are retrieved and the coordinates are set by the user.

!-------------------------------------------------------------
! Create the Grid: Allocate space for the Grid object, define the
! topology and distribution of the Grid, and specify that it
! will have global indices. Note that here a single periodic connection
! is specified by the argument name. In this call the minIndex hasn’t
! been set, so it defaults to (1,1,...). The default is to

566
! divide the index range as equally as possible among the DEs
! specified in regDecomp. This behavior can be changed by
! specifying decompFlag. Since the coordinate system is
! not specified, it defaults to ESMF_COORDSYS_SPH_DEG.
-------------------------------------------------------------------
grid2D=ESMF_GridCreate1PeriDim(
 &
 ! Define a regular distribution
 maxIndex=(/360,180/), & ! define index space
 regDecomp=(/2,3/), & ! define how to divide among DEs
 ! Specify mapping of coords dim to Grid dim
 coordDep1=(/1/), & ! 1st coord is 1D and depends on 1st Grid dim
 coordDep2=(/2/), & ! 2nd coord is 1D and depends on 2nd Grid dim
 indexflag=ESMF_INDEX_GLOBAL, &
 rc=rc)
-------------------------------------------------------------------
! Allocate coordinate storage and associate it with the center
! stagger location. Since no coordinate values are specified in
! this call no coordinate values are set yet.
-------------------------------------------------------------------
call ESMF_GridAddCoord(grid2D, &
 staggerloc=ESMF_STAGGERLOC_CENTER, rc=rc)
-------------------------------------------------------------------
! Get the pointer to the first coordinate array and the bounds
! of its global indices on the local DE.
-------------------------------------------------------------------
call ESMF_GridGetCoord(grid2D, coordDim=1, localDE=0, &
 staggerloc=ESMF_STAGGERLOC_CENTER, &
 computationalLBound=lbnd, computationalUBound=ubnd, &
 farrayPtr=coordX, rc=rc)
-------------------------------------------------------------------
! Calculate and set coordinates in the first dimension [10-100].
-------------------------------------------------------------------
do i=lbnd(1),ubnd(1)
    coordX(i) = i*1.0
enddo
-------------------------------------------------------------------
! Get the pointer to the second coordinate array and the bounds of
! its global indices on the local DE.
-------------------------------------------------------------------
call ESMF_GridGetCoord(grid2D, coordDim=2, localDE=0, &
 staggerloc=ESMF_STAGGERLOC_CENTER, &
The remaining examples in this section will use the irregular distribution because of its greater generality. To create code similar to these, but using a regular distribution, replace the countsPerDEDim arguments in the Grid create with the appropriate maxIndex and regDecomp arguments.

30.3.4 Create a 2D irregularly distributed rectilinear Grid with uniformly spaced coordinates

This example serves as an illustration of the difference between using a regular and irregular distribution. It repeats the previous example except using an irregular distribution to give the user more control over how the cells are divided between the DEs. As before, this code creates a 10x20 2D Grid with uniformly spaced coordinates varying from (10,10) to (100,200). In this example, the Grid is partitioned using an irregular distribution. The first dimension is divided into two pieces, the first with 3 Grid cells per DE and the second with 7 Grid cells per DE. In the second dimension, the Grid is divided into 3 pieces, with 11, 2, and 7 cells per DE respectively. This example assumes that the code is being run with a 1-1 mapping between PETs and DEs because we are only accessing the first DE on each PET (localDE=0). Because we have 6 DEs (2x3), this example would only work when run on 6 PETs. The Grid is created with global indices. After Grid creation the local bounds and native Fortran arrays are retrieved and the coordinates are set by the user.
! stagger location. Since no coordinate values are specified in
! this call no coordinate values are set yet.
!-------------------------------------------------- -----------------
call ESMF_GridAddCoord(grid2D, &
  staggerloc=ESMF_STAGGERLOC_CENTER, rc=rc)
!-------------------------------------------------- -----------------

! Get the pointer to the first coordinate array and the bounds
! of its global indices on the local DE.
!-------------------------------------------------- -----------------
call ESMF_GridGetCoord(grid2D, coordDim=1, localDE=0, &
  staggerloc=ESMF_STAGGERLOC_CENTER, &
  computationalLBound=lbnd, computationalUBound=ubnd, &
  farrayPtr=coordX, rc=rc)
!-------------------------------------------------- -----------------

! Calculate and set coordinates in the first dimension [10-100].
!-------------------------------------------------- -----------------
do i=lbnd(1),ubnd(1)
  coordX(i) = i*10.0
enddo

!-------------------------------------------------- -----------------

! Get the pointer to the second coordinate array and the bounds of
! its global indices on the local DE.
!-------------------------------------------------- -----------------
call ESMF_GridGetCoord(grid2D, coordDim=2, localDE=0, &
  staggerloc=ESMF_STAGGERLOC_CENTER, &
  computationalLBound=lbnd, computationalUBound=ubnd, &
  farrayPtr=coordY, rc=rc)
!-------------------------------------------------- -----------------

! Calculate and set coordinates in the second dimension [10-200]
!-------------------------------------------------- -----------------
do j=lbnd(1),ubnd(1)
  coordY(j) = j*10.0
enddo

30.3.5 Create a 2D irregularly distributed Grid with curvilinear coordinates

The following is an example of creating a simple curvilinear Grid and loading in a set of coordinates. It creates a 10x20
2D Grid where the coordinates vary along every dimension. The Grid is partitioned using an irregular distribution. The
first dimension is divided into two pieces, the first with 3 Grid cells per DE and the second with 7 Grid cells per DE.
In the second dimension, the Grid is divided into 3 pieces, with 11, 2, and 7 cells per DE respectively. This example
assumes that the code is being run with a 1-1 mapping between PETs and DEs because we are only accessing the first
DE on each PET (localDE=0). Because we have 6 DEs (2x3), this example would only work when run on 6 PETs. The Grid is created with global indices. After Grid creation the local bounds and native Fortran arrays are retrieved and the coordinates are set by the user.

!-------------------------------------------------- -----------------
! Create the Grid: Allocate space for the Grid object, define the 
! distribution of the Grid, and specify that it 
! will have global indices. Note that aperiodic bounds are 
! indicated by the method name. If periodic bounds were desired they 
! could be specified by using the ESMF_GridCreate1PeriDim() call. 
! In this call the minIndex hasn’t been set, so it defaults to (1,1,...). 
!-------------------------------------------------- -----------------
grid2D=ESMF_GridCreateNoPeriDim( &
  ! Define an irregular distribution
  countsPerDEDim1=(/3,7/), &
  countsPerDEDim2=(/11,2,7/), &
  ! Specify mapping of coords dim to Grid dim
  coordDep1=(/1,2/), & ! 1st coord is 2D and depends on both Grid dim
  coordDep2=(/1,2/), & ! 2nd coord is 1D and depends on both Grid dim
  indexflag=ESMF_INDEX_GLOBAL, &
  rc=rc)

!-------------------------------------------------- -----------------
! Allocate coordinate storage and associate it with the center 
! stagger location. Since no coordinate values are specified in 
! this call no coordinate values are set yet. 
!-------------------------------------------------- -----------------
call ESMF_GridAddCoord(grid2D, &
  staggerloc=ESMF_STAGGERLOC_CENTER, rc=rc)

!-------------------------------------------------- -----------------
! Get the pointer to the first coordinate array and the bounds 
! of its global indices on the local DE. 
!-------------------------------------------------- -----------------
call ESMF_GridGetCoord(grid2D, coordDim=1, localDE=0, &
  staggerloc=ESMF_STAGGERLOC_CENTER, &
  computationalLBound=lbnd, computationalUBound=ubnd, &
  farrayPtr=coordX2D, rc=rc)

!-------------------------------------------------- -----------------
! Calculate and set coordinates in the first dimension [10-100]. 
!-------------------------------------------------- -----------------
do j=lbnd(2),ubnd(2)
do i=lbnd(1),ubnd(1)
  coordX2D(i,j) = i+j

570
30.3.6 Create an irregularly distributed rectilinear Grid with a non-distributed vertical dimension

This example demonstrates how a user can build a rectilinear horizontal Grid with a non-distributed vertical dimension. The Grid contains both the center and corner stagger locations (i.e. Arakawa B-Grid). In contrast to the previous examples, this example doesn’t assume that the code is being run with a 1-1 mapping between PETs and DEs. It should work when run on any number of PETs.

grid3D=ESMF_GridCreateNoPeriDim( &}
  ! Define an irregular distribution
  countsPerDEDim1=(/45,75,40,20/), &
  countsPerDEDim2=(/30,40,20/), &
  countsPerDEDim3=(/40/), &
  ! Specify mapping of coords dim to Grid dim
  coordDep1=(/1/), & ! 1st coord is 1D and depends on 1st Grid dim
  coordDep2=(/2/), & ! 2nd coord is 1D and depends on 2nd Grid dim
  coordDep3=(/3/), & ! 3rd coord is 1D and depends on 3rd Grid dim
  indexflag=ESMF_INDEX_GLOBAL, & ! Use global indices
  rc=rc)
! Allocate coordinate storage for both center and corner stagger
! locations. Since no coordinate values are specified in this
! call no coordinate values are set yet.
!
call ESMF_GridAddCoord(grid3D, &
   staggerloc=ESMF_STAGGERLOC_CENTER_VCENTER, rc=rc)

call ESMF_GridAddCoord(grid3D, &
   staggerloc=ESMF_STAGGERLOC_CORNER_VCENTER, rc=rc)
!
call ESMF_GridGet(grid3D, localDECount=localDECount, rc=rc)

! Loop over each localDE when accessing data
!
do lDE=0,localDECount-1

! Fill in the coordinates for the corner stagger location first.
!
call ESMF_GridGetCoord(grid3D, coordDim=1, localDE=lDE, &
   staggerLoc=ESMF_STAGGERLOC_CORNER_VCENTER, &
   computationalLBound=lbnd_corner, &
   computationalUBound=ubnd_corner, &
   farrayPtr=cornerX, rc=rc)
!-------------------------------------------------- --------------
! Calculate and set coordinates in the first dimension.
!-------------------------------------------------- --------------
do i=lbnd_corner(1),ubnd_corner(1)
   cornerX(i) = (i-1)*(360.0/180.0)
enddo

!-------------------------------------------------- --------------
! Get the local bounds of the global indexing for the second
! coordinate array on the local DE. Also get the pointer to the
! second coordinate array.
!-------------------------------------------------- --------------
call ESMF_GridGetCoord(grid3D, coordDim=2, localDE=lDE, &
   staggerLoc=ESMF_STAGGERLOC_CORNER_VCENTER, &
   computationalLBound=lbnd_corner, &
   computationalUBound=ubnd_corner, &
   farrayPtr=cornerY, rc=rc)

!-------------------------------------------------- --------------
! Calculate and set coordinates in the second dimension.
!-------------------------------------------------- --------------
do j=lbnd_corner(1),ubnd_corner(1)
   cornerY(j) = (j-1)*(180.0/90.0)
enddo

!-------------------------------------------------- --------------
! Get the local bounds of the global indexing for the third
! coordinate array on the local DE, and the pointer to the array.
!-------------------------------------------------- --------------
call ESMF_GridGetCoord(grid3D, coordDim=3, localDE=lDE, &
   staggerLoc=ESMF_STAGGERLOC_CENTER_VCENTER, &
   computationalLBound=lbnd, computationalUBound=ubnd, &
   farrayPtr=cornerZ, rc=rc)

!-------------------------------------------------- --------------
! Calculate and set the vertical coordinates
!-------------------------------------------------- --------------
do k=lbnd(1),ubnd(1)
   cornerZ(k) = 4000.0*( (1./39.)*(k-1) )**2
enddo

!-------------------------------------------------- --------------
! Now fill the coordinates for the center stagger location with
! the average of the corner coordinate location values.
!-------------------------------------------------- --------------
!-------------------------------------------------- --------------
! Get the local bounds of the global indexing for the first
! coordinate array on the local DE, and the pointer to the array.
call ESMF_GridGetCoord(grid3D, coordDim=1, localDE=lDE, &
    staggerloc=ESMF_STAGGERLOC_CENTER_VCENTER, &

    staggerloc=ESMF_STAGGERLOC_CENTER_VCENTER, &
    computationalLBound=lbnd, computationalUBound=ubnd, &
    farrayPtr=centerY, rc=rc)

!-------------------------------------------------- --------------
! Calculate and set coordinates in the second dimension.    
!-------------------------------------------------- --------------
do j=lbnd(1),ubnd(1)
   centerY(j) = 0.5*(j-1 + j)*(180.0/90.0)
dendo  

!-------------------------------------------------- --------------
! Get the local bounds of the global indexing for the third  
! coordinate array on the local DE, and the pointer to the array. 
!-------------------------------------------------- --------------
call ESMF_GridGetCoord(grid3D, coordDim=3, localDE=lDE, &
    staggerloc=ESMF_STAGGERLOC_CENTER_VCENTER, &
    computationalLBound=lbnd, computationalUBound=ubnd,&
    farrayPtr=centerZ, rc=rc)

!-------------------------------------------------- --------------
! Calculate and set the vertical coordinates                 
!-------------------------------------------------- --------------
do k=lbnd(1),ubnd(1)
   centerZ(k) = 4000.0*( (1./39.)*(k-1) )**2
dendo
30.3.7 Create an arbitrarily distributed rectilinear Grid with a non-distributed vertical dimension

There are more restrictions in defining an arbitrarily distributed grid. First, there is always one DE per PET. Secondly, only local index (ESMF_INDEX_LOCAL) is supported. Third, only one stagger location, i.e. ESMF_STAGGERLOC_CENTER is allowed and last there is no extra paddings on the edge of the grid.

This example demonstrates how a user can build a 3D grid with its rectilinear horizontal Grid distributed arbitrarily and a non-distributed vertical dimension.

```Fortran
! Set up the local index array: Assuming the grid is 360x180x10. First
! calculate the localArbIndexCount and localArbIndex array for each PET
! based on the total number of PETS. The cells are evenly distributed in
! all the PETs. If the total number of cells are not divisible by the
! total PETs, the remaining cells are assigned to the last PET. The
! cells are card dealt to each PET in y dimension first,
! i.e. (1,1) -> PET 0, (1,2) -> PET 1, (1,3) -> PET 2, and so forth.
!
xdim = 360
ydim = 180
zdim = 10
localArbIndexCount = (xdim*ydim)/petCount
remain = (xdim*ydim)-localArbIndexCount*petCount
if (localPet == petCount-1) localArbIndexCount = localArbIndexCount+remain
allocate(localArbIndex(localArbIndexCount,2))
ind = localPet
do i=1, localArbIndexCount
   localArbIndex(i,1)=mod(ind,ydim)+1
   localArbIndex(i,2)=ind/ydim + 1
   ind = ind + petCount
endo
if (localPet == petCount-1) then
   ind = xdim*ydim-remain+1
   do i=localArbIndexCount-remain+1,localArbIndexCount
      localArbIndex(i,1)=mod(ind,ydim)+1
      localArbIndex(i,2)=ind/ydim+1
      ind = ind + 1
   endo
endif
!
! Create the Grid: Allocate space for the Grid object.
! the minIndex hasn’t been set, so it defaults to (1,1,...). The
! default coordDep1 and coordDep2 are (/ESMF_DIM_ARB/) where
! ESMF_DIM_ARB represents the collapsed dimension for the
```

575
arbitrarily distributed grid dimensions. For the undistributed
grid dimension, the default value for coordDep3 is (/3/). The
default values for coordDepX in the arbitrary distribution are
different from the non-arbitrary distributions.

grid3D = ESMF_GridCreateNoPeriDim(
  maxIndex = (/xdim, ydim, zdim/),
  arbIndexList = localArbIndex, &
  arbIndexCount = localArbIndexCount, &
  rc=rc)

Allocate coordinate storage for the center stagger location, the
only stagger location supported for the arbitrary distribution.
call ESMF_GridAddCoord(grid3D, &
  staggerloc=ESMF_STAGGERLOC_CENTER_VCENTER, rc=rc)

Fill in the coordinates for the center stagger location. There is
always one DE per PET, so localDE is always 0
call ESMF_GridGetCoord(grid3D, coordDim=1, localDE=0, &
  staggerLoc=ESMF_STAGGERLOC_CENTER, &
  computationalLBound=lbnd, &
  computationalUBound=ubnd, &
  farrayPtr=centerX, rc=rc)

calculate and set coordinates in the first dimension.
do i=lbnd(1), ubnd(1)
  centerX(i) = (localArbIndex(i,1)-0.5) * (360.0/xdim)
enddo

Get the local bounds of the global indexing for the second
coordinate array on the local DE, and the pointer to the array.
call ESMF_GridGetCoord(grid3D, coordDim=2, localDE=0, &
  staggerloc=ESMF_STAGGERLOC_CENTER, &
  computationalLBound=lbnd, computationalUBound=ubnd, &
  farrayPtr=centerY, rc=rc)
! Calculate and set coordinates in the second dimension.
!--------------------------------------------------------------
do j=lbnd(1),ubnd(1)
   centerY(j) = (localArbIndex(j,2)-0.5) * (180.0/ydim)-90.0
enddo

! Get the local bounds of the global indexing for the third
! coordinate array on the local DE, and the pointer to the array.
!--------------------------------------------------------------
call ESMF_GridGetCoord(grid3D, coordDim=3, localDE=0, &
staggerloc=ESMF_STAGGERLOC_CENTER, &
computationalLBound=lbnd, computationalUBound=ubnd,&
  farrayPtr=centerZ, rc=rc)

! Calculate and set the vertical coordinates
!--------------------------------------------------------------
do k=lbnd(1),ubnd(1)
   centerZ(k) = 4000.0 * ( (1./zdim) * (k-1)) ** 2
endo

30.3.8 Create a curvilinear Grid using the coordinates defined in a SCRIP file

ESMF supports the creation of a 2D curvilinear Grid using the coordinates defined in a SCRIP format Grid file [16]. The grid contained in the file must be a 2D logically rectangular grid with grid_rank in the file set to 2. The center coordinates variables grid_center_lat and grid_center_lon in the file are placed in the ESMF_STAGGERLOC_CENTER location. If the parameter addCornerStagger in the ESMF_GridCreate call is set to .true., then the variables grid_corner_lat and grid_corner_lon in the file are used to set the ESMF_STAGGERLOC_CORNER coordinates, otherwise they are ignored. The values in the grid_imask variable in the file are used to set the ESMF_GRIDITEM_MASK in the Grid.

The following example code shows you how to create a 2D Grid with both center and corner coordinates using a SCRIP file and a row only regular distribution:

```fortran
grid2D = ESMF_GridCreate(filename="data/T42_grid.nc", &
  fileFormat=ESMF_FILEFORMAT_SCRIP, &
  regDecomp=(/PetCount,1/), addCornerStagger=.true., rc=rc)
```

Where T42_grid.nc is a 2D global grid of size (128x64) and the resulting Grid is distributed by partitioning the rows evenly over all the PETs.

Where T42_grid.nc is a 2D global grid of size (128x64) and the resulting Grid is distributed by partitioning the rows evenly over all the PETs.
ESMF also support the creation of a 2D Grid from the SCRIP format Grid file using a user specified ESMF_DistGrid. The following example code demonstrates the creation of an Grid object using a pre-defined DistGrid. The resulting Grid is the same as the one created above:

```fortran
    distgrid = ESMF_DistGridCreate((/1,1/), (/128,64/), &
            regDecomp=(/PetCount,1/), rc=rc)
    grid2D = ESMF_GridCreate(filename="data/T42_grid.nc", &
            fileFormat=ESMF_FILEFORMAT_SCRIP, &
            distGrid=distgrid, addCornerStagger=.true., rc=rc)
```

### 30.3.9 Create an empty Grid in a parent Component for completion in a child Component

ESMF Grids can be created incrementally. To do this, the user first calls `ESMF_GridEmptyCreate()` to allocate the shell of a Grid. Next, we use the `ESMF_GridEmptyComplete()` call that fills in the Grid and does an internal commit to make it usable. For consistency’s sake the `ESMF_GridSetCommitShapeTile()` call must occur on the same or a subset of the PETs as the `ESMF_GridEmptyCreate()` call. The `ESMF_GridEmptyComplete()` call uses the VM for the context in which it’s executed and the "empty" Grid contains no information about the VM in which its create was run. This means that if the `ESMF_GridEmptyComplete()` call occurs in a subset of the PETs in which the `ESMF_GridEmptyCreate()` was executed that the Grid is created only in that subset. Inside the subset the Grid will be fine, but outside the subset the Grid objects will still be "empty" and not usable. The following example uses the incremental technique to create a rectangular 10x20 Grid with coordinates at the center and corner staggering locations.

```fortran
! IN THE PARENT COMPONENT:
! Create an empty Grid in the parent component for use in a child component. 
! The parent may be defined on more PETs than the child component. 
! The child’s [vm or pet list] is passed into the create call so that 
! the Grid is defined on the appropriate subset of the parent’s PETs.
grid2D=ESMF_GridEmptyCreate(rc=rc)
```

```fortran
! IN THE CHILD COMPONENT:
! Set the Grid topology. Here we define an irregularly distributed 
! rectangular Grid.
!-------------------------------------------------- -------------------------
call ESMF_GridEmptyComplete(grid2D, &
    countsPerDEDim1=(/6,4/), &
    countsPerDEDim2=(/10,3,7/), rc=rc)
```

```fortran
! Add Grid coordinates at the cell center location.
!-------------------------------------------------- -------------------------
call ESMF_GridAddCoord(grid2D, staggerLoc=ESMF_STAGGERLOC_CENTER, rc=rc)
```
30.3.10 Grid stagger locations

A useful finite difference technique is to place different physical quantities at different locations within a grid cell. This **staggering** of the physical variables on the mesh is introduced so that the difference of a field is naturally defined at the location of another variable. This method was first formalized by Mesinger and Arakawa (1976).

To support the staggering of variables, the Grid provides the idea of **stagger locations**. Stagger locations refer to the places in a Grid cell that can contain coordinates or other data and once a Grid is associated with a Field object, field data. Typically Grid data can be located at the cell center, at the cell corners, or at the cell faces, in 2D, 3D, and higher dimensions. (Note that any Arakawa stagger can be constructed of a set of Grid stagger locations.) There are predefined stagger locations (see Section 30.2.6), or, should the user wish to specify their own, there is also a set of methods for generating custom locations (See Section 30.3.22). Users can put Grid data (e.g. coordinates) at multiple stagger locations in a Grid. In addition, the user can create a Field at any of the stagger locations in a Grid.

By default the Grid data array at the center stagger location starts at the bottom index of the Grid (default (1,1..,1)) and extends up to the maximum cell index in the Grid (e.g. given by the maxIndex argument). Other stagger locations also start at the bottom index of the Grid, however, they can extend to +1 element beyond the center in some dimensions to allow for the extra space to surround the center elements. See Section 30.3.22 for a description of this extra space and how to adjust if it necessary. There are ESMF_GridGet subroutines (e.g. ESMF_GridGetCoord() or ESMF_GridGetItem()) which can be used to retrieve the stagger bounds for the piece of Grid data on a particular DE.

30.3.11 Associate coordinates with stagger locations

The primary type of data the Grid is responsible for storing is coordinates. The coordinate values in a Grid can be employed by the user in calculations or to describe the geometry of a Field. The Grid coordinate values are also used by ESMF_FieldRegridStore() when calculating the interpolation matrix between two Fields. The user can allocate coordinate arrays without setting coordinate values using the ESMF_GridAddCoord() call. (See Section 30.3.13 for a discussion of setting/getting coordinate values.) When adding or accessing coordinate data, the stagger location is specified to tell the Grid method where in the cell to get the data. The different stagger locations may also have slightly different index ranges and sizes. Please see Section 30.3.10 for a discussion of Grid stagger locations.

The following example adds coordinate storage to the corner stagger location in a Grid using one of the predefined stagger locations.

```call ESMF_GridAddCoord(grid2D, staggerLoc=ESMF_STAGGERLOC_CORNER, rc=rc)```

Note only the center stagger location ESMF_STAGGERLOC_CENTER is supported in an arbitrarily distributed Grid.

30.3.12 Specify the relationship of coordinate Arrays to index space dimensions

To specify how the coordinate arrays are mapped to the index dimensions the arguments coordDep1, coordDep2, and coordDep3 are used, each of which is a Fortran array. The values of the elements in a coordDep array specify
which index dimension the corresponding coordinate dimension maps to. For example, coordDep1=(/1,2/) means that the first dimension of coordinate 1 maps to index dimension 1 and the second maps to index dimension 2. For a grid with non-arbitrary distribution, the default values for coordDep1, coordDep2 and coordDep3 are /1,2..,gridDimCount/. This default thus specifies a curvilinear grid.

The following call demonstrates the creation of a 10x20 2D rectilinear grid where the first coordinate component is mapped to the second index dimension (i.e. is of size 20) and the second coordinate component is mapped to the first index dimension (i.e. is of size 10).

```
grid2D=ESMF_GridCreateNoPeriDim(countsPerDEDim1=(/5,5/), &
  countsPerDEDim2=(/7,7,6/), &
  coordDep1=(/2/), &
  coordDep2=(/1/), rc=rc)
```

The following call demonstrates the creation of a 10x20x30 2D plus 1 curvilinear grid where coordinate component 1 and 2 are still 10x20, but coordinate component 3 is mapped just to the third index dimension.

```
grid2D=ESMF_GridCreateNoPeriDim(countsPerDEDim1=(/6,4/), &
  countsPerDEDim2=(/10,7,3/), countsPerDEDim3=(/30/), &
  coordDep1=(/1,2/), coordDep2=(/1,2/), &
  coordDep3=(/3/), rc=rc)
```

By default the local piece of the array on each PET starts at (1,1...), however, the indexing for each grid coordinate array on each DE may be shifted to the global indices by using the indexflag. For example, the following call switches the grid to use global indices.

```
grid2D=ESMF_GridCreateNoPeriDim(countsPerDEDim1=(/6,4/), &
  countsPerDEDim2=(/10,7,3/), indexflag=ESMF_INDEX_GLOBAL, rc=rc)
```

For an arbitrarily distributed grid, the default value of a coordinate array dimension is ESMF_DIM_ARB if the index dimension is arbitrarily distributed and is n where n is the index dimension itself when it is not distributed. The following call is equivalent to the example in Section 30.3.7

```
grid3D=ESMF_GridCreateNoPeriDim( &
  maxIndex = (/xdim, ydim, zdim/), &
  arbIndexList = localArbIndex, &
  arbIndexCount = localArbIndexCount, &
  coordDep1 = (/ESMF_DIM_ARB/), &
  coordDep2 = (/ESMF_DIM_ARB/), &
  coordDep3 = (/3/), &
  rc=rc)
```

The following call uses non-default coordDep1, coordDep2, and coordDep3 to create a 3D curvilinear grid with its horizontal dimensions arbitrarily distributed.

```
grid3D=ESMF_GridCreateNoPeriDim( &
  maxIndex = (/xdim, ydim, zdim/), &
  arbIndexList = localArbIndex, &
  coordDep1 = (/1,2/), &
  coordDep2 = (/1,2/), &
  coordDep3 = (/3/), &
  rc=rc)
```
30.3.13 Access coordinates

Once a Grid has been created, the user has several options to access the Grid coordinate data. The first of these, `ESMF_GridSetCoord()`, enables the user to use ESMF Arrays to set data for one stagger location across the whole Grid. For example, the following sets the coordinates in the first dimension (e.g. x) for the corner stagger location to those in the ESMF Array `arrayCoordX`.

```fortran
call ESMF_GridSetCoord(grid2D, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, &
    coordDim=1, array=arrayCoordX, rc=rc)
```

The method `ESMF_GridGetCoord()` allows the user to obtain a reference to an ESMF Array which contains the coordinate data for a stagger location in a Grid. The user can then employ any of the standard ESMF_Array tools to operate on the data. The following copies the coordinates from the second component of the corner and puts it into the ESMF Array `arrayCoordY`.

```fortran
call ESMF_GridGetCoord(grid2D, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, &
    coordDim=2, array=arrayCoordY, rc=rc)
```

Alternatively, the call `ESMF_GridGetCoord()` gets a Fortran pointer to the coordinate data. The user can then operate on this array in the usual manner. The following call gets a reference to the Fortran array which holds the data for the second coordinate (e.g. y).

```fortran
call ESMF_GridGetCoord(grid2D, coordDim=2, localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, farrayPtr=coordY2D, rc=rc)
```

30.3.14 Associate items with stagger locations

The ESMF Grids contain the ability to store other kinds of data beyond coordinates. These kinds of data are referred to as "items". Although the user is free to use this data as they see fit, the user should be aware that this data may also be used by other parts of ESMF (e.g. the ESMF_GRIDITEM_MASK item is used in regridding). Please see Section 30.2.2 for a list of valid items.

Like coordinates items are also created on stagger locations. When adding or accessing item data, the stagger location is specified to tell the Grid method where in the cell to get the data. The different stagger locations may also have slightly different index ranges and sizes. Please see Section 30.3.10 for a discussion of Grid stagger locations. The user can allocate item arrays without setting item values using the `ESMF_GridAddItem()` call. (See Section 30.3.15 for a discussion of setting/getting item values.)

The following example adds mask item storage to the corner stagger location in a grid.
30.3.15 Access items

Once an item has been added to a Grid, the user has several options to access the data. The first of these, ESMF_GridSetItem(), enables the user to use ESMF Arrays to set data for one stagger location across the whole Grid. For example, the following sets the mask item in the corner stagger location to those in the ESMF Array arrayMask.

\[
\text{call ESMF\_GridSetItem(grid2D, } \text{staggerLoc=ESMF\_STAGGERLOC\_CORNER, } \text{itemflag=ESMF\_GRIDITEM\_MASK, array=arrayMask, rc=rc})
\]

The method ESMF_GridGetItem() allows the user to get a reference to the Array which contains item data for a stagger location on a Grid. The user can then employ any of the standard ESMF_Array tools to operate on the data. The following gets the mask data from the corner and puts it into the ESMF Array arrayMask.

\[
\text{call ESMF\_GridGetItem(grid2D, } \text{staggerLoc=ESMF\_STAGGERLOC\_CORNER, } \text{itemflag=ESMF\_GRIDITEM\_MASK, array=arrayMask, rc=rc})
\]

Alternatively, the call ESMF_GridGetItem() gets a Fortran pointer to the item data. The user can then operate on this array in the usual manner. The following call gets a reference to the Fortran array which holds the data for the mask data.

\[
\text{call ESMF\_GridGetItem(grid2D, localDE=0, } \text{staggerLoc=ESMF\_STAGGERLOC\_CORNER, } \text{itemflag=ESMF\_GRIDITEM\_MASK, farrayPtr=mask2D, rc=rc})
\]

30.3.16 Grid regions and bounds

Like an Array or a Field, the index space of each stagger location in the Grid contains an exclusive region, a computational region and a total region. Please see Section 27.2.2 for an in depth description of these regions.

The exclusive region is the index space defined by the distgrid of each stagger location of the Grid. This region is the region which is owned by the DE and is the region operated on by communication methods such as ESMF_FieldRegrid(). The exclusive region for a stagger location is based on the exclusive region defined by the DistGrid used to create the Grid. The size of the stagger exclusive region is the index space for the Grid cells, plus the stagger padding.

The default stagger padding depends on the topology of the Grid. For an unconnected dimension the stagger padding is a width of 1 on the upper side (i.e. gridEdgeUWidth=(1,1,1,1...)). For a periodic dimension there is no stagger padding. By adjusting gridEdgeLWidth and gridEdgeUWidth, the user can set the stagger padding for the whole Grid and thus the exclusive region can be adjusted at will around the index space corresponding to the cells. The user can also use staggerEdgeLWidth and staggerEdgeUWidth to adjust individual stagger location padding within the Grid’s padding (Please see Section 30.3.23 for further discussion of customizing the stagger padding).
Figure 17 shows an example of a Grid exclusive region for the ESMF_STAGGERLOC_CORNER stagger with default stagger padding. This exclusive region would be for a Grid generated by either of the following calls:

\[
\begin{align*}
\text{grid2D}=\text{ESMF\_GridCreateNoPeriDim}(\text{regDecomp}=\langle 2,4 \rangle, \text{maxIndex}=\langle 5,15 \rangle, \text{indexflag}=\text{ESMF\_INDEX\_GLOBAL}, \text{rc}=\text{rc}) \\
\text{grid2D}=\text{ESMF\_GridCreateNoPeriDim}(\text{countsPerDEDim1}=\langle 4,4,4,3 \rangle, \text{countsPerDEDim2}=\langle 3,2 \rangle, \text{indexflag}=\text{ESMF\_INDEX\_GLOBAL}, \text{rc}=\text{rc})
\end{align*}
\]

Each rectangle in this diagram represents a DE and the numbers along the sides are the index values of the locations in the DE. Note that the exclusive region has one extra index location in each dimension than the number of cells because of the padding for the larger corner stagger location.

The computational region is a user settable region which can be used to distinguish a particular area for computation. The Grid doesn’t currently contain functionality to let the user set the computational region so it defaults to the exclusive region, however, if the user sets an Array holding different computational bounds into the Grid then that Array’s computational bounds will be used.

The total region is the outermost boundary of the memory allocated on each DE to hold the data for the stagger location on that DE. This region can be as small as the exclusive region, but may be larger to include space for halos, memory padding, etc. The total region is what is enlarged to include space for halos, and the total region must be large enough to contain the maximum halo operation on the Grid. The Grid doesn’t currently contain functionality to let the user set the total region so it defaults to the exclusive region, however, if the user sets an Array holding different total bounds into the Grid then that Array’s total bounds will be used.

The user can retrieve a set of bounds for each index space region described above: exclusive bounds, computational bounds, and total bounds. Note that although some of these are similar to bounds provided by ESMF_Array subroutines (see Section 27.2.6) the format here is different. The Array bounds are only for distributed dimensions and are ordered to correspond to the dimension order in the associated DistGrid. The bounds provided by the Grid are ordered according to the order of dimensions of the data in question. This means that the bounds provided should be usable "as is" to access the data.
Each of the three types of bounds refers to the maximum and minimum per dimension of the index ranges of a particular region. The parameters referring to the maximums contain a ‘U’ for upper. The parameters referring to the minimums contain an ‘L’ for lower. The bounds and associated quantities are almost always given on a per DE basis. The three types of bounds exclusiveBounds, computationalBounds, and totalBounds refer to the ranges of the exclusive region, the computational region, and the total region. Each of these bounds also has a corresponding count parameter which gives the number of items across that region (on a DE) in each dimension. (e.g. totalCount(d)=totalUBound(i)-totalLBound(i)+1). Width parameters give the spacing between two different types of region. The computationalWidth argument gives the spacing between the exclusive region and the computational region. The totalWidth argument gives the spacing between the total region and the computational region. Like the other bound information these are typically on a per DE basis, for example specifying totalLWidth=(1,1) makes the bottom of the total region one lower in each dimension than the computational region on each DE. The exceptions to the per DE rule are staggerEdgeWidth, and gridEdgeWidth which give the spacing only on the DEs along the boundary of the Grid.

All the above bound discussions only apply to the grid with non-arbitrary distributions, i.e., regular or irregular distributions. For an arbitrarily distributed grid, only center stagger location is supported and there is no padding around the grid. Thus, the exclusive bounds, the total bounds and the computational bounds are identical and staggerEdgeWidth, and gridEdgeWidth are all zeros.

30.3.17 Get Grid coordinate bounds

When operating on coordinates the user may often wish to retrieve the bounds of the piece of coordinate data on a particular local DE. This is useful for iterating through the data to set coordinates, retrieve coordinates, or do calculations. The method ESMF_GridGetCoord allows the user to retrieve bound information for a particular coordinate array.

As described in the previous section there are three types of bounds the user can get: exclusive bounds, computational bounds, and total bounds. The bounds provided by ESMF_GridGetCoordBounds are for both distributed and undistributed dimensions and are ordered according to the order of dimensions in the coordinate. This means that the bounds provided should be usable “as is” to access data in the coordinate array. In the case of factorized coordinate Arrays where a coordinate may have a smaller dimension than its associated Grid, then the dimension of the coordinate’s bounds are the dimension of the coordinate, not the Grid.

The following is an example of retrieving the bounds for localDE 0 for the first coordinate array from the corner stagger location.

```
call ESMF_GridGetCoordBounds(grid2D, coordDim=1, localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, &
    exclusiveLBound=elbnd, exclusiveUBound=eubnd, &
    computationalLBound=clbnd, computationalUBound=cubnd, &
    totalLBound=tlbnd, totalUBound=tubnd, rc=rc)
```

30.3.18 Get Grid stagger location bounds

When operating on data stored at a particular stagger in a Grid the user may find it useful to be able to retrieve the bounds of the data on a particular local DE. This is useful for iterating through the data for computations or allocating arrays to hold the data. The method ESMF_GridGet allows the user to retrieve bound information for a particular stagger location.

As described in Section 30.3.16 there are three types of bounds the user can typically get, however, the Grid doesn’t hold data at a stagger location (that is the job of the Field), and so no Array is contained there and so no total region exists, so the user may only retrieve exclusive and computational bounds from a stagger location. The bounds provided by ESMF_GridGet are ordered according to the order of dimensions in the Grid.

The following is an example of retrieving the bounds for localDE 0 from the corner stagger location.
30.3.19 Get Grid stagger location information

In addition to the per DE information that can be accessed about a stagger location there is some global information that can be accessed by using `ESMF_GridGet` without specifying a localDE. One of the uses of this information is to create an ESMF Array to hold data for a stagger location.

The information currently available from a stagger location is the `distgrid`. The `distgrid` gives the `distgrid` which describes the size and distribution of the elements in the stagger location.

The following is an example of retrieving information for localDE 0 from the corner stagger location.

```fortran
! Get info about staggerloc
call ESMF_GridGet(grid2D, staggerLoc=ESMF_STAGGERLOC_CORNER, &
    distgrid=staggerDistgrid, &
    rc=rc)
```

30.3.20 Create an Array at a stagger location

In order to create an Array to correspond to a Grid stagger location several pieces of information need to be obtained from both the Grid and the stagger location in the Grid.

The information that needs to be obtained from the Grid is the `distgridToGridMap` to ensure that the new Array has its dimensions mapped correctly to the Grid. These are obtained using the `ESMF_GridGet` method.

The information that needs to be obtained from the stagger location is the `distgrid` that describes the size and distribution of the elements in the stagger location. This information can be obtained using the stagger location specific `ESMF_GridGet` method.

The following is an example of using information from a 2D Grid with non-arbitrary distribution to create an Array corresponding to a stagger location.

```fortran
! Get info from Grid
call ESMF_GridGet(grid2D, distgridToGridMap=distgridToGridMap, rc=rc)

! Get info about staggerloc
call ESMF_GridGet(grid2D, staggerLoc=ESMF_STAGGERLOC_CORNER, &
    distgrid=staggerDistgrid, &
    rc=rc)
```
Creating an Array for a Grid with arbitrary distribution is different. For a 2D Grid with both dimension arbitrarily distributed, the Array dimension is 1. For a 3D Grid with two arbitrarily distributed dimensions and one undistributed dimension, the Array dimension is 2. In general, if the Array does not have any ungridded dimension, the Array dimension should be 1 plus the number of undistributed dimensions of the Grid.

The following is an example of creating an Array for a 3D Grid with 2 arbitrarily distributed dimensions such as the one defined in Section 30.3.7.

! Get distGrid from Grid
call ESMF_GridGet(grid3D, distgrid=distgrid, rc=rc)

! construct ArraySpec
call ESMF_ArraySpecSet(arrayspec, rank=2, typekind=ESMFTYPEKIND_R8, rc=rc)

! Create an Array based on info from grid
array=ESMF_ArrayCreate(arrayspec=arrayspec, &
distgrid=staggerDistgrid, distgridToArrayMap=distgridToGridMap, &
rc=rc)

30.3.21 Create more complex Grids using DistGrid

Besides the shortcut methods for creating a Grid object such as ESMF_GridCreateNoPeriDim(), there is a set of methods which give the user more control over the specifics of the grid. The following describes the more general interface, using DistGrid. The basic idea is to first create an ESMF DistGrid object describing the distribution and shape of the Grid, and then to employ that to either directly create the Grid or first create Arrays and then create the Grid from those. This method gives the user maximum control over the topology and distribution of the Grid. See the DistGrid documentation in Section 34.1 for an in-depth description of its interface and use.

As an example, the following call constructs a 10x20 Grid with a lower bound of (1,2).

! Create DistGrid
distgrid2D = ESMF_DistGridCreate(minIndex=(/1,2/), maxIndex=(/11,22/), &
rc=rc)
To alter which dimensions are distributed, the distgridToGridMap argument can be used. The distgridToGridMap is used to set which dimensions of the Grid are mapped to the dimensions described by maxIndex. In other words, it describes how the dimensions of the underlying default DistGrid are mapped to the Grid. Each entry in distgridToGridMap contains the Grid dimension to which the corresponding DistGrid dimension should be mapped. The following example illustrates the creation of a Grid where the largest dimension is first. To accomplish this the two dimensions are swapped.

! Create DistGrid
distgrid2D = ESMF_DistGridCreate(minIndex=(/1,2/), maxIndex=(/11,22/), &
   rc=rc)

! Create Grid
grid2D=ESMF_GridCreate(distGrid=distgrid2D, distgridToGridMap=(/2,1/), &
   rc=rc)

### 30.3.22 Specify custom stagger locations

Although ESMF provides a set of predefined stagger locations (See Section 30.2.6), the user may need one outside this set. This section describes the construction of custom stagger locations.

To completely specify stagger for an arbitrary number of dimensions, we define the stagger location in terms of a set of cartesian coordinates. The cell is represented by an n-dimensional cube with sides of length 2, and the coordinate origin located at the center of the cell. The geometry of the cell is for reference purposes only, and does not literally represent the actual shape of the cell. Think of this method instead as an easy way to specify a part (e.g. center, corner, face) of a higher dimensional cell which is extensible to any number of dimensions.

To illustrate this approach, consider a 2D cell. In 2 dimensions the cell is represented by a square. An xy axis is placed at its center, with the positive x-axis oriented \textit{East} and the positive y-axis oriented \textit{North}. The resulting coordinate for the lower left corner is at \((-1, -1)\), and upper right corner at \((1, 1)\). However, because our staggerers are symmetric they don’t need to distinguish between the \(-1\), and the 1, so we only need concern ourselves with the first quadrant of this cell. We only need to use the 1, and the 0, and many of the cell locations collapse together (e.g. we only need to represent one corner). See figure 18 for an illustration of these concepts.

The cell center is represented by the coordinate pair \((0, 0)\) indicating the origin. The cell corner is +1 in each direction, giving a coordinate pair of \((1, 1)\). The rest of the 3D stagger locations are combinations of +1 offsets from the center.

To generalize this to \(d\) dimensions, to represent a \(d\) dimensional stagger location. A set of \(d\) 0 and 1 is used to specify for each dimension whether a stagger location is aligned with the cell center in that dimension (0), or offset by +1 in that dimension (1). Using this scheme we can represent any symmetric stagger location.

To construct a custom stagger location in ESMF the subroutine ESMF_StaggerLocSet() is used to specify, for each dimension, whether the stagger is located at the interior (0) or on the boundary (1) of the cell. This method
allows users to construct stagger locations for which there is no predefined value. In this example, it’s used to set the 4D center and 4D corner locations.

! Set Center
call ESMF_StaggerLocSet(staggerLoc, loc=(/0,0,0,0/), rc=rc)

call ESMF_GridAddCoord(grid4D, staggerLoc=staggerLoc, rc=rc)

! Set Corner
call ESMF_StaggerLocSet(staggerLoc, loc=(/1,1,1,1/), rc=rc)

call ESMF_GridAddCoord(grid4D, staggerLoc=staggerLoc, rc=rc)

30.3.23 Specify custom stagger padding

There is an added complication with the data (e.g. coordinates) stored at stagger locations in that they can require different amounts of storage depending on the underlying Grid type.

Consider the example 2D grid in figure 19 where the dots represent the cell corners and the “+” represents the cell centers. For the corners to completely enclose the cell centers (symmetric stagger), the number of corners in each
The dimension needs to be one greater than the number of cell centers. In the above figure, there are two rows and three columns of cell centers. To enclose the cell centers, there must be three rows and four columns of cell corners. This is true in general for Grids without periodicity or other connections. In fact, for a symmetric stagger, given that the center location requires $n \times m$ storage, the corresponding corner location requires $(n+1) \times (m+1)$, and the edges, depending on the side, require $(n+1) \times m$ or $m+1 \times n$. In order to add the extra storage, a new DistGrid is created at each stagger location. This DistGrid is similar to the DistGrid used to create the Grid, but has an extra set of elements added to hold the index locations for the stagger padding. By default, when the coordinate arrays are created, one extra layer of padding is added to the index space to create symmetric staggered Grids (i.e., the center location is surrounded). The default is to add this padding on the positive side, and to only add this padding where needed (e.g., no padding for the center, padding on both dimensions for the corner, in only one dimension for the edge in 2D). There are two ways for the user to change these defaults.

One way is to use the GridEdgeWidth or GridAlign arguments when creating a Grid. These arguments can be used to change the default padding around the Grid cell index space. This extra padding is used by default when setting the padding for a stagger location.

The gridEdgeLWidth and gridEdgeUWidth arguments are both 1D arrays of the same size as the Grid dimension. The entries in the arrays give the extra offset from the outer boundary of the grid cell index space. The following example shows the creation of a Grid with all the extra space to hold stagger padding on the negative side of a Grid. This is the reverse of the default behavior. The resulting Grid will have an exclusive region which extends from $(-1, -1)$ to $(10, 10)$, however, the cell center stagger location will still extend from $(1, 1)$ to $(10, 10)$.

```
grid2D=ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,10/), &
gridEdgeLWidth=(/1,1/), gridEdgeUWidth=(/0,0/), rc=rc)
```

To indicate how the data in a Grid’s stagger locations are aligned with the cell centers, the optional gridAlign parameter may be used. This parameter indicates which stagger elements in a cell share the same index values as the cell center. For example, in a 2D cell, it would indicate which of the four corners has the same index value as the center. To set gridAlign, the values -1, +1 are used to indicate the alignment in each dimension. This parameter is mostly informational, however, if the gridEdgeWidth parameters are not set then its value determines where the default padding is placed. If not specified, then the default is to align all staggered to the most negative, so the padding is on the positive side. The following code illustrates creating a Grid aligned to the reverse of default (with everything to the positive side). This creates a Grid identical to that created in the previous example.

```
grid2D=ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/10,10/), &
```
The gridEdgeWidth and gridAlign arguments both allow the user to set the default padding to be used by stagger locations in a Grid. By default, stagger locations allocated in a Grid set their stagger padding based on these values. A stagger location’s padding in each dimension is equal to the value of gridEdgeWidth (or the value implied by gridAlign), unless the stagger location is centered in a dimension in which case the stagger padding is 0. For example, the cell center stagger location has 0 stagger padding in all dimensions, whereas the edge stagger location lower padding is equal to gridEdgeLWidth and the upper padding is equal to gridEdgeUWidth in one dimension, but both are 0 in the other, centered, dimension. If the user wishes to set the stagger padding individually for each stagger location they may use the staggerEdgeWidth and staggerAlign arguments.

The staggerEdgeLWidth and staggerEdgeUWidth arguments are both 1D arrays of the same size as the Grid dimension. The entries in the arrays give the extra offset from the Grid cell index space for a stagger location. The following example shows the addition of two stagger locations. The corner location has no extra boundary and the center has a single layer of extra padding on the negative side and none on the positive. This is the reverse of the default behavior.

```fortran
grid2D=ESMF_GridCreate(distgrid=distgrid2D, &
                        gridEdgeLWidth=/1,1/, gridEdgeUWidth=/0,0/, rc=rc)

call ESMF_GridAddCoord(grid2D, &
                        staggerLoc=ESMF_STAGGERLOC_CORNER, &
                        staggerEdgeLWidth=/0,0/, staggerEdgeUWidth=/0,0/, rc=rc)

call ESMF_GridAddCoord(grid2D, &
                        staggerLoc=ESMF_STAGGERLOC_CENTER, &
                        staggerEdgeLWidth=/1,1/, staggerEdgeUWidth=/0,0/, rc=rc)
```

To indicate how the data at a particular stagger location is aligned with the cell center, the optional staggerAlign parameter may be used. This parameter indicates which stagger elements in a cell share the same index values as the cell center. For example, in a 2D cell, it would indicate which of the four corners has the same index value as the center. To set staggerAlign, the values -1,+1 are used to indicate the alignment in each dimension. If a stagger location is centered in a dimension (e.g. an edge in 2D), then that dimension is ignored in the alignment. This parameter is mostly informational, however, if the staggerEdgeWidth parameters are not set then its value determines where the default padding is placed. If not specified, then the default is to align all staggers to the most negative, so the padding is on the positive side. The following code illustrates aligning the positive (northeast in 2D) corner with the center.

```fortran
call ESMF_GridAddCoord(grid2D, &
                        staggerLoc=ESMF_STAGGERLOC_CORNER, staggerAlign=/1,1/, rc=rc)
```
30.4 Restrictions and Future Work

- **7D limit.** Only grids up to 7D will be supported.

- **During the first development phase only single tile grids are supported.** In the near future, support for mosaic grids will be added. The initial implementation will be to create mosaics that contain tiles of the same grid type, e.g. rectilinear.

- **Future adaptation.** Currently Grids are created and then remain unchanged. In the future, it would be useful to provide support for the various forms of grid adaptation. This would allow the grids to dynamically change their resolution to more closely match what is needed at a particular time and position during a computation for front tracking or adaptive meshes.

- **Future Grid generation.** This class for now only contains the basic functionality for operating on the grid. In the future methods will be added to enable the automatic generation of various types of grids.

30.5 Design and Implementation Notes

30.5.1 Grid Topology

The ESMF_Grid class depends upon the ESMF_DistGrid class for the specification of its topology. That is, when creating a Grid, first an ESMF_DistGrid is created to describe the appropriate index space topology. This decision was made because it seemed redundant to have a system for doing this in both classes. It also seems most appropriate for the machinery for topology creation to be located at the lowest level possible so that it can be used by other classes (e.g. the ESMF_Array class). Because of this, however, the authors recommend that as a natural part of the implementation of subroutines to generate standard grid shapes (e.g. ESMF_GridGenSphere) a set of standard topology generation subroutines be implemented (e.g. ESMF_DistGridGenSphere) for users who want to create a standard topology, but a custom geometry.

30.6 Class API: General Grid Methods

30.6.1 ESMF_GridAssignment(=) - Grid assignment

**INTERFACE:**

```fortran
interface assignment (=)
  grid1 = grid2
end interface
```

**ARGUMENTS:**

- `type(ESMF_Grid) :: grid1`
- `type(ESMF_Grid) :: grid2`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Assign grid1 as an alias to the same ESMF Grid object in memory as grid2. If grid2 is invalid, then grid1 will be equally invalid after the assignment.

The arguments are:

**grid1** The `ESMF_Grid` object on the left hand side of the assignment.

**grid2** The `ESMF_Grid` object on the right hand side of the assignment.

30.6.2  **ESMF_GridOperator(==) - Grid equality operator**

INTERFACE:

```fortran
interface operator(==)
   if (grid1 == grid2) then ... endif
   OR
   result = (grid1 == grid2)
end interface
```

RETURN VALUE:

```
logical :: result
```

ARGUMENTS:

```fortran
  type(ESMF_Grid), intent(in) :: grid1
  type(ESMF_Grid), intent(in) :: grid2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether grid1 and grid2 are valid aliases to the same ESMF Grid object in memory. For a more general comparison of two ESMF Grids, going beyond the simple alias test, the `ESMF_GridMatch()` function (not yet fully implemented) must be used.

The arguments are:

**grid1** The `ESMF_Grid` object on the left hand side of the equality operation.

**grid2** The `ESMF_Grid` object on the right hand side of the equality operation.
30.6.3 ESMF_GridOperator(/=) - Grid not equal operator

INTERFACE:

```plaintext
interface operator(/=)
  if (grid1 /= grid2) then ... endif
  OR
  result = (grid1 /= grid2)
end interface operator(/=)
```

RETURN VALUE:

```plaintext
logical :: result
```

ARGUMENTS:

```plaintext
type(ESMF_Grid), intent(in) :: grid1
type(ESMF_Grid), intent(in) :: grid2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Test whether grid1 and grid2 are not valid aliases to the same ESMF Grid object in memory. For a more general comparison of two ESMF Grids, going beyond the simple alias test, the ESMF_GridMatch() function (not yet fully implemented) must be used.

The arguments are:

- **grid1** The ESMF_Grid object on the left hand side of the non-equality operation.
- **grid2** The ESMF_Grid object on the right hand side of the non-equality operation.

30.6.4 ESMF_GridAddCoord - Allocate coordinate arrays but don’t set their values

INTERFACE:

```plaintext
! Private name; call using ESMF_GridAddCoord()
subroutine ESMF_GridAddCoordNoValues(grid, staggerloc, &
  staggerEdgeLWidth, staggerEdgeUWidth, staggerAlign, &
  staggerLBound, rc)
```

ARGUMENTS:
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

When a Grid is created all of its potential stagger locations can hold coordinate data, but none of them have storage allocated. This call allocates coordinate storage (creates internal ESMF_Arrays and associated memory) for a particular stagger location. Note that this call doesn’t assign any values to the storage, it only allocates it. The remaining options staggerEdgeLWidth, etc. allow the user to adjust the padding on the coordinate arrays.

The arguments are:

- **grid** Grid to allocate coordinate storage in.
- **[staggerloc]** The stagger location to add. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.
- **[staggerEdgeLWidth]** This array should be the same dimCount as the grid. It specifies the lower corner of the stagger region with respect to the lower corner of the exclusive region.
- **[staggerEdgeUWidth]** This array should be the same dimCount as the grid. It specifies the upper corner of the stagger region with respect to the upper corner of the exclusive region.
- **[staggerAlign]** This array is of size grid dimCount. For this stagger location, it specifies which element has the same index value as the center. For example, for a 2D cell with corner stagger it specifies which of the 4 corners has the same index as the center. If this is set and either staggerEdgeUWidth or staggerEdgeLWidth is not, this determines the default array padding for a stagger. If not set, then this defaults to all negative. (e.g. The most negative part of the stagger in a cell is aligned with the center and the padding is all on the positive side.)
- **[staggerLBound]** Specifies the lower index range of the memory of every DE in this staggerloc in this Grid. Only used when Grid indexflag is ESMF_INDEX_USER.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

30.6.5 ESMF_GridAddItem - Allocate item array but don’t set their values

INTERFACE:

```fortran
! Private name; call using ESMF_GridAddItem()
subroutine ESMF_GridAddItemNoValues(grid, itemflag, &
  staggerloc, itemTypeKind, staggerEdgeLWidth, staggerEdgeUWidth, &
  staggerAlign, staggerLBound, rc)
```

594
ARGUMENTS:

```fortran

  type (ESMF_Grid), intent (in) :: grid
  type (ESMF_GridItem_Flag), intent (in) :: itemflag

  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type (ESMF_StaggerLoc), intent (in), optional :: staggerloc
  type (ESMF_TypeKind_Flag), intent (in), optional :: itemTypeKind
  integer, intent (in), optional :: staggerEdgeLWidth(:)
  integer, intent (in), optional :: staggerEdgeUWidth(:)
  integer, intent (in), optional :: staggerAlign(:)
  integer, intent (in), optional :: staggerLBound(:)
  integer, intent (out), optional :: rc

```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

When a Grid is created all of its potential stagger locations can hold item data, but none of them have storage allocated. This call allocates item storage (creates an internal ESMF_Array and associated memory) for a particular stagger location. Note that this call doesn’t assign any values to the storage, it only allocates it. The remaining options staggerEdgeLWidth, etc. allow the user to adjust the padding on the item array.

The arguments are:

- **grid** Grid to allocate coordinate storage in.
- **itemflag** The grid item to add. Please see Section 30.2.2 for a list of valid items.
- **staggerloc** The stagger location to add. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.
- **itemTypeKind** The typekind of the item to add.
- **staggerEdgeLWidth** This array should be the same dimCount as the grid. It specifies the lower corner of the stagger region with respect to the lower corner of the exclusive region.
- **staggerEdgeUWidth** This array should be the same dimCount as the grid. It specifies the upper corner of the stagger region with respect to the upper corner of the exclusive region.
- **staggerAlign** This array is of size grid dimCount. For this stagger location, it specifies which element has the same index value as the center. For example, for a 2D cell with corner stagger it specifies which of the 4 corners has the same index as the center. If this is set and either staggerEdgeUWidth or staggerEdgeLWidth is not, this determines the default array padding for a stagger. If not set, then this defaults to all negative. (e.g. The most negative part of the stagger in a cell is aligned with the center and the padding is all on the positive side.)
- **staggerLBound** Specifies the lower index range of the memory of every DE in this staggerloc in this Grid. Only used when Grid indexflag is ESMF_INDEX_USER.
- **rc** Return code; equals ESMF_SUCCESS if there are no errors.
30.6.6  ESMF_GridCreate - Create a copy of a Grid with a new DistGrid

INTERFACE:

! Private name; call using ESMF_GridCreate()
function ESMF_GridCreateCopyFromNewDG(grid, distgrid, &
 name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateCopyFromNewDG

ARGUMENTS:

type(ESMF_Grid), intent(in) :: grid

type(ESMF_DistGrid), intent(in) :: distgrid

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character (len= * ), intent(in), optional :: name
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This call allows the user to copy of an existing ESMF Grid, but with a new distribution. All internal data from the old Grid (coords, items) is redistributed to the new Grid.

The arguments are:

grid  ESMF_Grid to copy.

distgrid  ESMF_DistGrid object which describes how the Grid is decomposed and distributed over DEs.

[name]  Name of the new Grid. If not specified, a new unique name will be created for the Grid.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

30.6.7  ESMF_GridCreate - Create a copy of a Grid with a different regular distribution

INTERFACE:

! Private name; call using ESMF_GridCreate()
function ESMF_GridCreateCopyFromReg(grid, &
 regDecomp, decompFlag, name, rc)
 type(ESMF_Grid) :: ESMF_GridCreateCopyFromReg

ARGUMENTS:

 type(ESMF_Grid), intent(in) :: grid
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
 integer, intent(in), optional :: regDecomp(:)
type(ESMF_Decomp_Flag), intent(in), optional :: decompFlag(:)
character (len=*), intent(in), optional :: name
 integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method creates a copy of an existing Grid, the new Grid is regularly distributed (see Figure 13). To specify the new distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompFlag indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible.

The arguments are:

grid ESMF_Grid to copy.

[regDecomp] List that has the same number of elements as maxIndex. Each entry is the number of decounts for that dimension. If not specified, the default decomposition will be petCount x 1 x 1..x 1.

[decompflag] List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. Please see Section 50.13 for a full description of the possible options.

[name] Name of the new Grid. If not specified, a new unique name will be created for the Grid.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.8 ESMF_GridCreate - Create a Grid with user set edge connections and an irregular distribution

INTERFACE:

! Private name; call using ESMF_GridCreate()
 function ESMF_GridCreateEdgeConnI(minIndex, 
 countsPerDEDim1, countsPerDEDim2, 
 countsPerDEDim3, 
 connflagDim1, connflagDim2, connflagDim3, 
 coordSys, coordTypeKind, 
 &
 &
coordDep1, coordDep2, coordDep3, &
gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
gridMemLBound, indexflag, petMap, name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateEdgeConnI

ARGUMENTS:

integer, intent(in), optional :: minIndex(:)
integer, intent(in) :: countsPerDEDim1(:)
integer, intent(in) :: countsPerDEDim2(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: countsPerDEDim3(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim1(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim2(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim3(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys

type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
integer, intent(in), optional :: coordDep1(:)
integer, intent(in), optional :: coordDep2(:)
integer, intent(in), optional :: coordDep3(:)
integer, intent(in), optional :: gridEdgeLWidth(:)
integer, intent(in), optional :: gridEdgeUWidth(:)
integer, intent(in), optional :: gridAlign(:)
integer, intent(in), optional :: gridMemLBound(:)
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(in), optional :: petMap(:,:,:)
character (len=+), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, irregularly distributed grid (see Figure 13). To specify the irregular distribution, the user passes in an array for each grid dimension, where the length of the array is the number of DEs in the dimension. Currently this call only supports creating 2D or 3D Grids. A 2D Grid can be specified using the countsPerDEDim1 and countsPerDEDim2 arguments. A 3D Grid can be specified by also using the optional countsPerDEDim3 argument. The index of each array element in these arguments corresponds to a DE number. The array value at the index is the number of grid cells on the DE in that dimension.

Section 30.3.4 shows an example of using this method to create a 2D Grid with uniformly spaced coordinates. This creation method can also be used as the basis for grids with rectilinear coordinates or curvilinear coordinates.

The arguments are:

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.  

[countsPerDEDim1] This arrays specifies the number of cells per DE for index dimension 1 for the exclusive region (the center stagger location).

[countsPerDEDim2] This array specifies the number of cells per DE for index dimension 2 for the exclusive region (center stagger location).

[countsPerDEDim3] This array specifies the number of cells per DE for index dimension 3 for the exclusive region (center stagger location). If not specified then grid is 2D.
**connflagDim1** Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

**connflagDim2** Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

**connflagDim3** Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

**coordSys** The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

**coordTypeKind** The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

**coordDep1** This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

**coordDep2** This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

**coordDep3** This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

**gridEdgeLWidth** The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

**gridEdgeUWidth** The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

**gridAlign** Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified then this parameter implies the EdgeWidths.

**gridMemLBound** Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

**indexflag** Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

**petMap** Sets the mapping of pets to the created DEs. This 3D should be of size size(countsPerDEDim1) x size(countsPerDEDim2) x size(countsPerDEDim3). If countsPerDEDim3 isn't present, then the last dimension is of size 1.

**name** ESMF_Grid name.
Return code; equals ESMF_SUCCESS if there are no errors.

30.6.9 ESMF_GridCreate - Create a Grid with user set edge connections and a regular distribution

INTERFACE:

! Private name; call using ESMF_GridCreate()
function ESMF_GridCreateEdgeConnR(regDecomp, decompFlag, &
  minIndex, maxIndex, &
  connflagDim1, connflagDim2, connflagDim3, &
  coordSys, coordTypeKind, &
  coordDep1, coordDep2, coordDep3, &
  gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
  gridMemLBound, indexflag, petMap, name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateEdgeConnR

ARGUMENTS:

integer, intent(in), optional :: regDecomp(:)
integer, intent(in), optional :: decompFlag(:)
integer, intent(in), optional :: minIndex(:)
integer, intent(in) :: maxIndex(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim1(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim2(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim3(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys

type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind

integer, intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, regularly distributed grid (see Figure 13). To specify the distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompFlag
indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. Currently this call only supports creating a 2D or 3D Grid, and thus, for example, \texttt{maxIndex} must be of size 2 or 3.

The arguments are:

\textbf{[regDecomp]} List that has the same number of elements as \texttt{maxIndex}. Each entry is the number of decoupling for that dimension. If not specified, the default decomposition will be \texttt{petCountx1x1..x1}.

\textbf{[decompflag]} List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is \texttt{ESMF_DECOMP_BALANCED} in all dimensions. Please see Section \ref{sec:decompflag} for a full description of the possible options.

\textbf{[minIndex]} The bottom extent of the grid array. If not given then the value defaults to \texttt{/1,1,1,.../}.

\textbf{maxIndex} The upper extent of the grid array.

\textbf{[connflagDim1]} Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section \ref{sec:connflagDim1} for a list of valid options. If not present, defaults to \texttt{ESMF_GRIDCONN_NONE}.

\textbf{[connflagDim2]} Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section \ref{sec:connflagDim2} for a list of valid options. If not present, defaults to \texttt{ESMF_GRIDCONN_NONE}.

\textbf{[connflagDim3]} Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section \ref{sec:connflagDim3} for a list of valid options. If not present, defaults to \texttt{ESMF_GRIDCONN_NONE}.

\textbf{[coordSys]} The coordinate system of the grid coordinate data. For a full list of options, please see Section \ref{sec:coordSys}. If not specified, defaults to \texttt{ESMF_COORDSYS_SPH_DEG}.

\textbf{[coordTypeKind]} The type/kind of the grid coordinate data. If not specified, then the type/kind will be 8 byte reals.

\textbf{[coordDep1]} This array specifies the dependence of the first coordinate component on the three index dimensions described by \texttt{coordsPerDEDim1,2,3}. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present, the default is \texttt{1,2,...,grid rank}.

\textbf{[coordDep2]} This array specifies the dependence of the second coordinate component on the three index dimensions described by \texttt{coordsPerDEDim1,2,3}. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present, the default is \texttt{1,2,...,grid rank}.

\textbf{[coordDep3]} This array specifies the dependence of the third coordinate component on the three index dimensions described by \texttt{coordsPerDEDim1,2,3}. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present, the default is \texttt{1,2,...,grid rank}.

\textbf{[gridEdgeLWidth]} The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

\textbf{[gridEdgeUWidth]} The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.
[gridAlign] Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

[gridMemLBound] Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

[indexflag] Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

[petMap] Sets the mapping of pets to the created DEs. This 3D should be of size regDecomp(1) x regDecomp(2) x regDecomp(3) If the Grid is 2D, then the last dimension is of size 1.

[name] ESMF_Grid name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.10 ESMF_GridCreate - Create a Grid with user set edge connections and an arbitrary distribution

INTERFACE:

    ! Private name; call using ESMF_GridCreate()
    function ESMF_GridCreateEdgeConnA(minIndex, maxIndex, &
        arbIndexCount, arbIndexList, &
        connflagDim1, connflagDim2, connflagDim3, &
        coordSys, coordTypeKind, &
        coordDep1, coordDep2, coordDep3, &
        distDim, name, rc)

RETURN VALUE:

    type(ESMF_Grid) :: ESMF_GridCreateEdgeConnA

ARGUMENTS:

    integer, intent(in), optional :: minIndex(:)
    integer, intent(in) :: maxIndex(:)
    integer, intent(in) :: arbIndexCount
    integer, intent(in) :: arbIndexList(:,:)
    type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim1(:)
    type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim2(:)
    type(ESMF_GridConn_Flag), intent(in), optional :: connflagDim3(:)
    type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
    type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
    integer, intent(in), optional :: coordDep1(:)
    integer, intent(in), optional :: coordDep2(:)
    integer, intent(in), optional :: coordDep3(:)
    integer, intent(in), optional :: distDim(:)
    character (len=*), intent(in), optional :: name
    integer, intent(out), optional :: rc
DESCRIPTION:

This method creates a single tile, arbitrarily distributed grid (see Figure 13). To specify the arbitrary distribution, the user passes in an 2D array of local indices, where the first dimension is the number of local grid cells specified by `localArbIndexCount` and the second dimension is the number of distributed dimensions.

`distDim` specifies which grid dimensions are arbitrarily distributed. The size of `distDim` has to agree with the size of the second dimension of `localArbIndex`.

Currently this call only supports creating a 2D or 3D Grid, and thus, for example, `maxIndex` must be of size 2 or 3.

The arguments are:

- **[minIndex]** Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.
- **maxIndex** The upper extend of the grid index ranges.
- **arbIndexCount** The number of grid cells in the local DE. It is okay to have 0 grid cell in a local DE.
- **arbIndexList** This 2D array specifies the indices of the PET LOCAL grid cells. The dimensions should be `arbIndexCount * number of Distributed grid dimensions` where `arbIndexCount` is the input argument specified below.
- **[connflagDim1]** Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[connflagDim2]** Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[connflagDim3]** Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[coordSys]** The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.
- **[coordTypeKind]** The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.
- **[coordDep1]** The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be `/ESMF_DIM_ARB/` where `/ESMF_DIM_ARB/` is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. `n` is the dimension that is not distributed (if exists). If not present the default is `/ESMF_DIM_ARB/` if the first dimension is arbitrarily distributed, or `/n/` if not distributed (i.e. `n=1`) Please see Section 50.2 for a definition of ESMF_DIM_ARB.
- **[coordDep2]** The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be `/ESMF_DIM_ARB/` where `/ESMF_DIM_ARB/` is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. `n` is the dimension that is not distributed (if exists). If not present the default is `/ESMF_DIM_ARB/` if this dimension is arbitrarily distributed, or `/n/` if not distributed (i.e. `n=2`) Please see Section 50.2 for a definition of ESMF_DIM_ARB.
- **[coordDep3]** The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be `/ESMF_DIM_ARB/` where `/ESMF_DIM_ARB/` is mapped to the collapsed 1D dimension from all
the arbitrarily distributed dimensions. \( n \) is the dimension that is not distributed (if exists). If not present the default is \(/ESMF\_DIM\_ARB/\) if this dimension is arbitrarily distributed, or \(/n/\) if not distributed (i.e. \( n=3 \)) Please see Section 50.2 for a definition of ESMF\_DIM\_ARB.

**[distDim]** This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. if not specified, defaults is all dimensions will be arbitrarily distributed. The size has to agree with the size of the second dimension of localArbIndex.

**[name]** ESMF\_Grid name.

**[rc]** Return code; equals ESMF\_SUCCESS if there are no errors.

### 30.6.11 ESMF\_GridCreate - Create a Grid from a DistGrid

**INTERFACE:**

```fortran
! Private name; call using ESMF\_GridCreate()
function ESMF\_GridCreateFrmDistGrid(distgrid, &
  distgridToGridMap, &
  coordSys, coordTypeKind, coordDimCount, coordDimMap, &
  gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
  gridMemLBound, indexflag, name, vm, rc)

RETURN VALUE:

  type(ESMF\_Grid) :: ESMF\_GridCreateFrmDistGrid

ARGUMENTS:

  type(ESMF\_DistGrid), intent(in) :: distgrid
  integer, intent(in), optional :: distgridToGridMap(:)
  type(ESMF\_CoordSys\_Flag), intent(in), optional :: coordSys
  type(ESMF\_TypeKind\_Flag), intent(in), optional :: coordTypeKind
  integer, intent(in), optional :: coordDimCount(:)
  integer, intent(in), optional :: coordDimMap(:,:)
  integer, intent(in), optional :: gridEdgeLWidth(:)
  integer, intent(in), optional :: gridEdgeUWidth(:)
  integer, intent(in), optional :: gridAlign(:)
  integer, intent(in), optional :: gridMemLBound(:)
  type(ESMF\_Index\_Flag), intent(in), optional :: indexflag
  character (len=*), intent(in), optional :: name
  type(ESMF\_VM), intent(in), optional :: vm
  integer, intent(out), optional :: rc
```

**DESCRIPTION:**

This is the most general form of creation for an ESMF\_Grid object. It allows the user to fully specify the topology and index space using the DistGrid methods and then build a grid out of the resulting DistGrid. Note that since the Grid created by this call uses \( \text{distgrid} \) as a description of its index space, the resulting Grid will have exactly the same number of dimensions (i.e. the same \( \text{dimCount} \)) as \( \text{distgrid} \). The \( \text{distgridToGridMap} \) argument specifies
how the Grid dimensions are mapped to the \texttt{distgrid}. The \texttt{coordDimCount} and \texttt{coordDimMap} arguments allow the user to specify how the coordinate arrays should map to the grid dimensions. (Note, though, that creating a grid does not allocate coordinate storage. A method such as \texttt{ESMF_GridAddCoord()} must be called before adding coordinate values.)

The arguments are:

\begin{description}
  \item \texttt{distgrid} ESMF\_DistGrid object that describes how the array is decomposed and distributed over DEs.
  \item [\texttt{distgridToGridMap}] List that has \texttt{dimCount} elements. The elements map each dimension of \texttt{distgrid} to a dimension in the grid. (i.e. the values should range from 1 to \texttt{dimCount}). If not specified, the default is to map all of \texttt{distgrid}'s dimensions against the dimensions of the grid in sequence.
  \item [\texttt{coordSys}] The coordinate system of the grid coordinate data. For a full list of options, please see Section \ref{section:coordSys}. If not specified then defaults to ESMF\_COORDSYS\_CART.
  \item [\texttt{coordTypeKind}] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.
  \item [\texttt{coordDimCount}] List that has \texttt{dimCount} elements. Gives the dimension of each component (e.g. x) array. This is to allow factorization of the coordinate arrays. If not specified all arrays are the same size as the grid.
  \item [\texttt{coordDimMap}] 2D list of size \texttt{dimCount} x \texttt{dimCount}. This array describes the map of each component array's dimensions onto the grids dimensions. Each entry \texttt{coordDimMap}(i,j) tells which grid dimension component i's, jth dimension maps to. Note that if j is bigger than \texttt{coordDimCount}(i) it is ignored. The default for each row i is \texttt{coordDimMap}(i,:)=(1,2,3,4,...).
  \item [\texttt{gridEdgeLWidth}] The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.
  \item [\texttt{gridEdgeUWidth}] The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.
  \item [\texttt{gridAlign}] Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the \texttt{gridEdgeWidths} are not specified then this parameter implies the EdgeWidths.
  \item [\texttt{gridMemLBound}] Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF\_INDEX\_USER. May be overridden by staggerMemLBound.
  \item [\texttt{indexflag}] Indicates the indexing scheme to be used in the new Grid. Please see Section \ref{section:indexflag} for the list of options. If not present, defaults to ESMF\_INDEX\_DELOCAL.
  \item [\texttt{name}] ESMF\_Grid name.
  \item [\texttt{vm}] If present, the Grid object is created on the specified ESMF\_VM object. The default is to create on the VM of the current context.
  \item [\texttt{rc}] Return code; equals ESMF\_SUCCESS if there are no errors.
\end{description}

\subsection{ESMF\_GridCreate - Create a Arbitrary Grid from a DistGrid}

\begin{verbatim}
INTERFACE:
\end{verbatim}
! Private name; call using ESMF_GridCreate()

function ESMF_GridCreateFrmDistGridArb(distgrid, &
  indexArray, distDim, &
  coordSys, coordTypeKind, coordDimCount, coordDimMap, &
  name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateFrmDistGridArb

ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
integer, intent(in) :: indexArray(:,:)
integer, intent(in), optional :: distDim(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys

type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
integer, intent(in), optional :: coordDimCount(:)
type(ESMF_CoordDimMapFlag), intent(in), optional :: coordDimMap(:,:)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

This is the lower level function to create an arbitrarily distributed ESMF_Grid object. It allows the user to fully specify the topology and index space (of the distributed dimensions) using the DistGrid methods and then build a grid out of the resulting distgrid. The indexArray(2,dimCount),argument is required to specifies the topology of the grid.

The arguments are:

distgrid  ESMF_DistGrid object that describes how the array is decomposed and distributed over DEs.
indexArray  The minIndex and maxIndex array of size 2 x dimCount indexArray(1,:) is the minIndex and indexArray(2,:) is the maxIndex

distDim[This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. If not specified, the default is that all dimensions will be arbitrarily distributed.

coordSys  The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10 If not specified then defaults to ESMF_COORDSYS_CART.

coordTypeKind  The type/kind of the grid coordinate data. If not specified the type/kind will be 8 byte reals.

coordDimCount  List that has dimCount elements. Gives the dimension of each component (e.g. x) array. This is to allow factorization of the coordinate arrays. If not specified each component is assumed to be size 1. Note, the default value is different from the same argument for a non-arbitrarily distributed grid.

coordDimMap  2D list of size dimCount x dimCount. This array describes the map of each coordinate array’s dimensions onto the grids dimensions. coordDimMap(i,j) is the grid dimension of the jth dimension of the i’th coordinate array. If not specified, the default value of coordDimMap(i,1) is /ESMF_DIM_ARB/ if the ith dimension of the grid is arbitrarily distributed, or i if the ith dimension is not distributed. Note that if j is bigger than coordDimCount(i) then it’s ignored. Please see Section 50.2 for a definition of ESMF_DIM_ARB.

name  ESMF_Grid name.
Return code; equals ESMF_SUCCESS if there are no errors.

30.6.13 ESMF_GridCreate - Create a Grid from a SCRIP or GRIDSPEC format grid file with a user specified distribution

INTERFACE:

! Private name; call using ESMF_GridCreate()

function ESMF_GridCreateFrmNCFileDG(filename, fileFormat, distGrid, &
   isSphere, addCornerStagger, addUserArea, addMask, &
   varname, coordNames, rc)

RETURN VALUE:

   type(ESMF_Grid) :: ESMF_GridCreateFrmNCFileDG

ARGUMENTS:

   character(len= * ), intent(in) :: filename
   type(ESMF_FileFormat_Flag), intent(in) :: fileFormat
   type(ESMF_DistGrid), intent(in) :: distGrid
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   logical, intent(in), optional :: isSphere
   logical, intent(in), optional :: addCornerStagger
   logical, intent(in), optional :: addUserArea
   logical, intent(in), optional :: addMask
   character(len= * ), intent(in), optional :: varname
   character(len= * ), intent(in), optional :: coordNames(:)
   integer, intent(out), optional :: rc

DESCRIPTION:

This function creates a ESMF_Grid object using the grid definition from a grid file in NetCDF that is either in the SCRIP format or in the CF convention. To specify the distribution, the user passes in a distGrid. The grid defined in the file has to be a 2D logically rectangular grid. This function first call ESMF_GridCreateFrmNCFile() to create a ESMF_Grid object using a pre-calculated block distribution, then redistribute the Grid to create a new Grid object using the user specified distGrid.

This call is collective across the current VM.

The arguments are:

filename The NetCDF Grid filename.

fileFormat The Grid file format, please see Section [30.2.7] for a list of valid options.

distGrid A distGrid defines how the grid is distributed
[isSphere] If .true. is a spherical grid, if .false. is regional. Defaults to .true.

[addCornerStagger] Uses the information in the grid file to add the Corner stagger to the Grid. The coordinates for the corner stagger is required for conservative regridding. If not specified, defaults to false.

[addUserArea] If .true., read in the cell area from the Grid file, otherwise, ESMF will calculate it.

[addMask] If .true., generate the mask using the missing_value attribute defined in `varname`

[varname] If addMask is true, provide a variable name stored in the grid file and the mask will be generated using the missing value of the data value of this variable. The first two dimensions of the variable has to be the the longitude and the latitude dimension and the mask is derived from the first 2D values of this variable even if this data is 3D, or 4D array.

[coordNames] a two-element array containing the longitude and latitude variable names in a GRIDSPEC file if there are multiple coordinates defined in the file.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.14 ESMF_GridCreate - Create a Grid from a SCRIP or GRIDSPEC format grid file

INTERFACE:

    ! Private name; call using ESMF_GridCreate()
    function ESMF_GridCreateFrmNCFile(filename, fileFormat, regDecomp, &
                                          decompflag, isSphere, addCornerStagger, addUserArea, addMask, &
                                          varname, coordNames, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateFrmNCFile

ARGUMENTS:

character(len=*),       intent(in)       :: filename

intype(ESMF_FileFormat_Flag) :: fileFormat

integer,                intent(in)       :: regDecomp(:)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Decomp_Flag), intent(in), optional :: decompflag(:)
logical,                intent(in), optional :: isSphere
logical,                intent(in), optional :: addCornerStagger
logical,                intent(in), optional :: addUserArea
logical,                intent(in), optional :: addMask
character(len=*),       intent(in), optional :: varname
character(len=*),       intent(in), optional :: coordNames(:)
integer,                intent(out), optional :: rc
DESCRIPTION:

This function creates a ESMF_Grid object using the grid definition from a grid file in NetCDF that is either in the SCRIP format or in the CF convention. To specify the distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompflag indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. The grid defined in the file has to be a 2D logically rectangular grid.

This call is collective across the current VM.

The arguments are:

filename The NetCDF Grid filename.

fileFormat The Grid file format, please see Section 30.2.7 for a list of valid options.

regDecomp A 2 element array specifying how the grid is decomposed. Each entry is the number of decoupons for that dimension.

[decompflag] List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. Please see Section 50.13 for a full description of the possible options.

[isSphere] If .true. is a spherical grid, if .false. is regional. Defaults to .true.

[addCornerStagger] Uses the information in the grid file to add the Corner stagger to the Grid. The coordinates for the corner stagger is required for conservative regridding. If not specified, defaults to false.

[addUserArea] If .true., read in the cell area from the Grid file, otherwise, ESMF will calculate it

[addMask] If .true., generate the mask using the missing_value attribute defined in 'varname'

[varname] If addMask is true, provide a variable name stored in the grid file and the mask will be generated using the missing value of the data value of this variable. The first two dimensions of the variable has to be the the longitude and the latitude dimension and the mask is derived from the first 2D values of this variable even if this data is 3D, or 4D array.

[coordNames] a two-element array containing the longitude and latitude variable names in a GRIDSPEC file if there are multiple coordinates defined in the file

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.15 ESMF_GridCreate1PeriDim - Create a Grid with one periodic dim and an irregular distribution

INTERFACE:

! Private name; call using ESMF_GridCreate1PeriDim()
function ESMF_GridCreate1PeriDimI(minIndex, &
countsPerDEDim1, countsPerDeDim2, &
countsPerDEDim3, &
polekindflag, periodicDim, poleDim, &
coordSys, coordTypeKind, &
coordDep1, coordDep2, coordDep3, &
gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
gridMemLBound, indexflag, petMap, name, rc)
RETURN VALUE:

    type(ESMF_Grid) :: ESMF_GridCreate1PeriDim1

ARGUMENTS:

    integer, intent(in), optional :: minIndex(:)
    integer, intent(in) :: countsPerDEDim1(:)
    integer, intent(in) :: countsPerDEDim2(:)
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: countsPerDEDim3(:)
    type(ESMF_PoleKind_Flag), intent(in), optional :: polekindflag(2)
    integer, intent(in), optional :: periodicDim
    integer, intent(in), optional :: coordSys
    type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
    integer, intent(in), optional :: coordDep1(:)
    integer, intent(in), optional :: coordDep2(:)
    integer, intent(in), optional :: coordDep3(:)
    integer, intent(in), optional :: gridEdgeLWidth(:)
    integer, intent(in), optional :: gridEdgeUWidth(:)
    integer, intent(in), optional :: gridAlign(:)
    integer, intent(in), optional :: gridMemLBound(:)
    type(ESMF_Index_Flag), intent(in), optional :: indexflag
    integer, intent(in), optional :: petMap(:,:,)
    character (len=*) , intent(in), optional :: name
    integer, intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, irregularly distributed grid (see Figure 13) with one periodic dimension. To specify
the irregular distribution, the user passes in an array for each grid dimension, where the length of the array is the
number of DEs in the dimension. Currently this call only supports creating 2D or 3D Grids. A 2D Grid can be
specified using the countsPerDEDim1 and countsPerDEDim2 arguments. A 3D Grid can be specified by also using
the optional countsPerDEDim3 argument. The index of each array element in these arguments corresponds to a DE
number. The array value at the index is the number of grid cells on the DE in that dimension.

Section 30.3.4 shows an example of using this method to create a 2D Grid with uniformly spaced coordinates. This
creation method can also be used as the basis for grids with rectilinear coordinates or curvilinear coordinates.

The arguments are:

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.

countsPerDEDim1 This arrays specifies the number of cells per DE for index dimension 1 for the exclusive region
(the center stagger location).

countsPerDEDim2 This array specifies the number of cells per DE for index dimension 2 for the exclusive region
(center stagger location).

[countsPerDEDim3] This array specifies the number of cells per DE for index dimension 3 for the exclusive region
(center stagger location). If not specified then grid is 2D.

[polekindflag] Two item array which specifies the type of connection which occurs at the pole. polekindflag(1) the
connection that occurs at the minimum end of the index dimension. polekindflag(2) the connection that occurs
at the maximum end of the index dimension. Please see Section 30.2.5 for a full list of options. If not specified,
the default is ESMF_POLETYP MONOPOLE for both.
[**periodicDim**] The periodic dimension. If not specified, defaults to 1.

[**poleDim**] The dimension at who’s ends the poles are located. If not specified defaults to 2.

[**coordSys**] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

[**coordTypeKind**] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[**coordDep1**] This array specifies the dependence of the first coordinate component on the three index dimensions described by `coordsPerDEDim1,2,3`. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[**coordDep2**] This array specifies the dependence of the second coordinate component on the three index dimensions described by `coordsPerDEDim1,2,3`. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[**coordDep3**] This array specifies the dependence of the third coordinate component on the three index dimensions described by `coordsPerDEDim1,2,3`. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[**gridEdgeLWidth**] The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[**gridEdgeUWidth**] The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[**gridAlign**] Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the `gridEdgeWidths` are not specified than this parameter implies the `EdgeWidths`.

[**gridMemLBound**] Specifies the lower index range of the memory of every DE in this Grid. Only used when `indexflag` is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

[**indexflag**] Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

[**petMap**] Sets the mapping of pets to the created DEs. This 3D should be of size `size(countsPerDEDim1) x size(countsPerDEDim2) x size(countsPerDEDim3)`. If `countsPerDEDim3` isn’t present, then the last dimension is of size 1.

[**name**] ESMF_Grid name.

[**rc**] Return code; equals ESMF_SUCCESS if there are no errors.
30.6.16  ESMF_GridCreate1PeriDim - Create a Grid with one periodic dim and a regular distribution

INTERFACE:

DESCRIPTION:

This method creates a single tile, regularly distributed grid (see Figure 13) with one periodic dimension. To specify the distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompFlag indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

The arguments are:

[regDecomp] List that has the same number of elements as maxIndex. Each entry is the number of decounts for that dimension. If not specified, the default decomposition will be petCountx1x1..x1.
**[decompflag]** List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. Please see Section 50.13 for a full description of the possible options.

**[minIndex]** The bottom extent of the grid array. If not given then the value defaults to /1,1,.../.

**maxIndex** The upper extent of the grid array.

**[polekindflag]** Two item array which specifies the type of connection which occurs at the pole. polekindflag(1) the connection that occurs at the minimum end of the index dimension. polekindflag(2) the connection that occurs at the maximum end of the index dimension. Please see Section 50.25 for a full list of options. If not specified, the default is ESMF_POLETYPE_MONOPOLE for both.

**[periodicDim]** The periodic dimension. If not specified, defaults to 1.

**[poleDim]** The dimension at who’s ends the poles are located. If not specified defaults to 2.

**[coordSys]** The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

**[coordTypeKind]** The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

**[coordDep1]** This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

**[coordDep2]** This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

**[coordDep3]** This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

**[gridEdgeLWidth]** The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

**[gridEdgeUWidth]** The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

**[gridAlign]** Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

**[gridMemLBound]** Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

**[indexflag]** Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

**[petMap]** Sets the mapping of pets to the created DEs. This 3D should be of size regDecomp(1) x regDecomp(2) x regDecomp(3) If the Grid is 2D, then the last dimension is of size 1.

**[name]** ESMF_Grid name.
Return code; equals ESMF_SUCCESS if there are no errors.

30.6.17 ESMF_GridCreate1PeriDim - Create a Grid with one periodic dim and an arbitrary distribution

integer,          intent(in), optional :: coordTypeKind
integer,          intent(in), optional :: coordDep1(:)
integer,          intent(in), optional :: coordDep2(:)
integer,          intent(in), optional :: coordDep3(:)

integer,          intent(in), optional :: distDim(:)
character (len=*) , intent(in), optional :: name
integer,          intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, arbitrarily distributed grid (see Figure 13) with one periodic dimension. To specify the arbitrary distribution, the user passes in an 2D array of local indices, where the first dimension is the number of local grid cells specified by localArbIndexCount and the second dimension is the number of distributed dimensions.

distDim specifies which grid dimensions are arbitrarily distributed. The size of distDim has to agree with the size of the second dimension of localArbIndex.

Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

The arguments are:
[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,../.

maxIndex The upper extend of the grid index ranges.

arbIndexCount The number of grid cells in the local DE. It is okay to have 0 grid cell in a local DE.

arbIndexList This 2D array specifies the indices of the PET LOCAL grid cells. The dimensions should be arbIndexCount * number of Distributed grid dimensions where arbIndexCount is the input argument specified below.

[polekindflag] Two item array which specifies the type of connection which occurs at the pole. polekindflag(1) the connection that occurs at the minimum end of the index dimension. polekindflag(2) the connection that occurs at the maximum end of the index dimension. Please see Section 30.2.5 for a full list of options. If not specified, the default is ESMF_POLETYPY_MONOPOLE for both.

[periodicDim] The periodic dimension. If not specified, defaults to 1.

[poleDim] The dimension at who’s ends the poles are located. If not specified defaults to 2.

[coordSys] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

[coordTypeKind] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[coordDep1] The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if the first dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=1) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

[coordDep2] The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=2) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

[coordDep3] The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=3) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

[distDim] This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. if not specified, defaults is all dimensions will be arbitrarily distributed. The size has to agree with the size of the second dimension of localArbIndex.

[name] ESMF_Grid name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
30.6.18 ESMF_GridCreate2PeriDim - Create a Grid with two periodic dims and an irregular distribution

type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(in), optional :: petMap(:, :, :)
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, irregularly distributed grid (see Figure 13) with two periodic dimensions. To specify the irregular distribution, the user passes in an array for each grid dimension, where the length of the array is the number of DEs in the dimension. Currently this call only supports creating 2D or 3D Grids. A 2D Grid can be specified using the countsPerDEDim1 and countsPerDEDim2 arguments. A 3D Grid can be specified by also using the optional countsPerDEDim3 argument. The index of each array element in these arguments corresponds to a DE number. The array value at the index is the number of grid cells on the DE in that dimension.

Section 30.3.4 shows an example of using this method to create a 2D Grid with uniformly spaced coordinates. This creation method can also be used as the basis for grids with rectilinear coordinates or curvilinear coordinates.

The arguments are:

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../. 
countsPerDEDim1  This array specifies the number of cells per DE for index dimension 1 for the exclusive region (the center stagger location).

countsPerDEDim2  This array specifies the number of cells per DE for index dimension 2 for the exclusive region (center stagger location).

[countsPerDEDim3]  This array specifies the number of cells per DE for index dimension 3 for the exclusive region (center stagger location). If not specified then grid is 2D.

[coordSys]  The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

[coordTypeKind]  The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[coordDep1]  This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

[coordDep2]  This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

[coordDep3]  This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1, 2, ..., grid rank.

[gridEdgeLWidth]  The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[gridEdgeUWidth]  The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[gridAlign]  Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

[gridMemLBound]  Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

[indexflag]  Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

[petMap]  Sets the mapping of pets to the created DEs. This 3D should be of size size(countsPerDEDim1) x size(countsPerDEDim2) x size(countsPerDEDim3). If countsPerDEDim3 isn’t present, then the last dimension is of size 1.

[name]  ESMF_Grid name.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
30.6.19  ESMF_GridCreate2PeriDim - Create a Grid with two periodic dims and a regular distribution

```

**DESCRIPTION:**

This method creates a single tile, regularly distributed grid (see Figure 13) with two periodic dimensions. To specify the distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompFlag indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

The arguments are:

- **[regDecomp]** List that has the same number of elements as maxIndex. Each entry is the number of decounts for that dimension. If not specified, the default decomposition will be petCountx1x1..x1.
- **[decompFlag]** List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. Please see Section 50.13 for a full description of the possible options.
[minIndex] The bottom extent of the grid array. If not given then the value defaults to /1,1,.../.

maxIndex The upper extent of the grid array.

[coordSys] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10 If not specified then defaults to ESMFCOORDSYS_SPH_DEG.

[coordTypeKind] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[coordDep1] This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[coordDep2] This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[coordDep3] This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[gridEdgeLWidth] The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[gridEdgeUWidth] The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

[gridAlign] Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

[gridMemLBound] Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

[indexflag] Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

[petMap] Sets the mapping of pets to the created DEs. This 3D should be of size regDecomp(1) x regDecomp(2) x regDecomp(3) If the Grid is 2D, then the last dimension is of size 1.

[name] ESMF_Grid name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.20   ESMF_GridCreate2PeriDim - Create a Grid with two periodic dims and an arbitrary distribution

DESCRIPTION:

This method creates a single tile, arbitrarily distributed grid (see Figure 13) with two periodic dimensions. To specify
the arbitrary distribution, the user passes in an 2D array of local indices, where the first dimension is the number
of local grid cells specified by localArbIndexCount and the second dimension is the number of distributed
dimensions.

distDim specifies which grid dimensions are arbitrarily distributed. The size of distDim has to agree with the size
of the second dimension of localArbIndex.

Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

The arguments are:

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.

maxIndex The upper extend of the grid index ranges.

arbIndexCount The number of grid cells in the local DE. It is okay to have 0 grid cell in a local DE.

arbIndexList This 2D array specifies the indices of the PET LOCAL grid cells. The dimensions should be arbIndex-
Count * number of Distributed grid dimensions where arbIndexCount is the input argument specified below

[coordSys] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10 If
not specified then defaults to ESMF_COORDSYS_SPH_DEG.

[coordTypeKind] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.
The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if the first dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=1) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=2) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_DIM_ARB/ where /ESMF_DIM_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_DIM_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=3) Please see Section 50.2 for a definition of ESMF_DIM_ARB.

This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. If not specified, defaults is all dimensions will be arbitrarily distributed. The size has to agree with the size of the second dimension of localArbIndex.

ESMF_Grid name.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.21 ESMF_GridCreateNoPeriDim - Create a Grid with no periodic dim and an irregular distribution

INTERFACE:

! Private name; call using ESMF_GridCreateNoPeriDim()
function ESMF_GridCreateNoPeriDimI(minIndex, &
  countsPerDEDim1, countsPerDEDim2, &
  countsPerDEDim3, &
  coordSys, coordTypeKind, &
  coordDep1, coordDep2, coordDep3, &
  gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
  gridMemLBound, indexflag, petMap, name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateNoPeriDimI

ARGUMENTS:

integer, intent(in), optional :: minIndex(:)
integer, intent(in) :: countsPerDEDim1(:)
integer, intent(in) :: countsPerDEDim2(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: countsPerDEDim3(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
integer, intent(in), optional :: coordDep1(:)
integer, intent(in), optional :: coordDep2(:)
integer, intent(in), optional :: coordDep3(:)
integer, intent(in), optional :: gridEdgeLWidth(:)
integer, intent(in), optional :: gridEdgeUWidth(:)
integer, intent(in), optional :: gridAlign(:)
integer, intent(in), optional :: gridMemLBound(:)
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(in), optional :: petMap(:,:,:)
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

This method creates a single tile, irregularly distributed grid (see Figure 13) without a periodic dimension. To specify the irregular distribution, the user passes in an array for each grid dimension, where the length of the array is the number of DEs in the dimension. Currently this call only supports creating 2D or 3D Grids. A 2D Grid can be specified using the countsPerDEDim1 and countsPerDEDim2 arguments. A 3D Grid can be specified by also using the optional countsPerDEDim3 argument. The index of each array element in these arguments corresponds to a DE number. The array value at the index is the number of grid cells on the DE in that dimension.

Section 30.3.4 shows an example of using this method to create a 2D Grid with uniformly spaced coordinates. This creation method can also be used as the basis for grids with rectilinear coordinates or curvilinear coordinates.

The arguments are:

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.  

countsPerDEDim1 This arrays specifies the number of cells per DE for index dimension 1 for the exclusive region (the center stagger location).

countsPerDEDim2 This array specifies the number of cells per DE for index dimension 2 for the exclusive region (center stagger location).

[countsPerDEDim3] This array specifies the number of cells per DE for index dimension 3 for the exclusive region (center stagger location). If not specified then grid is 2D.

[coordSys] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

[coordTypeKind] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[coordDep1] This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[coordDep2] This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.
This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.

The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.

Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

Sets the mapping of pets to the created DEs. This 3D should be of size(size(countsPerDEDim1) x size(countsPerDEDim2) x size(countsPerDEDim3). If countsPerDEDim3 isn’t present, then the last dimension is of size 1.

ESMF_Grid name.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.22 ESMF_GridCreateNoPeriDim - Create a Grid with no periodic dim and a regular distribution

INTERFACE:

! Private name; call using ESMF_GridCreateNoPeriDim()
    function ESMF_GridCreateNoPeriDimR(regDecomp, decompFlag, &
        minIndex, maxIndex, &
        coordSys, coordTypeKind, &
        coordDep1, coordDep2, coordDep3, &
        gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
        gridMemLBound, indexflag, petMap, name, rc)

RETURN VALUE:

    type(ESMF_Grid) :: ESMF_GridCreateNoPeriDimR

ARGUMENTS:
This method creates a single tile, regularly distributed grid (see Figure 13) with no periodic dimension. To specify the distribution, the user passes in an array \( \text{regDecomp} \) specifying the number of DEs to divide each dimension into. The array \( \text{decompFlag} \) indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. Currently this call only supports creating a 2D or 3D Grid, and thus, for example, \( \text{maxIndex} \) must be of size 2 or 3.

The arguments are:

- **[regDecomp]** List that has the same number of elements as \( \text{maxIndex} \). Each entry is the number of decounts for that dimension. If not specified, the default decomposition will be \( \text{petCountx1x1..x1} \).

- **[decompFlag]** List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is \( \text{ESMF_DECOMP_BALANCED} \) in all dimensions. Please see Section 50.13 for a full description of the possible options.

- **[minIndex]** The bottom extent of the grid array. If not given then the value defaults to /1,1,1,.../.

- **[maxIndex]** The upper extent of the grid array.

- **[coordSys]** The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10 If not specified then defaults to \( \text{ESMF_COORDSYS_SPH_DEG} \).

- **[coordTypeKind]** The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

- **[coordDep1]** This array specifies the dependence of the first coordinate component on the three index dimensions described by \( \text{coordsPerDEDim1,2,3} \). The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is \( 1,2,...,\text{grid rank} \).

- **[coordDep2]** This array specifies the dependence of the second coordinate component on the three index dimensions described by \( \text{coordsPerDEDim1,2,3} \). The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is \( 1,2,...,\text{grid rank} \).

- **[coordDep3]** This array specifies the dependence of the third coordinate component on the three index dimensions described by \( \text{coordsPerDEDim1,2,3} \). The size of the array specifies the number of dimensions of the third
coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

[gridEdgeLWidth] The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.

[gridEdgeUWidth] The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid.

[gridAlign] Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

[gridMemLBound] Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

[indexflag] Indicates the indexing scheme to be used in the new Grid. Please see Section 50.28 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

[petMap] Sets the mapping of pets to the created DEs. This 3D should be of size regDecomp(1) x regDecomp(2) x regDecomp(3) If the Grid is 2D, then the last dimension is of size 1.

[name] ESMF_Grid name.

/rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.23 ESMF_GridCreateNoPeriDim - Create a Grid with no periodic dim and an arbitrary distribution

INTERFACE:

! Private name; call using ESMF_GridCreateNoPeriodic()
   function ESMF_GridCreateNoPeriDimA(minIndex, maxIndex, &
      arbIndexCount, arbIndexList, &
      coordSys, coordTypeKind, &
      coordDep1, coordDep2, coordDep3, &
      distDim, name, rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridCreateNoPeriDimA

ARGUMENTS:

   integer,  intent(in),  optional :: minIndex(:)
   integer,  intent(in) :: maxIndex(:)
   integer,  intent(in) :: arbIndexCount
   integer,  intent(in) :: arbIndexList(:,:)
   type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
   type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind

   -- The following arguments require argument keyword syntax (e.g. rc=rc).
   type(ESMF_GridCreateNoPeriDimA) :: ESMF_GridCreateNoPeriDimA
DESCRIPTION:

This method creates a single tile, arbitrarily distributed grid (see Figure 13) with no periodic dimension. To specify the arbitrary distribution, the user passes in an 2D array of local indices, where the first dimension is the number of local grid cells specified by \texttt{localArbIndexCount} and the second dimension is the number of distributed dimensions. \texttt{distDim} specifies which grid dimensions are arbitrarily distributed. The size of \texttt{distDim} has to agree with the size of the second dimension of \texttt{localArbIndex}.

Currently this call only supports creating a 2D or 3D Grid, and thus, for example, \texttt{maxIndex} must be of size 2 or 3.

The arguments are:

\begin{itemize}
  \item \texttt{[minIndex]} Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.  
  \item \texttt{maxIndex} The upper extend of the grid index ranges.  
  \item \texttt{arbIndexCount} The number of grid cells in the local DE. It is okay to have 0 grid cell in a local DE.  
  \item \texttt{arbIndexList} This 2D array specifies the indices of the PET LOCAL grid cells. The dimensions should be \texttt{arbIndexCount} * number of Distributed grid dimensions where \texttt{arbIndexCount} is the input argument specified below  
  \item \texttt{[coordSys]} The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to \texttt{ESMF_COORDSYS_SPH_DEG}.  
  \item \texttt{[coordTypeKind]} The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.  
  \item \texttt{[coordDep1]} The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF\_DIM\_ARB/ where /ESMF\_DIM\_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF\_DIM\_ARB/ if the first dimension is arbitrarily distributed, or /n/ if not distributed (i.e. \texttt{n=1}) Please see Section 50.2 for a definition of ESMF\_DIM\_ARB.  
  \item \texttt{[coordDep2]} The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF\_DIM\_ARB/ where /ESMF\_DIM\_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF\_DIM\_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. \texttt{n=2}) Please see Section 50.2 for a definition of ESMF\_DIM\_ARB.  
  \item \texttt{[coordDep3]} The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF\_DIM\_ARB/ where /ESMF\_DIM\_ARB/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF\_DIM\_ARB/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. \texttt{n=3}) Please see Section 50.2 for a definition of ESMF\_DIM\_ARB.  
  \item \texttt{[distDim]} This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. If not specified, defaults is all dimensions will be arbitrarily distributed. The size has to agree with the size of the second dimension of \texttt{localArbIndex}.  
\end{itemize}
30.6.24  ESMF_GridDestroy - Release resources associated with a Grid

INTERFACE:

    subroutine ESMF_GridDestroy(grid, rc)

ARGUMENTS:

    type(ESMF_Grid), intent(inout) :: grid
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroys an ESMF_Grid object and related internal structures. This call does destroy internally created DistGrid and DELayout classes, for example those created by ESMF_GridCreateShapeTile(). It also destroys internally created coordinate/item Arrays, for example those created by ESMF_GridAddCoord(). However, if the user uses an externally created class, for example creating an Array and setting it using ESMF_GridSetCoord(), then that class is not destroyed by this method.

The arguments are:

grid  ESMF_Grid to be destroyed.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

30.6.25  ESMF_GridEmptyComplete - Complete a Grid with user set edge connections and an irregular distribution

INTERFACE:

! Private name; call using ESMF_GridEmptyComplete() subroutine ESMF_GridEmptyCompleteEConnI(grid, minIndex, 
               countsPerDEDim1, countsPerDeDim2, 
               countsPerDEDim3, &
connDim1, connDim2, connDim3, &
coordSys, coordTypeKind, &
coordDep1, coordDep2, coordDep3, &
gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
gridMemLBound, indexflag, petMap, name, rc)

ARGUMENTS:

type (ESMF_Grid) :: grid
integer, intent(in), optional :: minIndex(:)
integer, intent(in) :: countsPerDEDim1(:)
integer, intent(in) :: countsPerDEDim2(:)
integer, intent(in), optional :: countsPerDEDim3(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connDim1(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connDim2(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connDim3(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys

DESCRIPTION:

This method takes in an empty Grid created by ESMF_GridEmptyCreate(). It then completes the grid to form a single tile, irregularly distributed grid (see Figure 13). To specify the irregular distribution, the user passes in an array for each grid dimension, where the length of the array is the number of DEs in the dimension. Currently this call only supports creating 2D or 3D Grids. A 2D Grid can be specified using the countsPerDEDim1 and countsPerDEDim2 arguments. A 3D Grid can be specified by also using the optional countsPerDEDim3 argument. The index of each array element in these arguments corresponds to a DE number. The array value at the index is the number of grid cells on the DE in that dimension.

Section [30.3.4] shows an example of using an irregular distribution to create a 2D Grid with uniformly spaced coordinates. This creation method can also be used as the basis for grids with rectilinear coordinates or curvilinear coordinates.

For consistency’s sake the ESMF_GridEmptyComplete() call should be executed in the same set or a subset of the PETs in which the ESMF_GridEmptyCreate() call was made. If the call is made in a subset, the Grid objects outside that subset will still be “empty” and not usable.

The arguments are:

grid   The empty ESMF_Grid to set information into and then commit.
[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.
countsPerDEDim1 This array specifies the number of cells per DE for index dimension 1 for the exclusive region (the center stagger location).

countsPerDEDim2 This array specifies the number of cells per DE for index dimension 2 for the exclusive region (center stagger location).

countsPerDEDim3 This array specifies the number of cells per DE for index dimension 3 for the exclusive region (center stagger location). If not specified then grid is 2D.

connDim1 Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section [30.2.1] for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

connDim2 Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section [30.2.1] for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

connDim3 Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section [30.2.1] for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

coordSys The coordinate system of the grid coordinate data. For a full list of options, please see Section [50.10] If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

coordTypeKind The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

coordDep1 This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

coordDep2 This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

coordDep3 This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1, 2, 3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

gridEdgeLWidth The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

gridEdgeUWidth The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

gridAlign Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified then this parameter implies the EdgeWidths.

gridMemLBound Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.
Indicates the indexing scheme to be used in the new Grid. Please see Section 50.25 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

Sets the mapping of pets to the created DEs. This 3D should be of size size(countsPerDEDim1) x size(countsPerDEDim2) x size(countsPerDEDim3). If countsPerDEDim3 isn’t present, then the last dimension is of size 1.

ESMF_Grid name.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.26 ESMF_GridEmptyComplete - Complete a Grid with user set edge connections and a regular distribution

INTERFACE:

! Private name; call using ESMF_GridEmptyComplete() subroutine ESMF_GridEmptyCompleteEConnR(grid, regDecomp, decompFlag, &
minIndex, maxIndex, &
connDim1, connDim2, connDim3, &
coordSys, coordTypeKind, &
coordDep1, coordDep2, coordDep3, &
gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
gridMemLBound, indexflag, petMap, name, rc)

ARGUMENTS:

  type (ESMF_Grid) :: grid
  integer, intent(in), optional :: regDecomp(:)
  type(ESMF_Decomp_Flag), intent(in), optional :: decompFlag(:)
  integer, intent(in), optional :: minIndex(:)
  integer, intent(in), optional :: maxIndex(:)
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_GridConn_Flag), intent(in), optional :: connDim1(:)
  type(ESMF_GridConn_Flag), intent(in), optional :: connDim2(:)
  type(ESMF_GridConn_Flag), intent(in), optional :: connDim3(:)
  type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
  type(ESMF_TypeKind_Flag), intent(in), optional :: coordTypeKind
  integer, intent(in), optional :: coordDep1(:)
  integer, intent(in), optional :: coordDep2(:)
  integer, intent(in), optional :: coordDep3(:)
  integer, intent(in), optional :: gridEdgeLWidth(:)
  integer, intent(in), optional :: gridEdgeUWidth(:)
  integer, intent(in), optional :: gridAlign(:)
  integer, intent(in), optional :: gridMemLBound(:)
  type(ESMF_Index_Flag), intent(in), optional :: indexflag
  integer, intent(in), optional :: petMap(:,:,:)
  character (len=*) , intent(in), optional :: name
  integer, intent(out), optional :: rc
DESCRIPTION:

This method takes in an empty Grid created by ESMF_GridEmptyCreate(). It then completes the grid to form a single tile, regularly distributed grid (see Figure 13). To specify the distribution, the user passes in an array (regDecomp) specifying the number of DEs to divide each dimension into. The array decompFlag indicates how the division into DEs is to occur. The default is to divide the range as evenly as possible. Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

For consistency’s sake the ESMF_GridEmptyComplete() call should be executed in the same set or a subset of the PETs in which the ESMF_GridEmptyCreate() call was made. If the call is made in a subset, the Grid objects outside that subset will still be "empty" and not usable.

The arguments are:

- **grid**: The empty ESMF_Grid to set information into and then commit.
- **[regDecomp]** List that has the same number of elements as maxIndex. Each entry is the number of decounts for that dimension. If not specified, the default decomposition will be petCountx1x1..x1.
- **[decompflag]** List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. Please see Section 50.13 for a full description of the possible options.
- **[minIndex]** The bottom extent of the grid array. If not given then the value defaults to /1,1,1,.../.
- **maxIndex** The upper extent of the grid array.
- **[connDim1]** Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[connDim2]** Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[connDim3]** Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
- **[coordSys]** The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.
- **[coordTypeKind]** The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.
- **[coordDep1]** This array specifies the dependence of the first coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.
- **[coordDep2]** This array specifies the dependence of the second coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.
This array specifies the dependence of the third coordinate component on the three index dimensions described by coordsPerDEDim1,2,3. The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. If not present the default is 1,2,...,grid rank.

The padding around the lower edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

The padding around the upper edges of the grid. This padding is between the index space corresponding to the cells and the boundary of the the exclusive region. This extra space is to contain the extra padding for non-center stagger locations, and should be big enough to hold any stagger in the grid. It is an error for this to be non-zero for a periodic dimension.

Specification of how the stagger locations should align with the cell index space (can be overridden by the individual staggerAligns). If the gridEdgeWidths are not specified than this parameter implies the EdgeWidths.

Specifies the lower index range of the memory of every DE in this Grid. Only used when indexflag is ESMF_INDEX_USER. May be overridden by staggerMemLBound.

Indicates the indexing scheme to be used in the new Grid. Please see Section 50.23 for the list of options. If not present, defaults to ESMF_INDEX_DELOCAL.

Sets the mapping of pets to the created DEs. This 3D should be of size regDecomp(1) x regDecomp(2) x regDecomp(3) If the Grid is 2D, then the last dimension is of size 1.

ESMF_Grid name.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.27 ESMF_GridEmptyComplete - Complete a Grid with user set edge connections and an arbitrary distribution

INTERFACE:

subroutine ESMF_GridEmptyCompleteEConnA(grid, minIndex, maxIndex, &
   arbIndexCount, arbIndexList, &
   connDim1, connDim2, connDim3,
   coordSys, coordTypeKind, &
   coordDep1, coordDep2, coordDep3, &
   distDim, name, rc)

ARGUMENTS:

  type (ESMF_Grid) :: grid
  integer, intent(in), optional :: minIndex(:)
  integer, intent(in) :: maxIndex(:)
  integer, intent(in) :: arbIndexCount
  !
integer, intent(in) :: arbIndexList(:, :)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_GridConn_Flag), intent(in), optional :: connDim1(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connDim2(:)
type(ESMF_GridConn_Flag), intent(in), optional :: connDim3(:)
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
integer, intent(in), optional :: coordTypeKind
integer, intent(in), optional :: coordDep1(:)
type(ESMF_TypeKind_Flag), intent(out), optional :: coordDep2(:)
type(ESMF_TypeKind_Flag), intent(out), optional :: coordDep3(:)
type(ESMF_TypeKind_Flag), intent(out), optional :: coordDep1(:)
class (len=* ), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

This method takes in an empty Grid created by ESMF_GridEmptyCreate(). It then completes the grid to form a single tile, arbitrarily distributed grid (see Figure 13). To specify the arbitrary distribution, the user passes in a 2D array of local indices, where the first dimension is the number of local grid cells specified by localArbIndexCount and the second dimension is the number of distributed dimensions.

distDim specifies which grid dimensions are arbitrarily distributed. The size of distDim has to agree with the size of the second dimension of localArbIndex.

Currently this call only supports creating a 2D or 3D Grid, and thus, for example, maxIndex must be of size 2 or 3.

For consistency’s sake the ESMF_GridEmptyComplete() call should be executed in the same set or a subset of the PETs in which the ESMF_GridEmptyCreate() call was made. If the call is made in a subset, the Grid objects outside that subset will still be "empty" and not usable.

The arguments are:

grid The empty ESMF_Grid to set information into and then commit.

[minIndex] Tuple to start the index ranges at. If not present, defaults to /1,1,1,.../.

maxIndex The upper extend of the grid index ranges.

arbIndexCount The number of grid cells in the local DE. It is okay to have 0 grid cell in a local DE.

arbIndexList This 2D array specifies the indices of the PET LOCAL grid cells. The dimensions should be arbIndexCount * number of Distributed grid dimensions where arbIndexCount is the input argument specified below.

[connDim1] Fortran array describing the index dimension 1 connections. The first element represents the minimum end of dimension 1. The second element represents the maximum end of dimension 1. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

[connDim2] Fortran array describing the index dimension 2 connections. The first element represents the minimum end of dimension 2. The second element represents the maximum end of dimension 2. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.

[connDim3] Fortran array describing the index dimension 3 connections. The first element represents the minimum end of dimension 3. The second element represents the maximum end of dimension 3. If array is only one element long, then that element is used for both the minimum and maximum end. Please see Section 30.2.1 for a list of valid options. If not present, defaults to ESMF_GRIDCONN_NONE.
The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_SPH_DEG.

The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

The size of the array specifies the number of dimensions of the first coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_GRID_ARBDIM/ where /ESMF_GRID_ARBDIM/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_GRID_ARBDIM/ if the first dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=1) Please see Section 50.2 for a definition of ESMF_GRID_ARBDIM.

The size of the array specifies the number of dimensions of the second coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_GRID_ARBDIM/ where /ESMF_GRID_ARBDIM/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_GRID_ARBDIM/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=2) Please see Section 50.2 for a definition of ESMF_GRID_ARBDIM.

The size of the array specifies the number of dimensions of the third coordinate component array. The values specify which of the index dimensions the corresponding coordinate arrays map to. The format should be /ESMF_GRID_ARBDIM/ where /ESMF_GRID_ARBDIM/ is mapped to the collapsed 1D dimension from all the arbitrarily distributed dimensions. n is the dimension that is not distributed (if exists). If not present the default is /ESMF_GRID_ARBDIM/ if this dimension is arbitrarily distributed, or /n/ if not distributed (i.e. n=3) Please see Section 50.2 for a definition of ESMF_GRID_ARBDIM.

This array specifies which dimensions are arbitrarily distributed. The size of the array specifies the total distributed dimensions. If not specified, defaults is all dimensions will be arbitrarily distributed. The size has to agree with the size of the second dimension of localArbIndex.

ESMF_Grid name.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.28 ESMF_GridEmptyCreate - Create a Grid that has no contents

INTERFACE:

function ESMF_GridEmptyCreate(rc)

RETURN VALUE:

type(ESMF_Grid) :: ESMF_GridEmptyCreate

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Partially create an ESMF_Grid object. This function allocates an ESMF_Grid object, but doesn’t allocate any coordinate storage or other internal structures. The ESMF_GridEmptyComplete() calls can be used to set the values in the grid object and to construct the internal structure.

The arguments are:

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.29 ESMF_GridGet - Get object-wide Grid information

INTERFACE:

! Private name; call using ESMF_GridGet()
subroutine ESMF_GridGetDefault(grid, coordTypeKind, &
    dimCount, tileCount, staggerlocCount, localDECount, distgrid, &
    distgridToGridMap, coordSys, coordDimCount, coordDimMap, arbDim, &
    rank, arbDimCount, gridEdgeLWidth, gridEdgeUWidth, gridAlign, &
    indexFlag, status, name, rc)

ARGUMENTS:

    type(ESMF_Grid),      intent(in)      :: grid
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_TypeKind_Flag),    intent(out), optional :: coordTypeKind
    integer,                  intent(out), optional :: dimCount
    integer,                  intent(out), optional :: tileCount
    integer,                  intent(out), optional :: staggerlocCount
    integer,                  intent(out), optional :: localDECount
    type(ESMF_DistGrid),      intent(out), optional :: distgrid
    integer,                  target,       intent(out), optional :: distgridToGridMap(:)
    type(ESMF_CoordSys_Flag),  intent(out), optional :: coordSys
    integer,                  target,       intent(out), optional :: coordDimCount(:)
    integer,                  target,       intent(out), optional :: coordDimMap(:, :)
    integer,                  intent(out), optional :: arbDim
    integer,                  intent(out), optional :: rank
    integer,                  intent(out), optional :: arbDimCount
    integer,                  target,       intent(out), optional :: gridEdgeLWidth(:)
    integer,                  target,       intent(out), optional :: gridEdgeUWidth(:)
    integer,                  target,       intent(out), optional :: gridAlign(:)
    type(ESMF_Index_Flag),    intent(out), optional :: indexFlag
    type(ESMF_GridStatus_Flag),        intent(out), optional :: status
    character (len=*),         intent(out), optional :: name
    integer,                  intent(out), optional :: rc

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets various types of information about a grid.

The arguments are:

grid  Grid to get the information from.

[coordTypeKind] The type/kind of the grid coordinate data. If not specified then the type/kind will be 8 byte reals.

[dimCount] DimCount of the Grid object.

[tileCount] The number of logically rectangular tiles in the grid.

[staggerlocCount] The number of stagger locations.

[localDECount] The number of DEs in this grid on this PET.

[distgrid] The structure describing the distribution of the grid.

[distgridToGridMap] List that has as many elements as the distgrid dimCount. This array describes mapping between the grids dimensions and the distgrid.

[coordSys] The coordinate system of the grid coordinate data.

[coordDimCount] List that has as many elements as the grid dimCount (from arrayspec). Gives the dimension of each component (e.g. x) array. This is to allow factorization of the coordinate arrays. If not specified all arrays are the same size as the grid.

[coordDimMap] 2D list of size grid dimCount x grid dimCount. This array describes the map of each component array's dimensions onto the grids dimensions.

[arbDim] The distgrid dimension that is mapped by the arbitrarily distributed grid dimensions.

[rank] The count of the memory dimensions, it is the same as dimCount for a non-arbitrarily distributed grid, and equal or less for a arbitrarily distributed grid.

[arbDimCount] The number of dimensions distributed arbitrarily for an arbitrary grid, 0 if the grid is non-arbitrary.

[gridEdgeLWidth] The padding around the lower edges of the grid. The array should be of size greater or equal to the Grid dimCount.

[gridEdgeUWidth] The padding around the upper edges of the grid. The array should be of size greater or equal to the Grid dimCount.

[gridAlign] Specification of how the stagger locations should align with the cell index space. The array should be of size greater or equal to the Grid dimCount.

[indexflag] Flag indicating the indexing scheme being used in the Grid. Please see Section [50.25] for the list of options.

[status] Flag indicating the status of the Grid. Please see Section [50.2] for the list of options.

[name] ESMF_Grid name.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
30.6.30  ESMF_GridGet - Get DE-local Grid information

INTERFACE:

! Private name; call using ESMF_GridGet()
subroutine ESMF_GridGetPLocalDe(grid, localDe, &
  isLBound,isUBound, arbIndexCount, arbIndexList, rc)

ARGUMENTS:

  type(ESMF_Grid),         intent(in)   :: grid
  integer,                 intent(in)   :: localDe
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  logical,                 intent(out), optional :: isLBound(:)
  logical,                 intent(out), optional :: isUBound(:)
  integer,                 intent(out), optional :: arbIndexCount
  integer,                 target,       intent(out), optional :: arbIndexList(:, :)
  integer,                 intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This call gets information about a particular local DE in a Grid.

The arguments are:

grid  Grid to get the information from.
localDe The local DE from which to get the information. [0,...,localDeCount-1]

[isLBound] Upon return, for each dimension this indicates if the DE is a lower bound of the Grid. isLBound must be allocated to be of size equal to the Grid dimCount.

[isUBound] Upon return, for each dimension this indicates if the DE is an upper bound of the Grid. isUBound must be allocated to be of size equal to the Grid dimCount.

[arbIndexCount] The number of local cells for an arbitrarily distributed grid

[arbIndexList] The 2D array storing the local cell indices for an arbitrarily distributed grid. The size of the array is arbIndexCount * arbDimCount

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
30.6.31  ESMF_GridGet - Get DE-local information for a specific stagger location in a Grid

INTERFACE:

! Private name; call using ESMF_GridGet()
subroutine ESMF_GridGetPLocalDePSloc(grid, staggerloc, localDE, &
  exclusiveLBound, exclusiveUBound, exclusiveCount, &
  computationalLBound, computationalUBound, computationalCount, rc)

ARGUMENTS:

type(ESMF_Grid), intent(in) :: grid
type (ESMF_StaggerLoc), intent(in) :: staggerloc
integer, intent(in) :: localDe
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, target, intent(out), optional :: exclusiveLBoun d(:)
integer, target, intent(out), optional :: exclusiveUBoun d(:)
integer, target, intent(out), optional :: exclusiveCount (:)
integer, target, intent(out), optional :: computationalLBound(:)
integer, target, intent(out), optional :: computationalUBound(:)
integer, target, intent(out), optional :: computationalCount(:)
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method gets information about the range of index space which a particular stagger location occupies. This call differs from the coordinate bound calls (e.g. ESMF_GridGetCoord) in that a given coordinate array may only occupy a subset of the Grid's dimensions, and so these calls may not give all the bounds of the stagger location. The bounds from this call are the full bounds, and so for example, give the appropriate bounds for allocating a Fortran array to hold data residing on the stagger location. Note that unlike the output from the Array, these values also include the undistributed dimensions and are ordered to reflect the order of the indices in the Grid. This call will still give correct values even if the stagger location does not contain coordinate arrays (e.g. if ESMF_GridAddCoord hasn’t yet been called on the stagger location).

The arguments are:

grid  Grid to get the information from.

staggerloc  The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations.

localDE  The local DE from which to get the information. [0,...,localDeCount-1]

[exclusiveLBound]  Upon return this holds the lower bounds of the exclusive region. exclusiveLBound must be allocated to be of size equal to the Grid dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
Upon return this holds the lower bounds of the computational region. computationalLBound must be allocated to be of size equal to the Grid dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the upper bounds of the computational region. computationalUBound must be allocated to be of size equal to the Grid dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the computational region per dimension. (i.e. computationalUBound-computationalLBound+1). computationalCount must be allocated to be of size equal to the Grid dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.32 ESMF_GridGet - Get information about a specific stagger location in a Grid

INTERFACE:

! Private name; call using ESMF_GridGet()
subroutine ESMF_GridGetPSloc(grid, staggerloc, &
distgrid, rc)

ARGUMENTS:

  type(ESMF_Grid), intent(in) :: grid
  type (ESMF_StaggerLoc), intent(in) :: staggerloc
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_DistGrid), intent(out), optional :: distgrid
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method gets information about a particular stagger location. This information is useful for creating an ESMF Array to hold the data at the stagger location.

The arguments are:
**grid** Grid to get the information from.

**staggerloc** The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations.

**[distgrid]** The structure describing the distribution of this staggerloc in this grid.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

30.6.33 ESMF_GridGet - Get information about a specific stagger location and tile in a Grid

**INTERFACE:**

```fortran
! Private name; call using ESMF_GridGet()
subroutine ESMF_GridGetPSlocPTile(grid, tile, staggerloc, &
  minIndex, maxIndex, rc)
```

**ARGUMENTS:**

- `type(ESMF_Grid), intent(in) :: grid`
- `integer, intent(in) :: tile`
- `type (ESMF_StaggerLoc), intent(in) :: staggerloc`
- `integer, target, intent(out), optional :: minIndex(:)`
- `integer, target, intent(out), optional :: maxIndex(:)`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

This method gets information about a particular stagger location. This information is useful for creating an ESMF Array to hold the data at the stagger location.

The arguments are:

- **grid** Grid to get the information from.
- **tile** The tile number to get the data from. Tile numbers range from 1 to TileCount.
- **staggerloc** The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations.
- **[minIndex]** Upon return this holds the global lower index of this stagger location. minIndex must be allocated to be of size equal to the grid DimCount. Note that this value is only for the first Grid tile, as multigrid support is added, this interface will likely be changed or moved to adapt.
Upon return this holds the global upper index of this stagger location. \texttt{maxIndex} must be allocated to be of size equal to the grid \texttt{DimCount}. Note that this value is only for the first Grid tile, as multigrid support is added, this interface will likely be changed or moved to adapt.

[**rc**] Return code; equals \texttt{ESMF_SUCCESS} if there are no errors.

### 30.6.34 ESMF\_GridGetCoord - Get a DE-local Fortran array pointer to Grid coord data and coord bounds

**INTERFACE:**

```fortran
subroutine ESMF_GridGetCoord<rank><type><kind>(grid, coordDim, &
    staggerloc, localDE, farrayPtr, datacopyflag, &
    exclusiveLBound, exclusiveUBound, exclusiveCount, &
    computationalLBound, computationalUBound, computationalCount, &
    totalLBound, totalUBound, totalCount, rc)
```

**ARGUMENTS:**

- `type(ESMF\_Grid), intent(in)` :: grid
- `integer, intent(in)` :: coordDim
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --`
- `type (ESMF\_StaggerLoc) intent(in), optional :: staggerloc`
- `integer, intent(in), optional :: localDE`
- `<type> (ESMF\_KIND_<kind>), pointer :: farrayPtr(<rank>)`
- `type(ESMF\_DataCopy\_Flag), intent(in), optional :: datacopyflag`
- `integer, intent(out), optional :: exclusiveLBound(:)`
- `integer, intent(out), optional :: exclusiveUBound(:)`
- `integer, intent(out), optional :: exclusiveCount(:)`
- `integer, intent(out), optional :: computationalLBound(:)`
- `integer, intent(out), optional :: computationalUBound(:)`
- `integer, intent(out), optional :: computationalCount(:)`
- `integer, intent(out), optional :: totalLBound(:)`
- `integer, intent(out), optional :: totalUBound(:)`
- `integer, intent(out), optional :: totalCount(:)`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

This method gets a Fortran pointer to the piece of memory which holds the coordinate data on the local DE for the given coordinate dimension and stagger locations. This is useful, for example, for setting the coordinate values in a Grid, or for reading the coordinate values. Currently this method supports up to three coordinate dimensions, of either R4 or R8 datatype. See below for specific supported values. If the coordinates that you are trying to retrieve are of
higher dimension, use the `ESMF_GetCoord()` interface that returns coordinate values in an `ESMF_Array` instead. That interface supports the retrieval of coordinates up to 7D.

Supported values for the `farrayPtr` argument are:

- `real(ESMF_KIND_R4), pointer :: farrayPtr(:)`
- `real(ESMF_KIND_R4), pointer :: farrayPtr(:,:)`
- `real(ESMF_KIND_R4), pointer :: farrayPtr(:,:,:)`
- `real(ESMF_KIND_R8), pointer :: farrayPtr(:)`
- `real(ESMF_KIND_R8), pointer :: farrayPtr(:,:)`
- `real(ESMF_KIND_R8), pointer :: farrayPtr(:,:,:)`

The arguments are:

- `grid` Grid to get the information from.
- `coordDim` The coordinate dimension to get the data from (e.g. 1=x).
- `[staggerloc]` The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to `ESMF_STAGGERLOC_CENTER`.
- `[localDE]` The local DE to get the information for. `[0,..,localDeCount-1]`
- `farrayPtr` The pointer to the coordinate data.
- `[datacopyflag]` If not specified, default to `ESMF_DATACOPY_REFERENCE`, in this case `farrayPtr` is a reference to the data in the Grid coordinate arrays. Please see Section 50.12 for further description and a list of valid values.
- `[exclusiveLBound]` Upon return this holds the lower bounds of the exclusive region. `exclusiveLBound` must be allocated to be of size equal to the `coord dimCount`.
- `[exclusiveUBound]` Upon return this holds the upper bounds of the exclusive region. `exclusiveUBound` must be allocated to be of size equal to the `coord dimCount`.
- `[exclusiveCount]` Upon return this holds the number of items, `exclusiveUBound-exclusiveLBound+1`, in the exclusive region per dimension. `exclusiveCount` must be allocated to be of size equal to the `coord dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- `[computationalLBound]` Upon return this holds the lower bounds of the stagger region. `computationalLBound` must be allocated to be of size equal to the `coord dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- `[computationalUBound]` Upon return this holds the upper bounds of the stagger region. `exclusiveUBound` must be allocated to be of size equal to the `coord dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- `[computationalCount]` Upon return this holds the number of items in the computational region per dimension (i.e. `computationalUBound-computationalLBound+1`). `computationalCount` must be allocated to be of size equal to the `coord dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- `[totalLBound]` Upon return this holds the lower bounds of the total region. `totalLBound` must be allocated to be of size equal to the `coord dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
Upon return this holds the upper bounds of the total region. `totalUBound` must be allocated to be of size equal to the coord `dimCount`. Please see Section [30.3.16](#) for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the total region per dimension (i.e. `totalUBound-totalLBound+1`). `totalCount` must be allocated to be of size equal to the coord `dimCount`. Please see Section [30.3.16](#) for a description of the regions and their associated bounds and counts.

Return code; equals `ESMF_SUCCESS` if there are no errors.

### 30.6.35 ESMF_GridGetCoord - Get coordinates and put into an Array

#### INTERFACE:

```fortran
! Private name; call using ESMF_GridGetCoord()
subroutine ESMF_GridGetCoordIntoArray(grid, coordDim, staggerloc, &
array, rc)
```

#### ARGUMENTS:

- `type(ESMF_Grid), intent(in) :: grid`
- `integer, intent(in) :: coordDim`
- `type (ESMF_StaggerLoc), intent(in), optional :: staggerloc`
- `type(ESMF_Array), intent(out) :: array`
- `integer, intent(out), optional :: rc`

#### STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

#### DESCRIPTION:

This method allows the user to get access to the ESMF Array holding coordinate data at a particular stagger location. This is useful, for example, to set the coordinate values. To have an Array to access, the coordinate Arrays must have already been allocated, for example by `ESMF_GridAddCoord` or `ESMF_GridSetCoord`.

The arguments are:

- `grid` The grid to get the coord array from.
- `coordDim` The coordinate dimension to get the data from (e.g. 1=x).
- `[staggerloc]` The stagger location from which to get the arrays. Please see Section [30.2.6](#) for a list of predefined stagger locations. If not present, defaults to `ESMF_STAGGERLOC_CENTER`.
- `array` An array into which to put the coordinate information.
- `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.
30.6.36 ESMF_GridGetCoord - Get DE-local coordinates from a specific index location in a Grid

INTERFACE:

! Private name; call using ESMF_GridGetCoord()
subroutine ESMF_GridGetCoordR4(grid, staggerloc, localDe, &
index, coord, rc)

ARGUMENTS:

  type(ESMF_Grid), intent(in) :: grid
  type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
  integer, intent(in), optional :: localDE
  integer, intent(in) :: index(:)
  real(ESMF_KIND_R4), intent(out) :: coord(:)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Given a specific index location in a Grid, this method returns the full set of coordinates from that index location. This method will eventually be overloaded to support the full complement of types supported by the Grid.

The arguments are:

[grid] Grid to get the information from.

[staggerloc] The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.

[localDE] The local DE to get the information for. [0,..,localDeCount-1]

[index] This array holds the index location to be queried in the Grid. This array must at least be of the size Grid rank.

[coord] This array will be filled with the coordinate data. This array must at least be of the size Grid rank.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.37 ESMF_GridGetCoord - Get DE-local coordinates from a specific index location in a Grid

INTERFACE:

! Private name; call using ESMF_GridGetCoord()
subroutine ESMF_GridGetCoordR8(grid, staggerloc, localDe, &
index, coord, rc)
ARGUMENTS:

```fortran
  type (ESMF_Grid), intent(in) :: grid
  type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
  integer, intent(in), optional :: localDE
  integer, intent(in) :: index(:)
  real(ESMF_KIND_R8), intent(out) :: coord(:,)

  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Given a specific index location in a Grid, this method returns the full set of coordinates from that index location. This method will eventually be overloaded to support the full complement of types supported by the Grid.

The arguments are:

**grid** Grid to get the information from.

**[staggerloc]** The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.

**[localDE]** The local DE to get the information for. [0,..,localDECount-1]

**index** This array holds the index location to be queried in the Grid. This array must at least be of the size Grid rank.

**coord** This array will be filled with the coordinate data. This array must at least be of the size Grid rank.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

30.6.38  ESMF_GridGetCoordBounds - Get Grid coordinate bounds

INTERFACE:

```fortran
  subroutine ESMF_GridGetCoordBounds (grid, coordDim, &
    staggerloc, localDE, exclusiveLBound, exclusiveUBound, &
    exclusiveCount, computationalLBound, computationalUBound, &
    computationalCount, totalLBound, totalUBound, totalCount, rc)
```

ARGUMENTS:

```fortran
  type (ESMF_Grid), intent(in) :: grid
  integer, intent(in) :: coordDim

  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
```
This method gets information about the range of index space which a particular piece of coordinate data occupies. In other words, this method returns the bounds of the coordinate arrays. Note that unlike the output from the Array, these values also include the undistributed dimensions and are ordered to reflect the order of the indices in the coordinate. So, for example, totalLBound and totalUBound should match the bounds of the Fortran array retrieved by ESMF/GridGetCoord.

The arguments are:

- **grid** Grid to get the information from.
- **coordDim** The coordinate dimension to get the information for (e.g. 1=x).
- **[staggerloc]** The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.
- **[localDE]** The local DE from which to get the information. [0,..,localDECount-1]
- **[exclusiveLBound]** Upon return this holds the lower bounds of the exclusive region. exclusiveLBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- **[exclusiveUBound]** Upon return this holds the upper bounds of the exclusive region. exclusiveUBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- **[exclusiveCount]** Upon return this holds the number of items, exclusiveUBound-exclusiveLBound+1, in the exclusive region per dimension. exclusiveCount must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- **[computationalLBound]** Upon return this holds the lower bounds of the stagger region. computationalLBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- **[computationalUBound]** Upon return this holds the upper bounds of the stagger region. computationalUBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
- **rc**
Upon return this holds the number of items in the computational region per dimension (i.e. computationalUBound-computationalLBound+1). computationalCount must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the total region. totalLBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the upper bounds of the total region. totalUBound must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the total region per dimension (i.e. totalUBound-totalLBound+1). totalCount must be allocated to be of size equal to the coord dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Return code; equals ESMF_SUCCESS if there are no errors.

30.6.39 ESMF_GridGetItem - Get a DE-local Fortran array pointer to Grid item data and item bounds

INTERFACE:

subroutine ESMF_GridGetItem<rank><type><kind>(grid, itemflag, & staggerloc, localDE, farrayPtr, datacopyflag, & exclusiveLBound, exclusiveUBound, exclusiveCount, & computationalLBound, computationalUBound, computationalCount, & totalLBound, totalUBound, totalCount, rc)

ARGUMENTS:

type(ESMF_Grid), intent(in) :: grid

type (ESMF_GridItem_Flag),intent(in) :: itemflag

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
integer, intent(in), optional :: localDE
<type> (ESMF_KIND_<kind>), pointer :: farrayPtr(<rank>)

type(ESMF_DataCopy_Flag),intent(in), optional :: datacopyflag
integer, intent(out), optional :: exclusiveLBound(:)
integer, intent(out), optional :: exclusiveUBound(:)
integer, intent(out), optional :: exclusiveCount(:)
integer, intent(out), optional :: computationalLBound(:)
integer, intent(out), optional :: computationalUBound(:)
integer, intent(out), optional :: computationalCount(:)
integer, intent(out), optional :: totalLBound(:)
integer, intent(out), optional :: totalUBound(:)
integer, intent(out), optional :: totalCount(:)
integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method gets a Fortran pointer to the piece of memory which holds the item data on the local DE for the given stagger locations. This is useful, for example, for setting the item values in a Grid, or for reading the item values. Currently this method supports up to three grid dimensions, but is limited to the I4 datatype. See below for specific supported values. If the item values that you are trying to retrieve are of higher dimension, use the ESMF_GetItem() interface that returns coordinate values in an ESMF_Array instead. That interface supports the retrieval of coordinates up to 7D.

Supported values for the farrayPtr argument are:

- integer(ESMF_KIND_I4), pointer :: farrayPtr(:)
- integer(ESMF_KIND_I4), pointer :: farrayPtr(:,:)
- integer(ESMF_KIND_I4), pointer :: farrayPtr(:,:,:)
- real(ESMF_KIND_R4), pointer :: farrayPtr(:)
- real(ESMF_KIND_R4), pointer :: farrayPtr(:,:)
- real(ESMF_KIND_R4), pointer :: farrayPtr(:,:,:)
- real(ESMF_KIND_R8), pointer :: farrayPtr(:)
- real(ESMF_KIND_R8), pointer :: farrayPtr(:,:)
- real(ESMF_KIND_R8), pointer :: farrayPtr(:,:,:)

The arguments are:

- grid  Grid to get the information from.
- itemflag  The item to get the information for. Please see Section 30.2.2 for a list of valid items.
- staggerloc  The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.
- localDE  The local DE to get the information for. [0,..,localDECount-1]
- farrayPtr  The pointer to the item data.
- datacopyflag  If not specified, default to ESMF_DATACOPY_REFERENCE, in this case farrayPtr is a reference to the data in the Grid item arrays. Please see Section 50.12 for further description and a list of valid values.
- exclusiveLBound  Upon return this holds the lower bounds of the exclusive region. exclusiveLBound must be allocated to be of size equal to the grid dimCount.
- exclusiveUBound  Upon return this holds the upper bounds of the exclusive region. exclusiveUBound must be allocated to be of size equal to the grid dimCount.
- exclusiveCount  Upon return this holds the number of items in the exclusive region per dimension (i.e. exclusiveUBound-exclusiveLBound+1). exclusiveCount must be allocated to be of size equal to the grid dimCount. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
Upon return this holds the lower bounds of the stagger region. `computationalLBound` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the upper bounds of the stagger region. `computationalUBound` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the computational region per dimension (i.e. `computationalUBound-computationalLBound+1`). `computationalCount` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the lower bounds of the total region. `totalLBound` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the upper bounds of the total region. `totalUBound` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Upon return this holds the number of items in the total region per dimension (i.e. `totalUBound-totalLBound+1`). `totalCount` must be allocated to be of size equal to the grid `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

Return code; equals `ESMF_SUCCESS` if there are no errors.

30.6.40  ESMF_GridGetItem - Get a Grid item and put into an Array

INTERFACE:

```fortran
! Private name; call using ESMF_GridGetItem()
subroutine ESMF_GridGetItemIntoArray(grid, itemflag, staggerloc, &
array, rc)
```

ARGUMENTS:

- `type (ESMF_Grid), intent (in) :: grid`
- `type (ESMF_GridItem_Flag), intent (in) :: itemflag`
- `type (ESMF_StaggerLoc), intent (in), optional :: staggerloc`
- `type (ESMF_Array), intent (out) :: array`
- `integer, intent (out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

This method allows the user to get access to the ESMF Array holding item data at a particular stagger location. This is useful, for example, to set the item values. To have an Array to access, the item Array must have already been allocated, for example by ESMF_GridAddItem or ESMF_GridSetItem.

The arguments are:

**grid**  Grid to get the information from.

**itemflag**  The item from which to get the arrays. Please see Section 30.2.2 for a list of valid items.

**[staggerloc]**  The stagger location from which to get the arrays. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.

**array**  An array into which to put the item information.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

30.6.41  ESMF_GridGetItemBounds - Get DE-local item bounds from a Grid

INTERFACE:

```
subroutine ESMF_GridGetItemBounds(grid, itemflag, 
  staggerloc, localDE, 
  exclusiveLBound, exclusiveUBound, exclusiveCount, 
  computationalLBound, computationalUBound, computationalCount, 
  totalLBound, totalUBound, totalCount, rc)
```

ARGUMENTS:

```
type(ESMF_Grid), intent(in) :: grid

type (ESMF_GridItem_Flag), intent(in) :: itemflag

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
integer, target, intent(out), optional :: localDE
integer, target, intent(out), optional :: exclusiveLBound(:)
integer, target, intent(out), optional :: exclusiveUBound(:)
integer, target, intent(out), optional :: exclusiveCount(:)
integer, target, intent(out), optional :: computationalLBound(:)
integer, target, intent(out), optional :: computationalUBound(:)
integer, target, intent(out), optional :: computationalCount(:)
integer, target, intent(out), optional :: totalLBound(:)
integer, target, intent(out), optional :: totalUBound(:)
integer, target, intent(out), optional :: totalCount(:)
integer, intent(out), optional :: rc
```

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method gets information about the range of index space which a particular piece of item data occupies. In other words, this method returns the bounds of the item arrays. Note that unlike the output from the Array, these values also include the undistributed dimensions and are ordered to reflect the order of the indices in the item. So, for example, `totalLBound` and `totalUBound` should match the bounds of the Fortran array retrieved by `ESMF_GridGetItem`.

The arguments are:

- **grid** Grid to get the information from.
- **itemflag** The item to get the information for. Please see Section 30.2.2 for a list of valid items.
- **[staggerloc]** The stagger location to get the information for. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to `ESMF_STAGGERLOC_CENTER`.
- **[localDE]** The local DE from which to get the information. `[0,...,localDeCount-1]`

- **[exclusiveLBound]** Upon return this holds the lower bounds of the exclusive region. `exclusiveLBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[exclusiveUBound]** Upon return this holds the upper bounds of the exclusive region. `exclusiveUBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[exclusiveCount]** Upon return this holds the number of items, `exclusiveCount = exclusiveUBound-exclusiveLBound+1`, in the exclusive region per dimension. `exclusiveCount` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[computationalLBound]** Upon return this holds the lower bounds of the stagger region. `computationalLBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[computationalUBound]** Upon return this holds the upper bounds of the stagger region. `computationalUBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[computationalCount]** Upon return this holds the number of items in the computational region per dimension (i.e. `computationalCount = computationalUBound-computationalLBound+1`). `computationalCount` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[totalLBound]** Upon return this holds the lower bounds of the total region. `totalLBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[totalUBound]** Upon return this holds the upper bounds of the total region. `totalUBound` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.

- **[totalCount]** Upon return this holds the number of items in the total region per dimension (i.e. `totalCount = totalUBound-totalLBound+1`). `totalCount` must be allocated to be of size equal to the item `dimCount`. Please see Section 30.3.16 for a description of the regions and their associated bounds and counts.
30.6.42 ESMF_GridMatch - Check if two Grid objects match

INTERFACE:

    function ESMF_GridMatch(grid1, grid2, rc)

RETURN VALUE:

    type(ESMF_GridMatch_Flag) :: ESMF_GridMatch

ARGUMENTS:

    type(ESMF_Grid), intent(in) :: grid1
    type(ESMF_Grid), intent(in) :: grid2
    integer, intent(out), optional :: rc

DESCRIPTION:

Check if grid1 and grid2 match. Returns a range of values of type ESMF_GridMatch indicating how closely the Grids match. For a description of the possible return values, please see 30.2.3. Please also note that this call returns the match for the piece of the Grids on the local PET only. It's entirely possible for this call to return a different match on different PETs for the same Grids. The user is responsible for computing the global match across the set of PETs.

The arguments are:

grid1 ESMF_Grid object.
grid2 ESMF_Grid object.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.6.43 ESMF_GridSetCoord - Set coordinates using Arrays

INTERFACE:

    subroutine ESMF_GridSetCoordFromArray(grid, coordDim, staggerloc, &
                                          array, rc)

ARGUMENTS:
type (ESMF_Grid), intent(in) :: grid
integer, intent(in) :: coordDim
type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
type (ESMF_Array), intent(in) :: array

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method sets the passed in Array as the holder of the coordinate data for stagger location staggerloc and coordinate coord. This method can be used in place of ESMF_GridAddCoord(). In fact, if the Grid location already contains an Array for this coordinate, then this one replaces it. For this method to replace ESMF_GridAddCoord() and produce a valid set of coordinates, then this method must be used to set an Array for each coordDim ranging from 1 to the dimCount of the passed in Grid.

The arguments are:

grid  The grid to set the coord in.
coordDim  The coordinate dimension to put the data in (e.g. 1=x).
[staggerloc]  The stagger location into which to copy the arrays. Please see Section 30.2.6 for a list of predefined stagger locations. If not present, defaults to ESMF_STAGGERLOC_CENTER.
array  An array to set the grid coordinate information from.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

30.6.44  ESMF_GridSetItem - Set an item using an Array

INTERFACE:

! Private name; call using ESMF_GridSetItem()
subroutine ESMF_GridSetItemFromArray(grid, itemflag, staggerloc, array, rc)

ARGUMENTS:

type (ESMF_Grid), intent(in) :: grid
type (ESMF_GridItem_Flag), intent(in) :: itemflag
type (ESMF_StaggerLoc), intent(in), optional :: staggerloc
type (ESMF_Array), intent(in) :: array

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method sets the passed in Array as the holder of the item data for stagger location \texttt{staggerloc} and item \texttt{itemflag}. If the location already contains an Array, then this one overwrites it. This method can be used as a replacement for \texttt{ESMF_GridAddItem()}.

The arguments are:

\texttt{grid} - The grid in which to set the array.

\texttt{itemflag} - The item into which to copy the arrays. Please see Section \ref{sec:griditems} for a list of valid items.

\texttt{[staggerloc]} - The stagger location into which to copy the arrays. Please see Section \ref{sec:staggerlocations} for a list of predefined stagger locations. If not present, defaults to \texttt{ESMF_STAGGERLOC\_CENTER}.

\texttt{array} - An array to set the grid item information from.

\texttt{[rc]} - Return code; equals \texttt{ESMF\_SUCCESS} if there are no errors.

30.6.45 \texttt{ESMF\_GridValidate} - Validate Grid internals

INTERFACE:

\begin{verbatim}
subroutine ESMF_GridValidate(grid, rc)

ARGUMENTS:

- type(ESMF\_Grid), intent(in) :: grid
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
- integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Validates that the \texttt{Grid} is internally consistent. Note that one of the checks that the Grid validate does is the Grid status. Currently, the validate will return an error if the grid is not at least \texttt{ESMF\_GRID\_STATUS\_COMPLETE}. This means that if a Grid was created with the \texttt{ESMF\_GridEmptyCreate} method, it must also have been finished with \texttt{ESMF\_GridEmptyComplete()} to be valid. If a Grid was created with another create call it should automatically have the correct status level to pass the status part of the validate. The Grid validate at this time doesn’t check for the presence or consistency of the Grid coordinates. The method returns an error code if problems are found.

The arguments are:
grid Specified ESMF_Grid object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

30.7 Class API: StaggerLoc Methods

30.7.1 ESMF_StaggerLocSet - Set a StaggerLoc to a particular position in the cell

INTERFACE:

! Private name; call using ESMF_StaggerLocSet()
subroutine ESMF_StaggerLocSetAllDim(staggerloc, loc, keyordenforcer, rc)

ARGUMENTS:

type (ESMF_StaggerLoc), intent(inout) :: staggerloc
integer, intent(in) :: loc(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets a custom staggerloc to a position in a cell by using the array loc. The values in the array should only be 0,1. If loc(i) is 0 it means the position should be in the center in that dimension. If loc(i) is 1 then for dimension i, the position should be on the side of the cell. Please see Section 30.3.22 for diagrams and further discussion of custom stagger locations.

The arguments are:

staggerloc Grid location to be initialized

loc Array holding position data. Each entry in loc should only be 0 or 1. note that dimensions beyond those specified are set to 0.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
30.7.2  ESMF_StaggerLocSet - Set one dimension of a StaggerLoc to a particular position

INTERFACE:

! Private name; call using ESMF_StaggerLocSet()
subroutine ESMF_StaggerLocSetDim(staggerloc, dim, loc, &
keywordenforcer, rc)

ARGUMENTS:

type (ESMF_StaggerLoc), intent(inout) :: staggerloc
integer, intent(in) :: dim
integer, intent(in) :: loc
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets a particular dimension of a custom staggerloc to a position in a cell by using the variable loc. The variable loc should only be 0,1. If loc is 0 it means the position should be in the center in that dimension. If loc is +1 then for the dimension, the position should be on the positive side of the cell. Please see Section 30.3.22 for diagrams and further discussion of custom stagger locations.

The arguments are:

staggerloc  Stagger location to be initialized

dim   Dimension to be changed (1-7).

loc   Position data should be either 0,1.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

30.7.3  ESMF_StaggerLocString - Return a StaggerLoc as a string

INTERFACE:

subroutine ESMF_StaggerLocString(staggerloc, string, keywordenforcer, &
rc)

ARGUMENTS:
type(ESMF_StaggerLoc), intent(in) :: staggerloc
character (len = *), intent(out) :: string
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, optional, intent(out) :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Return an ESMF_StaggerLoc as a printable string.
The arguments are:

staggerloc  The ESMF_StaggerLoc to be turned into a string.
string  Return string.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

30.7.4  ESMF_StaggerLocPrint - Print StaggerLoc information

INTERFACE:

subroutine ESMF_StaggerLocPrint(staggerloc, keywordenforcer, rc)

ARGUMENTS:

type (ESMF_StaggerLoc), intent(in) :: staggerloc
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, optional, intent(out) :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Print the internal data members of an ESMF_StaggerLoc object.
The arguments are:

staggerloc  ESMF_StaggerLoc object as the method input
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
31 LocStream Class

31.1 Description

A location stream (LocStream) is used to represent the locations of a set of data points. The values of the data points are stored within a Field or FieldBundle created using the LocStream.

In the data assimilation world, LocStreams can be thought of as a set of observations. Their locations are generally described using Cartesian (x, y, z), or (lat, lon, height) coordinates. There is no assumption of any regularity in the positions of the points. To make the concept more general, the locations for each data point are represented using a construct called keys. Keys can include other descriptors besides location, including a second set of coordinates.

Although keys are similar in concept to ESMF Attributes they have important differences. First, keys always occur as vectors, never as scalars. Second, keys are local to the DE: each DE can have a different key list with a different number of elements. Third, the local key list always has the same number of elements as there are local observations on that DE. Finally, keys may be used for the distribution of LocStreams. As such, they must be defined before the LocStream is distributed.

LocStreams can be very large. Data assimilation systems might use LocStreams with up to $10^8$ observations, so efficiency is critical.

Common operations involving LocStreams are similar to those involving Grids. In data assimilation, for example, there is an immediate need to:

1. Create a Field or FieldBundle on a LocStream
2. Redistribute data between Fields defined on LocStreams
3. Gather or scatter a FieldBundle defined on a LocStream from/to a root DE
4. Halo region exchange for a Field defined by a haloed LocStream
5. Extract Fortran array from Field which was defined by a LocStream

The operations on the Fortran arrays underlying LocStreams are usually simple numerical ones. However, it is necessary to sort them in place, and access only portions of the them. It would not be efficient to continually create new LocStreams to reflect this sorting. Instead, the sorting is managed by the application through permutation arrays while keeping the data in place. Locations can become inactive, e.g., if the quality control asserts that observation is invalid. This can be managed again by the application through masks.

A LocStream differs from a Grid in that no topological structure is maintained between the points (e.g. the class contains no information about which point is the neighbor of which other point).

A LocStream is similar to a Mesh in that both are collections of irregularly positioned points. However, the two structures differ because a Mesh also has connectivity: each data point has a set of neighboring data points. There is no requirement that the points in a LocStream have connectivity, in fact there is no requirement that any two points have any particular spatial relationship at all.

31.2 Use and Examples

31.2.1 Create a LocStream with user allocated memory

The following is an example of creating a LocStream object. After creation, key data is added, and a Field is created to hold data (temperature) at each location.
allocate(lon(numLocationsOnThisPet))
allocate(lat(numLocationsOnThisPet))

do i=1,numLocationsOnThisPet
  lon(i)=360.0/numLocationsOnThisPet
  lat(i)=0.0
enddo

allocate(temperature(numLocationsOnThisPet))

do i=1,numLocationsOnThisPet
  temperature(i)=90.0
enddo

locstream=ESMF_LocStreamCreate(name="Equatorial Measurements", &
                             localCount=numLocationsOnThisPet, &
                             rc=rc)

call ESMF_LocStreamAddKey(locstream, &
                          keyName="Lat", &
                          farray=lat, &
                          datacopyflag=ESMF_DATACOPY_REFERENCE, &
                          keyUnits="Degrees", &
                          keyLongName="Latitude", rc=rc)

call ESMF_LocStreamAddKey(locstream, &
                          keyName="Lon", &
                          farray=lon, &
                          datacopyflag=ESMF_DATACOPY_REFERENCE, &
                          keyUnits="Degrees", &
                          keyLongName="Longitude", rc=rc)
31.2.2 Create a LocStream with internally allocated memory

The following is an example of creating a LocStream object. After creation, key data is internally allocated, the pointer is retrieved, and the data is set. A Field is also created on the LocStream to hold data (temperature) at each location.

allocate(temperature(numLocationsOnThisPet))
do i=1,numLocationsOnThisPet
   temperature(i)=80.0
enddo

call ESMF_LocStreamAddKey(locstream, 
   keyName="Lat", &
   KeyTypeKind=ESMF_TYPEKIND_R8, &
   KeyUnits="Degrees", &
   keyLongName="Latitude", rc=rc)

call ESMF_LocStreamAddKey(locstream, 
   keyName="Lon", &
   KeyTypeKind=ESMF_TYPEKIND_R8, &
keyUnits="Degrees", &
keyLongName="Longitude", rc=rc)

!-------------------------------------------------- -----------------
! Get key data.
!-------------------------------------------------- -----------------
call ESMF_LocStreamGetKey(locstream, &
  localDE=0, &
  keyName="Lat", &
  farray=lat, &
  rc=rc)

call ESMF_LocStreamGetKey(locstream, &
  localDE=0, &
  keyName="Lon", &
  farray=lon, &
  rc=rc)

!-------------------------------------------------- -----------------
! Set key data.
!-------------------------------------------------- -----------------
do i=1,numLocationsOnThisPet
  lon(i)=360.0/numLocationsOnThisPet
  lat(i)=0.0
endo

!-------------------------------------------------- -----------------
! Create a Field on the Location Stream. In this case the
! Field is created from a user array, but any of the other
! Field create methods (e.g. from ArraySpec) would also apply.
!-------------------------------------------------- -----------------
field_temperature=ESMF_FieldCreate(locstream, &
  temperature, &
  name="temperature", &
  rc=rc)

31.2.3 Create a LocStream from a background Grid

The following is an example of creating a LocStream object from another LocStream object using a background Grid. The new LocStream contains the data present in the old LocStream, but is redistributed so that entries with a given set of coordinates are on the same PET as the piece of the background Grid which contains those coordinates.
! Create the LocStream: Allocate space for the LocStream object, 
! define the number and distribution of the locations.

locstream=ESMF_LocStreamCreate(name="Equatorial Measurements", &
    localCount=numLocationsOnThisPet, &
    rc=rc)

! Add key data (internally allocating memory).

call ESMF_LocStreamAddKey(locstream, &
    keyName="Lon", &
    KeyTypeKind=ESMF_TYPEKIND_R8, &
    keyUnits="Degrees", &
    keyLongName="Longitude", rc=rc)

call ESMF_LocStreamAddKey(locstream, &
    keyName="Lat", &
    KeyTypeKind=ESMF_TYPEKIND_R8, &
    keyUnits="Degrees", &
    keyLongName="Latitude", rc=rc)

! Get Fortran arrays which hold the key data, so that it can be set. 
! Using localDE=0, because the locstream was created with 1 DE per PET.

!*************************************************************************

call ESMF_LocStreamGetKey(locstream, &
    localDE=0, &
    keyName="Lon", &
    farray=lon, &
    rc=rc)

call ESMF_LocStreamGetKey(locstream, &
    localDE=0, &
    keyName="Lat", &
    farray=lat, &
    rc=rc)
! Set the longitude and latitude coordinates of the points in the ! LocStream. Each PET contains points scattered around the equator.

do i=1,numLocationsOnThisPet
  lon(i)=0.5+REAL(i-1)*360.0/numLocationsOnThisPet
  lat(i)=0.0
enddo

! Create a Grid to use as the background. The Grid is ! GridLonSize by GridLatSize with the default distribution ! (The first dimension split across the PETs). The coordinate range ! is 0 to 360 in longitude and -90 to 90 in latitude. Note that we ! use indexflag=ESMF_INDEX_GLOBAL for the Grid creation. At this time ! this is required for a Grid to be usable as a background Grid. ! Note that here the points are treated as cartesian.

grid=ESMF_GridCreateNoPeriDim(maxIndex=(/GridLonSize,GridLatSize/), &
  coordSys=ESMF_COORDSYS_CART, &
  indexflag=ESMF_INDEX_GLOBAL, &
  rc=rc)

! Allocate the corner stagger location in which to put the coordinates. ! (The corner stagger must be used for the Grid to be usable as a ! background Grid.)

call ESMF_GridAddCoord(grid, staggerloc=ESMF_STAGGERLOC_CORNER, rc=rc)

! Get access to the Fortran array pointers that hold the Grid ! coordinate information and then set the coordinates to be uniformly ! distributed around the globe.

call ESMF_GridGetCoord(grid, localDE=0, &
  staggerLoc=ESMF_STAGGERLOC_CORNER, &
  coordDim=1, computationalLBound=clbnd, &
  computationalUBound=cubnd, &
  farrayPtr=farrayPtrLonC, rc=rc)

call ESMF_GridGetCoord(grid, localDE=0, &
  staggerLoc=ESMF_STAGGERLOC_CORNER, &
  coordDim=2, farrayPtr=farrayPtrLatC, rc=rc)
do i1=clbnd(1),cubnd(1)
do i2=clbnd(2),cubnd(2)
    ! Set Grid longitude coordinates as 0 to 360
    farrayPtrLonC(i1,i2) = REAL(i1-1) * 360.0/REAL(GridLonSize)

    ! Set Grid latitude coordinates as -90 to 90
    farrayPtrLatC(i1,i2) = -90. + REAL(i2-1) * 180.0/REAL(GridLatSize) + &
                           0.5*180.0/REAL(GridLatSize)
enddo
endo

!-------------------------------------------------- -----------------
! Create newLocstream on the background Grid using the
! "Lon" and "Lat" keys as the coordinates for the entries in
! locstream. The entries in newLocstream with coordinates (lon,lat)
! are on the same PET as the piece of grid which contains (lon,lat).
!-------------------------------------------------- -----------------
newLocstream=ESMF_LocStreamCreate(locstream, coordKeyNames="Lon:Lat", &
background=grid, rc=rc)

!-------------------------------------------------- -----------------
! A Field can now be created on newLocstream and
! ESMF_FieldRedist() can be used to move data between Fields built
! on locstream and Fields built on newLocstream.
!-------------------------------------------------- -----------------

31.3 Class API

31.3.1 ESMF_LocStreamAssignment(=) - LocStream assignment

INTERFACE:

    interface assignment(=)
    locstream1 = locstream2

ARGUMENTS:

    type(ESMF_LocStream) :: locstream1
    type(ESMF_LocStream) :: locstream2

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface com-
piles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Assign locstream1 as an alias to the same ESMF LocStream object in memory as locstream2. If locstream2 is invalid, then locstream1 will be equally invalid after the assignment.

The arguments are:

**locstream1** The ESMF_LocStream object on the left hand side of the assignment.

**locstream2** The ESMF_LocStream object on the right hand side of the assignment.

### 31.3.2 ESMF_LocStreamOperator(==) - LocStream equality operator

**INTERFACE:**

```plaintext
interface operator(==)
  if (locstream1 == locstream2) then ... endif
  OR
  result = (locstream1 == locstream2)
end interface
```

**RETURN VALUE:**

```
logical :: result
```

**ARGUMENTS:**

```
type(ESMF_LocStream), intent(in) :: locstream1
type(ESMF_LocStream), intent(in) :: locstream2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Test whether locstream1 and locstream2 are valid aliases to the same ESMF LocStream object in memory. For a more general comparison of two ESMF LocStreams, going beyond the simple alias test, the ESMF_LocStreamMatch() function (not yet implemented) must be used.

The arguments are:

**locstream1** The ESMF_LocStream object on the left hand side of the equality operation.

**locstream2** The ESMF_LocStream object on the right hand side of the equality operation.
31.3.3  ESMF_LocStreamOperator(/=) - LocStream not equal operator

INTERFACE:

```plaintext
interface operator(/=)
    if (locstream1 /= locstream2) then ... endif
OR
    result = (locstream1 /= locstream2)
end interface
```

RETURN VALUE:

```
logical :: result
```

ARGUMENTS:

```
type(ESMF_LocStream), intent(in) :: locstream1
type(ESMF_LocStream), intent(in) :: locstream2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether locstream1 and locstream2 are not valid aliases to the same ESMF LocStream object in memory. For a more general comparison of two ESMF LocStreams, going beyond the simple alias test, the ESMF_LocStreamMatch() function (not yet implemented) must be used.

The arguments are:

- **locstream1** The ESMF_LocStream object on the left hand side of the non-equality operation.
- **locstream2** The ESMF_LocStream object on the right hand side of the non-equality operation.

31.3.4  ESMF_LocStreamAddKey - Add a key Array and allocate the internal memory

INTERFACE:

```plaintext
! Private name; call using ESMF_LocStreamAddKey()
subroutine ESMF_LocStreamAddKeyAlloc(locstream, keyName, keyTypeKind, &
    keyUnits, keyLongName, rc)
```

ARGUMENTS:
DESCRIPTION:

Add a key to a locstream. Once a key has been added its internal data can be retrieved and used to set key values.

The arguments are:

locstream  The ESMF_LocStream object to add key to.

keyName  The name of the key to add.

[keyTypeKind]  The type/kind of the key data. If not specified then the type/kind will default to 8 byte reals.

[keyUnits]  The units of the key data. If not specified, then the item remains blank.

[keyLongName]  The long name of the key data. If not specified, then the item remains blank.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

31.3.5 ESMF_LocStreamAddKey - Add a key Array

INTERFACE:

! Private name; call using ESMF_LocStreamAddKey()
subroutine ESMF_LocStreamAddKeyArray(locstream, keyName, keyArray, &
destroyKey, keyUnits, keyLongName, rc)

ARGUMENTS:

  type (ESMF_Locstream), intent(in) :: locstream
  character (len=*), intent(in) :: keyName
  type (ESMF_Array), intent(in) :: keyArray
  logical, intent(in), optional :: destroyKey
  character (len=*), intent(in), optional :: keyUnits
  character (len=*), intent(in), optional :: keyLongName
  integer, intent(out), optional :: rc

DESCRIPTION:

Add a key to a locstream. Once a key has been added its internal data can be retrieved and used to set key values.

The arguments are:

locstream  The ESMF_LocStream object to add key to.
**keyName**  The name of the key to add.

**keyArray**  An ESMF Array which contains the key data

[**destroyKey**] if .true. destroy this key array when the locstream is destroyed. Defaults to .false.

[**keyUnits**]  The units of the key data. If not specified, then the item remains blank.

[**keyLongName**]  The long name of the key data. If not specified, then the item remains blank.

[**rc**]  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 31.3.6 ESMF_LocStreamAddKey - Add a key Array created around user memory

**INTERFACE:**

```fortran
! Private name; call using ESMF_LocStreamAddKey()
subroutine ESMF_LocStreamAddKeyI4(locstream, keyName, farray, &
datacopyflag, keyUnits, keyLongName, rc)
```

**ARGUMENTS:**

- `type(ESMF_Locstream), intent(in) :: locstream`
- `character (len=*) , intent(in) :: keyName`
- `<farray> type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag`
- `character (len=*) , intent(in), optional :: keyUnits`
- `character (len=*) , intent(in), optional :: keyLongName`
- `integer, intent(out), optional :: rc`

**DESCRIPTION:**

Add a key to a locstream. Once a key has been added its internal data can be retrieved and used to set key values.

Supported values for `<farray>` are:

- `integer(ESMF_KIND_I4), intent(in) :: farray()`
- `real(ESMF_KIND_R4), intent(in) :: farray()`
- `real(ESMF_KIND_R8), intent(in) :: farray()`

The arguments are:

- `locstream`  The ESMF_LocStream object to add key to.
- `keyName`  The name of the key to add.
- `farray`  Valid native Fortran array, i.e. memory must be associated with the actual argument. The type/kind/rank information of `farray` will be used to set the key Array’s properties accordingly.
[datacopyflag] Specifies whether the Array object will reference the memory allocation provided by farray directly or will copy the data from farray into a new memory allocation. Valid options are ESMF_DATACOPY_REFERENCE (default) or ESMF_DATACOPY_VALUE. Depending on the specific situation the ESMF_DATACOPY_REFERENCE option may be unsafe when specifying an array slice for farray.

[keyUnits] The units of the key data. If not specified, then the item remains blank.

[keyLongName] The long name of the key data. If not specified, then the item remains blank.

[rC] Return code; equals ESMF_SUCCESS if there are no errors.

31.3.7 ESMF_LocStreamCreate - Create a new LocStream by projecting onto a Grid

INTERFACE:

! Private name; call using ESMF_LocStreamCreate()
function ESMF_LocStreamCreateByBkgGrid(locstream, name, &
coordKeyNames, background, maskValues, &
unmappedaction, rc)

RETURN VALUE:

    type(ESMF_LocStream) :: ESMF_LocStreamCreateByBkgGrid

ARGUMENTS:

    type(ESMF_LocStream), intent(in) :: locstream
    character (len=*) , intent(in), optional :: name
    character (len=*) , intent(in) :: coordKeyNames
    type(ESMF_Grid), intent(in) :: background
    integer(ESMF_KIND_I4), intent(in), optional :: maskValues(:)
    type(ESMF_UnmappedAction_Flag), intent(in), optional :: unmappedaction
    integer, intent(out), optional :: rc

DESCRIPTION:

Create an location stream from an existing one in accordance with the distribution of the background Grid. The entries in the new location stream are redistributed, so that they lie on the same PET as the piece of Grid which contains the coordinates of the entries. The coordinates of the entries are the data in the keys named by coordKeyNames. To copy data in Fields or FieldBundles built on locstream to the new one simply use ESMF_FieldRedist() or ESMF_FieldBundleRedist().

The arguments are:

locstream Location stream from which the new location stream is to be created

[name] Name of the resulting location stream
coordKeyNames  Names of the keys used to determine the link to background Grid. The first key in this list matches up with the first coordinate of the Grid, the second key in this list matches up with the second coordinate of the Grid, and so on. The key names should be separated by the : character.

background  Background Grid which determines the distribution of the entries in the new location stream. The background Grid needs to have the same number of dimensions as the number of keys in coordKeyNames. Note also that this subroutine uses the corner stagger location in the Grid for determining where a point lies, because this is the stagger location which fully contains the cell. A Grid must have coordinate data in this stagger location to be used in this subroutine. For a 2D Grid this stagger location is ESMF_STAGGERLOC_CORNER for a 3D Grid this stagger location is ESMF_STAGGERLOC_CORNER_VFACE. Note that currently the background Grid also needs to have been created with indexflag=ESMF_INDEX_GLOBAL to be usable here.

[maskValues]  List of values that indicate a background grid point should be masked out. If not specified, no masking will occur.

[unmappedaction]  Specifies what should happen if there are destination points that can’t be mapped to a source cell. Options are ESMF_UNMAPPEDACTION_ERROR or ESMF_UNMAPPEDACTION_IGNORE [NOT IMPLEMENTED]. If not specified, defaults to ESMF_UNMAPPEDACTION_ERROR.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

31.3.8  ESMF_LocStreamCreate - Create a new LocStream by projecting onto a Mesh

INTERFACE:

    ! Private name; call using ESMF_LocStreamCreate()
    function ESMF_LocStreamCreateByBkgMesh(locstream, name, &
        coordKeyNames, background, unmappedaction, rc)

RETURN VALUE:

    type(ESMF_LocStream) :: ESMF_LocStreamCreateByBkgMesh

ARGUMENTS:

    type(ESMF_LocStream), intent(in) :: locstream
    character (len=*) , intent(in), optional :: name
    character (len=*) , intent(in) :: coordKeyNames
    type(ESMF_Mesh), intent(in) :: background
    type(ESMF_UnmappedAction_Flag), intent(in), optional :: unmappedaction
    integer, intent(out),optional :: rc

DESCRIPTION:

Create an location stream from an existing one in accordance with the distribution of the background Mesh. The entries in the new location stream are redistributed, so that they lie on the same PET as the piece of Mesh which contains the coordinates of the entries. The coordinates of the entries are the data in the keys named by coordKeyNames. To copy data in Fields or FieldBundles built on locstream to the new one simply use ESMF_FieldRedist() or ESMF_FieldBundleRedist().

The arguments are:
**locstream** Location stream from which the new location stream is to be created

**[name]** Name of the resulting location stream

**coordKeyNames** Names of the keys used to determine the link to background Mesh. The first key in this list matches up with the first coordinate of the Mesh, the second key in this list matches up with the second coordinate of the Mesh, and so on. The key names should be separated by the ': ' character.

**background** Background Mesh which determines the distribution of entries in the new location stream. The Mesh must have the same spatial dimension as the number of keys in coordKeyNames.

**[unmappedaction]** Specifies what should happen if there are destination points that can’t be mapped to a source cell. Options are `ESMF_UNMAPPDEDATION_ERROR` or `ESMF_UNMAPPDEDATION_IGNORE` [NOT IMPLEMENTED]. If not specified, defaults to `ESMF_UNMAPPDEDATION_ERROR`.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

---

### 31.3.9 ESMF_LocStreamCreate - Create a new LocStream from a distgrid

**INTERFACE:**

```fortran
! Private name: call using ESMF_LocStreamCreate()
function ESMF_LocStreamCreateFromDG(name, distgrid, &
  destroyDistgrid, indexflag, rc )
```

**RETURN VALUE:**

```fortran
type(ESMF_LocStream) :: ESMF_LocStreamCreateFromDG
```

**ARGUMENTS:**

```fortran
character (len=*) , intent(in), optional :: name
    type(ESMF_DistGrid), intent(in) :: distgrid
logical, intent(in), optional :: destroyDistgrid
    type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Allocates memory for a new `ESMF_LocStream` object, constructs its internal derived types. The arguments are:

**name** Name of the location stream

**distgrid** Distgrid specifying size and distribution. Only 1D distgrids are allowed.

**[destroyDistgrid]** If .true. the locstream is responsible for destroying the distgrid. Defaults to .false.

**[indexflag]** Flag that indicates how the DE-local indices are to be defined. Defaults to `ESMF_INDEX_DELOCAL`, which indicates that the index range on each DE starts at 1. See Section S0.25 for the full range of options.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.
31.3.10  ESMF_LocStreamCreate - Create a new LocStream from an irregular distribution

INTERFACE:

    ! Private name: call using ESMF_LocStreamCreate()
    function ESMF_LocStreamCreateIrreg(name, minIndex, countsPerDE, &
        indexflag, rc)

RETURN VALUE:

type(ESMF_LocStream) :: ESMF_LocStreamCreateIrreg

ARGUMENTS:

    character (len=*) , intent(in) , optional                  :: name
    integer , intent(in) , optional                           :: minIndex
    integer , intent(in)                                     :: countsPerDE(:)
    type(ESMF_Index_Flag) , intent(in), optional             :: indexflag
    integer , intent(out) , optional                         :: rc

DESCRIPTION:

Allocates memory for a new ESMF_LocStream object, constructs its internal derived types. The ESMF_DistGrid is set up, indicating how the LocStream is distributed.

The arguments are:

name    Name of the location stream

[minIndex]  Number to start the index ranges at. If not present, defaults to 1.

countsPerDE  This array specifies the number of locations per DE.

[indexflag]  Flag that indicates how the DE-local indices are to be defined. Defaults to ESMF_INDEX_DELOCAL, which indicates that the index range on each DE starts at 1. See Section 50.25 for the full range of options.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

31.3.11  ESMF_LocStreamCreate - Create a new LocStream from a local count

INTERFACE:

    ! Private name: call using ESMF_LocStreamCreate()
    function ESMF_LocStreamCreateFromLocal(name, localCount, indexflag, rc)

RETURN VALUE:
type(ESMF_LocStream) :: ESMF_LocStreamCreateFromLocal

ARGUMENTS:

character (len=*), intent(in), optional :: name
integer, intent(in) :: localCount
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(out), optional :: rc

DESCRIPTION:

Allocates memory for a new ESMF_LocStream object, constructs its internal derived types. The ESMF_DistGrid is set up, indicating how the LocStream is distributed.

The arguments are:

name Name of the location stream
localCount Number of grid cells to be distributed to this DE.

[indexflag] Flag that indicates how the DE-local indices are to be defined. Defaults to ESMF_INDEX_DELOCAL, which indicates that the index range on each DE starts at 1. See Section 50.25 for the full range of options.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

31.3.12 ESMF_LocStreamCreate - Create a new LocStream using a regular distribution

INTERFACE:

! Private name: call using ESMF_LocStreamCreate()
function ESMF_LocStreamCreateReg(name, &
   regDecomp, decompFlag, minIndex, maxIndex, indexflag, rc )

RETURN VALUE:

type(ESMF_LocStream) :: ESMF_LocStreamCreateReg

ARGUMENTS:

character (len=*), intent(in), optional :: name
integer, intent(in), optional :: regDecomp
type(ESMF_Decomp_Flag), intent(in), optional :: decompflag
integer, intent(in), optional :: minIndex
integer, intent(in) :: maxIndex
type(ESMF_Index_Flag), intent(in), optional :: indexflag
integer, intent(out), optional :: rc
DESCRIPTION:

Allocates memory for a new ESMF_LocStream object, constructs its internal derived types. The ESMF_DistGrid is set up, indicating how the LocStream is distributed, at a later time.

The arguments are:

**name**  Name of the location stream

[regDecomp] Specify into how many chunks to divide the locations. If not specified, defaults to the number of PETs.

[decompFlag] Specify what to do with leftover locations after division. If not specified, defaults to ESMF_DECOMP_BALANCED. Please see Section 50.13 for a full description of the possible options.

[[minIndex]] The minimum index across all PETs. If not set defaults to 1.

maxIndex  The maximum index across all PETs.

[indexflag] Flag that indicates how the DE-local indices are to be defined. Defaults to ESMF_INDEX_DELOCAL, which indicates that the index range on each DE starts at 1. See Section 50.25 for the full range of options.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

---

31.3.13  ESMF_LocStreamDestroy - Release resources associated with a LocStream

INTERFACE:

```fortran
subroutine ESMF_LocStreamDestroy(locstream, keywordenforcer, rc)
```

ARGUMENTS:

```fortran
type(ESMF_LocStream), intent(inout) :: locstream
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Deallocate an ESMF_LocStream object and appropriate internal structures.

The arguments are:

locstream  locstream to destroy

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
31.3.14  ESMF_LocStreamGet - Return object-wide information from a LocStream

INTERFACE:

! Private name; call using ESMF_LocStreamGet()
subroutine ESMF_LocStreamGetDefault(locstream, distgrid, keyCount, &
   keyNames, localDECount, indexflag, name, rc)

ARGUMENTS:

type(ESMF_Locstream), intent(in)            :: locstream
 type(ESMF_DistGrid), intent(out), optional :: distgrid
 integer, intent(out),optional              :: keyCount
 character(len=ESMF_MAXSTR),optional        :: keyNames(:)
 integer, intent(out),optional              :: localDECount
 type(ESMF_Index_Flag), intent(out), optional :: indexflag
 character(len= * ), intent(out), optional   :: name
 integer, intent(out), optional             :: rc

DESCRIPTION:

Query an ESMF_LocStream for various information. All arguments after the locstream are optional.

The arguments are:

locstream    The ESMF_LocStream object to query.
[distgrid]   The ESMF_DistGrid object that describes
[keyCount]   Number of keys in the locstream.
[keyNames]   The names of the keys in the locstream. Keynames should be an array of character strings. The character strings should be of length ESMF_MAXSTR and the array’s length should be at least keyCount.
[localDECount] Number of DEs on this PET in the locstream.
[indexflag] The indexflag for this indexflag.
[name]      Name of queried item.
[rc]        Return code; equals ESMF_SUCCESS if there are no errors.

31.3.15  ESMF_LocStreamGetKey - Get an Array associated with a key

INTERFACE:

! Private name; call using ESMF_LocStreamGetKey()
subroutine ESMF_LocStreamGetKeyArray(locstream, keyName, keyArray, rc)

ARGUMENTS:
type (ESMF_Locstream), intent (in) :: locstream
character (len=*), intent (in) :: keyName
type (ESMF_Array), intent (out) :: keyArray
integer, intent (out), optional :: rc

DESCRIPTION:

Get ESMF Array associated with key.
The arguments are:

locstream  The ESMF_LocStream object to get key from.
keyName  The name of the key to get.
keyArray  Array associated with key.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

31.3.16  ESMF_LocStreamGetKey - Get the bounds of a key Array

INTERFACE:

! Private name; call using ESMF_LocStreamGetKey()
subroutine ESMF_LocStreamGetKeyBounds (locstream, localDE, keyName, &
exclusiveLBound, exclusiveUBound, exclusiveCount, &
computationalLBound, computationalUBound, computationalCount, &
totalLBound, totalUBound, totalCount, &
rc)

ARGUMENTS:

type (ESMF_LocStream), intent (in) :: locstream
integer, intent (in) :: localDE
character (len=*), intent (in) :: keyName
integer, intent (out), optional :: exclusiveLBound
integer, intent (out), optional :: exclusiveUBound
integer, intent (out), optional :: exclusiveCount
integer, intent (out), optional :: computationalLBound
integer, intent (out), optional :: computationalUBound
integer, intent (out), optional :: computationalCount
integer, intent (out), optional :: totalLBound
integer, intent (out), optional :: totalUBound
integer, intent (out), optional :: totalCount
integer, intent (out), optional :: rc

DESCRIPTION:

This method gets the bounds of a localDE for a locstream.
The arguments are:
locstream  LocStream to get the information from.

localDE  The local DE to get the information for. \([0, \ldots, \text{localDeCount}-1]\)

[exclusiveLBound]  Upon return this holds the lower bounds of the exclusive region.

[exclusiveUBound]  Upon return this holds the upper bounds of the exclusive region.

[exclusiveCount]  Upon return this holds the number of items in the exclusive region
(i.e. exclusiveUBound-exclusiveLBound+1).

[computationalLBound]  Upon return this holds the lower bounds of the computational region.

[computationalUBound]  Upon return this holds the upper bounds of the computational region.

[computationalCount]  Upon return this holds the number of items in the computational region
(i.e. computationalUBound-computationalLBound+1).

[totalLBound]  Upon return this holds the lower bounds of the total region.

[totalUBound]  Upon return this holds the upper bounds of the total region.

[totalCount]  Upon return this holds the number of items in the total region (i.e. totalUBound-totalLBound+1).

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

31.3.17  ESMF_LocStreamGetKey - Get info associated with a key

INTERFACE:

! Private name; call using ESMF_LocStreamGetKey()
subroutine ESMF_LocStreamGetKeyInfo(locstream, keyName, keyUnits, &
  keyLongName, typekind, rc)

ARGUMENTS:

  type(ESMF_Locstream), intent(in) :: locstream
  character (len=*) , intent(in) :: keyName
  character (len=*) , intent(out), optional :: keyUnits
  character (len=*) , intent(out), optional :: keyLongName
  type(ESMF_TypeKind_Flag), intent(out), optional :: typekind
  integer, intent(out), optional :: rc

DESCRIPTION:

Get ESMF Array associated with key.

The arguments are:

locstream  The ESMF_LocStream object to get key from.

keyName  The name of the key to get.
[keyUnits] The units of the key data. If not specified, then the item remains blank.

[keyLongName] The long name of the key data. If not specified, then the item remains blank.

[typekind] The typekind of the key data

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

31.3.18 ESMF_LocStreamGetKey - Get a DE-local Fortran array pointer to key values

INTERFACE:

! Private name; call using ESMF_LocStreamGetKey()
subroutine ESMF_LocStreamGetKeyI4(locstream, localDE, keyName, &
exclusiveLBound, exclusiveUBound, exclusiveCount, &
computationalLBound, computationalUBound, computationalCount, &
totalLBound, totalUBound, totalCount, &
farray, datacopyflag, rc)

ARGUMENTS:

type(ESMF_LocStream), intent(in) :: locstream
integer, intent(in) :: localDE
character (len=*) , intent(in) :: keyName
integer, intent(out), optional :: exclusiveLBound
integer, intent(out), optional :: exclusiveUBound
integer, intent(out), optional :: exclusiveCount
integer, intent(out), optional :: computationalLBound
integer, intent(out), optional :: computationalUBound
integer, intent(out), optional :: computationalCount
integer, intent(out), optional :: totalLBound
integer, intent(out), optional :: totalUBound
integer, intent(out), optional :: totalCount
<farray>
type(ESMF_DataCopy_Flag), intent(in), optional :: datacopyflag
integer, intent(out), optional :: rc

DESCRIPTION:

This method gets a Fortran pointer to the piece of memory which holds the key data for a particular key on the given local DE. This is useful, for example, for setting the key values in a LocStream, or for reading the values.

Supported values for <farray> are:

integer(ESMF_KIND_I4), pointer :: farray(:)
real(ESMF_KIND_R4), pointer :: farray(:)
real(ESMF_KIND_R8), pointer :: farray(:)

The arguments are:
locstream  LocStream to get the information from.
localDE   The local DE to get the information for. [0,..,localDeCount-1]
keyName   The key to get the information from.
[exclusiveLBound] Upon return this holds the lower bounds of the exclusive region.
[exclusiveUBound] Upon return this holds the upper bounds of the exclusive region.
[exclusiveCount] Upon return this holds the number of items in the exclusive region
               (i.e. exclusiveUBound-exclusiveLBound+1).exclusiveCount.
[computationalLBound] Upon return this holds the lower bounds of the computational region.
[computationalUBound] Upon return this holds the upper bounds of the computational region.
[computationalCount] Upon return this holds the number of items in the computational region
                      (i.e. computationalUBound-computationalLBound+1).
[totalLBound]       Upon return this holds the lower bounds of the total region.
[totalUBound]       Upon return this holds the upper bounds of the total region.
[totalCount]        Upon return this holds the number of items in the total region (i.e.
                     totalUBound-totalLBound+1).
farray   The pointer to the coordinate data.
[datacopyflag] If not specified, default to ESMF_DATACOPY_REFERENCE, in this case farray is a reference to the
           data in the Grid coordinate arrays. Please see Section 50.12 for further description and a list of valid values.
[rc]      Return code; equals ESMF_SUCCESS if there are no errors.

31.3.19   ESMF_LocStreamGet - Get DE-local bounds of a LocStream

INTERFACE:

    ! Private name; call using ESMF_LocStreamGet()
    subroutine ESMF_LocStreamGetBounds(locstream, localDE, &
        exclusiveLBound, exclusiveUBound, exclusiveCount, &
        computationalLBound, computationalUBound, computationalCount, &
        rc)

ARGUMENTS:

type(ESMF_LocStream),   intent(in) :: locstream
integer,               intent(in) :: localDE
integer,               intent(out), optional :: exclusiveLBound
integer,               intent(out), optional :: exclusiveUBound
integer,               intent(out), optional :: exclusiveCount
integer,               intent(out), optional :: computationalLBound
integer,               intent(out), optional :: computationalUBound
integer,               intent(out), optional :: computationalCount
integer, intent(out),  optional :: rc
DESCRIPTION:

This method gets the bounds of a localDE for a locstream.
The arguments are:

locstream LocStream to get the information from.
localDE The local DE to get the information for. [0,..,localDeCount-1]
[exclusiveLBound] Upon return this holds the lower bounds of the exclusive region.
[exclusiveUBound] Upon return this holds the upper bounds of the exclusive region.
[exclusiveCount] Upon return this holds the number of items in the exclusive region
(i.e. exclusiveUBound-exclusiveLBound+1). exclusiveCount.
[computationalLBound] Upon return this holds the lower bounds of the computational region.
[computationalUBound] Upon return this holds the upper bounds of the computational region.
[computationalCount] Upon return this holds the number of items in the computational region
(i.e. computationalUBound-computationalLBound+1). computationalCount.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

31.3.20 ESMF_LocStreamPrint - Print the contents of a LocStream

INTERFACE:

subroutine ESMF_LocStreamPrint(locstream, options, rc)

ARGUMENTS:

type(ESMF_LocStream), intent(inout) :: locstream
character (len = *), intent(in), optional :: options
integer, intent(out), optional :: rc

DESCRIPTION:

Prints information about the locstream to stdout. This subroutine goes through the internal data members of a
locstream data type and prints information of each data member.
The arguments are:

locstream
[options] Print options are not yet supported.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.
31.3.21  ESMF_LocStreamValidate - Check validity of a LocStream

INTERFACE:

    subroutine ESMF_LocStreamValidate(locstream, options, rc)

ARGUMENTS:

    type(ESMF_LocStream), intent(inout) :: locstream
    character (len = *), intent(in), optional :: options
    integer, intent(out), optional :: rc

DESCRIPTION:

Validates that the locstream is internally consistent. Currently this method determines if the locstream is uninitialized or already destroyed.

The method returns an error code if problems are found.

The arguments are:

locstream  ESMF_LocStream to validate.
[options]  Validation options are not yet supported.
[rc]  Return code; equals ESMF_SUCCESS if the locstream is valid.

32  Mesh Class

32.1  Description

Unstructured grids are commonly used in the computational solution of partial differential equations. These are especially useful for problems that involve complex geometry, where using the less flexible structured grids can result in grid representation of regions where no computation is needed. Finite element and finite volume methods map naturally to unstructured grids and are used commonly in hydrology, ocean modeling, and many other applications.

In order to provide support for application codes using unstructured grids, the ESMF library provides a class for representing unstructured grids called the Mesh. Fields can be created on a Mesh to hold data. Fields created on a Mesh can also be used as either the source or destination or both of an interpolation (i.e. an ESMF_FieldRegridStore() call) which allows data to be moved between unstructured grids. This section describes the Mesh and how to create and use them in ESMF.

32.1.1  Mesh representation in ESMF

A Mesh in ESMF is constructed of nodes and elements.

A node, also known as a vertex or corner, is a part of a Mesh which represents a single point. Coordinate information is set in a node.
An **element**, also known as a cell, is a part of a mesh which represents a small region of space. Elements are described in terms of a connected set of nodes which represent locations along their boundaries.

Field data may be located on either the nodes or elements of a Mesh.

The dimension of a Mesh in ESMF is specified with two parameters: the **parametric dimension** and the **spatial dimension**.

The **parametric dimension** of a Mesh is the dimension of the topology of the Mesh. This can be thought of as the dimension of the elements which make up the Mesh. For example, a Mesh composed of triangles would have a parametric dimension of 2, whereas a Mesh composed of tetrahedra would have a parametric dimension of 3.

The **spatial dimension** of a Mesh is the dimension of the space the Mesh is embedded in. In other words, it is the number of coordinate dimensions needed to describe the location of the nodes making up the Mesh.

For example, a Mesh constructed of squares on a plane would have a parametric dimension of 2 and a spatial dimension of 2. If that same Mesh were used to represent the 2D surface of a sphere, then the Mesh would still have a parametric dimension of 2, but now its spatial dimension would be 3.

### 32.1.2 Supported Meshes

The range of Meshes supported by ESMF are defined by several factors: dimension, element types, and distribution.

ESMF currently only supports Meshes whose number of coordinate dimensions (spatial dimension) is 2 or 3. The dimension of the elements in a Mesh (parametric dimension) must be less than or equal to the spatial dimension, but also must be either 2 or 3. This means that a Mesh may be either 2D elements in 2D space, 3D elements in 3D space, or a manifold constructed of 2D elements embedded in 3D space.

ESMF supports a range of elements for each Mesh parametric dimension. For a parametric dimension of 2, the native supported element types are triangles and quadrilaterals. In addition to these, ESMF supports 2D polygons with any number of sides. Internally these are represented as sets of triangles, but to the user should behave like any other element. For a parametric dimension of 3, the supported element types are tetrahedrons and hexahedrons. See Section [32.2.1](#) for diagrams of these. The Mesh supports any combination of element types within a particular dimension, but types from different dimensions may not be mixed. For example, a Mesh cannot be constructed of both quadrilaterals and tetrahedra.

ESMF currently only supports distributions where every node on a PET must be a part of an element on that PET. In other words, there must not be nodes without a corresponding element on any PET.

### 32.2 Constants

#### 32.2.1 ESMF_MESHELEMTYPE

**DESCRIPTION:**
An ESMF Mesh can be constructed from a combination of different elements. The type of elements that can be used in a Mesh depends on the Mesh’s parametric dimension, which is set during Mesh creation. The following are the valid Mesh element types for each valid Mesh parametric dimension (2D or 3D).

```
3
/  \        4
   |        3
```

For a Mesh with parametric dimension of 2 ESMF supports two native element types (illustrated above), but also supports polygons with more sides. Internally these polygons are represented as a set of triangles, but to the user should behave like other elements. To specify the non-native polygons in the `elementType` argument use the number of corners of the polygon (e.g. for a pentagon use 5). The connectivity for a polygon should be specified in counter-clockwise order. The following table summarizes this information:

<table>
<thead>
<tr>
<th>Element Type</th>
<th>Number of Nodes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESMF_MESHELEMTYPE_TRI</td>
<td>3</td>
<td>A triangle</td>
</tr>
<tr>
<td>ESMF_MESHELEMTYPE_QUAD</td>
<td>4</td>
<td>A quadrilateral (e.g. a rectangle)</td>
</tr>
<tr>
<td>N</td>
<td>N</td>
<td>An N-gon (e.g. if N=5 a pentagon)</td>
</tr>
</tbody>
</table>

For a Mesh with parametric dimension of 3 the valid element types (illustrated above) are:

<table>
<thead>
<tr>
<th>Element Type</th>
<th>Number of Nodes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESMF_MESHELEMTYPE_TETRA</td>
<td>4</td>
<td>A tetrahedron (NOT VALID IN BILINEAR OR PATCH REGRID)</td>
</tr>
<tr>
<td>ESMF_MESHELEMTYPE_HEX</td>
<td>8</td>
<td>A hexahedron (e.g. a cube)</td>
</tr>
</tbody>
</table>
32.2.2 ESMF_FILEFORMAT

DESCRIPTION:
This option is used by ESMF_MeshCreate to specify the type of the input grid file. See sections 12.4, 12.5, and 12.7 for more detailed description of the supported file formats.

The type of this flag is:
type (ESMF_FileFormat_Flag)

The valid values are:

ESMF_FILEFORMAT_SCRIP SCRIP format grid file. The SCRIP format is the format accepted by the SCRIP regridding tool. For Mesh creation, files of this type only work when the grid_rank in the file is equal to 1.

ESMF_FILEFORMAT_ESMFMESH ESMF unstructured grid file format. This format was developed by the ESMF team to match the capabilities of the Mesh class and to be efficient to convert to that class.

ESMF_FILEFORMAT_UGRID CF-convention unstructured grid file format. This format is a proposed extension to the CF-conventions for unstructured grid data model. Currently, only the 2D flexible mesh topology is supported in ESMF.

32.3 Use and Examples

This section describes the use of the ESMF Mesh class. It starts with an explanation and examples of creating a Mesh and then goes through other Mesh methods. This set of sections covers the use of the Mesh class interfaces, for further detail which applies to creating a Field on a Mesh, please see Section 25.3.18.

32.3.1 Mesh creation

To create a Mesh we need to set some properties of the Mesh as a whole, some properties of each node in the mesh and then some properties of each element which connects the nodes (for a definition of node and element please see Section 32.1.1).

For the Mesh as a whole we set its parametric dimension (parametricDim) and spatial dimension (spatialDim). A Mesh's parametric dimension can be thought of as the dimension of the elements which make up the Mesh. A Mesh's spatial dimension, on the other hand, is the is the number of coordinate dimensions needed to describe the location of the nodes making up the Mesh. (For a fuller definition of these terms please see Section 32.1.1).

The structure of the per node and element information used to create a Mesh is influenced by the Mesh distribution strategy. The Mesh class is distributed by elements. This means that a node must be present on any PET that contains an element associated with that node, but not on any other PET (a node can’t be on a PET without an element "home"). Since a node may be used by two or more elements located on different PETs, a node may be duplicated on multiple PETs. When a node is duplicated in this manner, one and only one of the PETs that contain the node must "own" the node. The user sets this ownership when they define the nodes during Mesh creation. When a Field is created on a Mesh, on each PET the Field is only created on the nodes which are owned by that PET. This means that the size of the Field memory on the PET can be smaller than the number of nodes used to create the Mesh on that PET. Please see Section 25.3.18 in Field for further explanation and examples of this issue and others in working with Fields on Meshes.

For each node in the Mesh we set three properties: the global id of the node (nodeIds), node coordinates (nodeCoords), and which PET owns the node (nodeOwners). The node id is a unique (across all PETs) integer attached to the particular node. It is used to indicate which nodes are the same when connecting together pieces
of the Mesh on different processors. The node coordinates indicate the location of a node in space and are used in the ESMF_FieldRegrid() functionality when interpolating. The node owner indicates which PET is in charge of the node. This is used when creating a Field on the Mesh to indicate which PET should contain a Field location for the data.

For each element in the Mesh we set three properties: the global id of the element (elementIds), the topology type of the element (elementTypes), and which nodes are connected together to form the element (elementConn). The element id is a unique (across all PETs) integer attached to the particular element. The element type describes the topology of the element (e.g. a triangle vs. a quadrilateral). The range of choices for the topology of the elements in a Mesh are restricted by the Mesh’s parametric dimension (e.g. a Mesh can’t contain a 2D element like a triangle, when its parametric dimension is 3D), but it can contain any combination of elements appropriate to its dimension. In particular, in 2D ESMF supports two native element types triangle and quadrilateral, but also provides support for polygons with any number of sides. These polygons are represented internally as sets of triangles, but to the user should behave like other elements. To specify a polygon with more than four sides, the element type should be set to the number of corners of the polygon (e.g. element type=6 for a hexagon). The element connectivity indicates which nodes are to be connected together to form the element. The number of nodes connected together for each element is implied by the elements topology type (elementTypes). It is IMPORTANT to note, that the entries in this list are NOT the global ids of the nodes, but are indices into the PET local lists of node info used in the Mesh Create. In other words, the element connectivity isn’t specified in terms of the global list of nodes, but instead is specified in terms of the locally described node info. One other important point about connectivities is that the order of the nodes in the connectivity list of an element is important. Please see Section 32.2.1 for diagrams illustrating the correct order of nodes in an element. In general, when specifying an element with parametric dimension 2, the nodes should be given in counter-clockwise order around the element.

Mesh creation may either be performed as a one step process using the full ESMF_MeshCreate() call, or may be done in three steps. The three step process starts with a more minimal ESMF_MeshCreate() call. It is then followed by the ESMF_MeshAddNodes() to specify nodes, and then the ESMF_MeshAddElements() call to specify elements. This three step sequence is useful to conserve memory because the node arrays being used for the ESMF_MeshAddNodes() call can be deallocated before creating the arrays to be used in the ESMF_MeshAddElements() call.

### 32.3.2 Create a small single PET Mesh in one step

This example is intended to illustrate the creation of a small Mesh on one PET. The reason for starting with a single PET case is so that the user can start to familiarize themselves with the concepts of Mesh creation without the added...
complication of multiple processors. Later examples illustrate the multiple processor case. This example creates the small 2D Mesh which can be seen in the figure above. Note that this Mesh consists of 9 nodes and 5 elements, where the elements are a mixture of quadrilaterals and triangles. The coordinates of the nodes in the Mesh range from 0.0 to 2.0 in both dimensions. The node ids are in the corners of the elements whereas the element ids are in the centers. The following section of code illustrates the creation of this Mesh.

! Set number of nodes
numNodes=9

! Allocate and fill the node id array.
allocate(nodeIds(numNodes))
nodeIds=(/1,2,3,4,5,6,7,8,9/)

! Allocate and fill node coordinate array.
! Since this is a 2D Mesh the size is 2x the
! number of nodes.
allocate(nodeCoords(2*numNodes))
nodeCoords=(/0.0,0.0, & ! node id 1
1.0,0.0, & ! node id 2
2.0,0.0, & ! node id 3
0.0,1.0, & ! node id 4
1.0,1.0, & ! node id 5
2.0,1.0, & ! node id 6
0.0,2.0, & ! node id 7
1.0,2.0, & ! node id 8
2.0,2.0 /) ! node id 9

! Allocate and fill the node owner array.
! Since this Mesh is all on PET 0, it’s just set to all 0.
allocate(nodeOwners(numNodes))
nodeOwners=0 ! everything on PET 0

! Set the number of each type of element, plus the total number.
umQuadElems=3
numTriElems=2
numTotElems=numQuadElems+numTriElems

! Allocate and fill the element id array.
allocate(elemIds(numTotElems))
elemIds=(/1,2,3,4,5/)

! Allocate and fill the element topology type array.
allocate(elemTypes(numTotElems))
elemTypes=(/ESMF_MESHELEMTYPE_QUAD, & ! elem id 1
ESMF_MESHELEMTYPE_TRI, & ! elem id 2
ESMF_MESHELEMTYPE_TRI, & ! elem id 3
ESMF_MESHELEMTYPE_QUAD, & ! elem id 4
ESMF_MESHELEMTYPE_QUAD/) ! elem id 5

! Allocate and fill the element connection type array.
Note that entries in this array refer to the positions in the nodeIds, etc. arrays and that the order and number of entries for each element reflects that given in the Mesh options section for the corresponding entry in the elemTypes array. The number of entries in this elemConn array is the number of nodes in a quad. (4) times the number of quad. elements plus the number of nodes in a triangle (3) times the number of triangle elements.

allocate(elemConn(4*numQuadElems+3*numTriElems))
elemConn=(/1,2,5,4, & ! elem id 1
2,3,5, & ! elem id 2
3,6,5, & ! elem id 3
4,5,8,7, & ! elem id 4
5,6,9,8/) ! elem id 5

! Create Mesh structure in 1 step
mesh=ESMF_MeshCreate(parametricDim=2,spatialDim=2, &
    nodeIds=nodeIds, nodeCoords=nodeCoords, &
    nodeOwners=nodeOwners, elementIds=elemIds,&
    elementTypes=elemTypes, elementConn=elemConn, &
    rc=localrc)

! After the creation we are through with the arrays, so they may be deallocated.
deallocate(nodeIds)
deallocate(nodeCoords)
deallocate(nodeOwners)
deallocate(elemIds)
deallocate(elemTypes)
deallocate(elemConn)

! At this point the mesh is ready to use. For example, as is illustrated here, to have a field created on it. Note that the Field only contains data for nodes owned by the current PET. Please see Section "Create a Field from a Mesh" under Field for more information on creating a Field on a Mesh.
field = ESMF_FieldCreate(mesh, ESMF_TYPEKIND_R8, rc=localrc)

32.3.3 Create a small single PET Mesh in three steps

This example is intended to illustrate the creation of a small Mesh in three steps on one PET. The Mesh being created is exactly the same one as in the last example (Section 32.3.2), but the three step process allows the creation to occur in a more memory efficient manner.

! Create the mesh structure setting the dimensions
mesh = ESMF_MeshCreate(parametricDim=2,spatialDim=2, rc=localrc)

! Set number of nodes
numNodes=9

! Allocate and fill the node id array.
allocate(nodeIds(numNodes))
nodeIds=(/1,2,3,4,5,6,7,8,9/)

! Allocate and fill node coordinate array.
! Since this is a 2D Mesh the size is 2x the
! number of nodes.
allocate(nodeCoords(2*numNodes))
nodeCoords=(/0.0,0.0, & ! node id 1
         1.0,0.0, & ! node id 2
         2.0,0.0, & ! node id 3
         0.0,1.0, & ! node id 4
         1.0,1.0, & ! node id 5
         2.0,1.0, & ! node id 6
         0.0,2.0, & ! node id 7
         1.0,2.0, & ! node id 8
         2.0,2.0 /) ! node id 9

! Allocate and fill the node owner array.
! Since this Mesh is all on PET 0, it’s just set to all 0.
allocate(nodeOwners(numNodes))
nodeOwners=0 ! everything on PET 0

! Add the nodes to the Mesh
call ESMF_MeshAddNodes(mesh, nodeIds=nodeIds, &
       nodeCoords=nodeCoords, nodeOwners=nodeOwners, rc=localrc)

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
! HERE IS THE POINT OF THE THREE STEP METHOD
! WE CAN DELETE THESE NODE ARRAYS BEFORE
! ALLOCATING THE ELEMENT ARRAYS, THEREBY
! REDUCING THE AMOUNT OF MEMORY NEEDED
! AT ONE TIME.
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
deallocate(nodeIds)
deallocate(nodeCoords)
deallocate(nodeOwners)

! Set the number of each type of element, plus the total number.
numQuadElems=3
numTriElems=2
numTotElems=numQuadElems+numTriElems

! Allocate and fill the element id array.
allocate(elemIds(numTotElems))
elemIds=(/1,2,3,4,5/)

! Allocate and fill the element topology type array.
allocate(elemTypes(numTotElems))
elemTypes=(/ESMF_MESHELEMTYPE_QUAD, & ! elem id 1
ESMF_MESHELEMTYPE_TRI, & ! elem id 2
ESMF_MESHELEMTYPE_TRI, & ! elem id 3
ESMF_MESHELEMTYPE_QUAD, & ! elem id 4
ESMF_MESHELEMTYPE_QUAD/) ! elem id 5

! Allocate and fill the element connection type array.
! Note that entries in this array refer to the
! positions in the nodeIds, etc. arrays and that
! the order and number of entries for each element
! reflects that given in the Mesh options
! section for the corresponding entry
! in the elemTypes array. The number of
! entries in this elemConn array is the
! number of nodes in a quad. (4) times the
! number of quad. elements plus the number
! of nodes in a triangle (3) times the number
! of triangle elements.
allocate(elemConn(4*numQuadElems+3*numTriElems))
elemConn=(/1,2,5,4, & ! elem id 1
2,3,5, & ! elem id 2
3,6,5, & ! elem id 3
4,5,8,7, & ! elem id 4
5,6,9,8/) ! elem id 5

! Finish the creation of the Mesh by adding the elements
call ESMF_MeshAddElements(mesh, elementIds=elemIds,&
   elementTypes=elemTypes, elementConn=elemConn, &
rcc=localrc)

! After the creation we are through with the arrays, so they may be
! deallocated.
deallocate(elemIds)
deallocate(elemTypes)
deallocate(elemConn)

! At this point the mesh is ready to use. For example, as is
! illustrated here, to have a field created on it. Note that
! the Field only contains data for nodes owned by the current PET.
! Please see Section "Create a Field from a Mesh" under Field
! for more information on creating a Field on a Mesh.
field = ESMF_FieldCreate(mesh, ESMF_TYPEKIND_R8, rc=localrc)

32.3.4 Create a small Mesh on 4 PETs in one step

  2.0  7 ------- 8       8 ------- 9
    |        |                |
    4        |                5
This example is intended to illustrate the creation of a small mesh on multiple PETs. This example creates the same small 2D mesh as the previous two examples (See Section 32.3.2 for a diagram), however, in this case the Mesh is broken up across 4 PETs. The figure above illustrates the distribution of the Mesh across the PETs. As in the previous diagram, the node ids are in the corners of the elements and the element ids are in the centers. In this figure '[' and ']' around a character indicate a node which is owned by another PET. The nodeOwner parameter indicates which PET owns the node. Note that the three step creation illustrated in Section 32.3.3 could also be used in a parallel Mesh creation such as this by simply interleaving the three calls in the appropriate places between the node and element array definitions.

! Break up what’s being set by PET
if (localPET .eq. 0) then !!! This part only for PET 0
  ! Set number of nodes
  numNodes=4

  ! Allocate and fill the node id array.
  allocate(nodeIds(numNodes))
  nodeIds=(/1,2,4,5/)!

  ! Allocate and fill node coordinate array.
  ! Since this is a 2D Mesh the size is 2x the
  ! number of nodes.
  allocate(nodeCoords(2*numNodes))
  nodeCoords=(/0.0,0.0, & ! node id 1
              1.0,0.0, & ! node id 2
              0.0,1.0, & ! node id 4
              1.0,1.0 /) ! node id 5

  ! Allocate and fill the node owner array.
  allocate(nodeOwners(numNodes))
  nodeOwners=(/0, & ! node id 1
! Set the number of each type of element, plus the total number.
numQuadElems=1
numTriElems=0
numTotElems=numQuadElems+numTriElems

! Allocate and fill the element id array.
allocate(elemIds(numTotElems))
elemIds=(/1/)

! Allocate and fill the element topology type array.
allocate(elemTypes(numTotElems))
elemTypes=(/ESMF_MESHELEMTYPE_QUAD/) ! elem id 1

! Allocate and fill the element connection type array.
! Note that entry are local indices
allocate(elemConn(4*numQuadElems+3*numTriElems))
elemConn=(/1,2,4,3/) ! elem id 1

else if (localPET .eq. 1) then !!! This part only for PET 1
! Set number of nodes
numNodes=4

! Allocate and fill the node id array.
allocate(nodeIds(numNodes))
nodeIds=(/2,3,5,6/)

! Allocate and fill node coordinate array.
! Since this is a 2D Mesh the size is 2x the
! number of nodes.
allocate(nodeCoords(2*numNodes))
nodeCoords=(/1.0,0.0, & ! node id 2
2.0,0.0, & ! node id 3
1.0,1.0, & ! node id 5
2.0,1.0 /) ! node id 6

! Allocate and fill the node owner array.
allocate(nodeOwners(numNodes))

deallocate(elemIds)
deallocate(elemTypes)
deallocate(elemConn)

! At this point the mesh is ready to use. For example, as is 
! illustrated here, to have a field created on it. Note that 
! the Field only contains data for nodes owned by the current PET. 
! Please see Section "Create a Field from a Mesh" under Field 
! for more information on creating a Field on a Mesh.
field = ESMF_FieldCreate(mesh, ESMF_TYPEKIND_R8, rc=localrc)

32.3.5 Create a copy of a Mesh with a new distribution

This example demonstrates the creation of a new Mesh which is a copy of an existing Mesh with a new distribution of the original Mesh’s nodes and elements. To create the new Mesh in this manner the user needs two DistGrids. One to describe the new distribution of the nodes. The other to describe the new distribution of the elements. In this example we create new DistGrids from a list of indices. The DistGrids are then used in the redistribution Mesh create interface which is overloaded to ESMF_MeshCreate(). In this example we redistribute the Mesh created in the previous example (Section 32.3.4) to the distribution pictured above. Note that for simplicity’s sake, the position of the Mesh in the diagram is basically the same, but the PET positions and node owners have been changed.

! Setup the new location of nodes and elements depending on the processor
if (localPet .eq. 0) then !!! This part only for PET 0
allocate(elemIds(1))
    elemIds=([5])
allocate(nodeIds(4))
nodeIds=(/5,6,8,9/)

else if (localPet .eq. 1) then !!! This part only for PET 1
allocate(elemIds(1))
elemIds=(/4/)

allocate(nodeIds(2))
nodeIds=(/7,4/)  

else if (localPet .eq. 2) then !!! This part only for PET 2
allocate(elemIds(2))
elemIds=(/1,2/)

allocate(nodeIds(2))
nodeIds=(/1,2/)  

else if (localPet .eq. 3) then !!! This part only for PET 3
allocate(elemIds(1))
elemIds=(/3/)

allocate(nodeIds(1))
nodeIds=(/3/)  

endif

! Create new node DistGrid
nodedistgrid=ESMF_DistGridCreate(nodeIds, rc=localrc)
if (localrc .ne. ESMF_SUCCESS) rc=ESMF_FAILURE

! Create new element DistGrid
elemdistgrid=ESMF_DistGridCreate(elemIds, rc=localrc)
if (localrc .ne. ESMF_SUCCESS) rc=ESMF_FAILURE

! Can now deallocate distribution lists
deallocate(elemIds)
deallocate(nodeIds)

! Create new redisted Mesh based on DistGrids
mesh2=ESMF_MeshCreate(mesh, &
    nodalDistgrid=nodedistgrid, &
    elementDistgrid=elemdistgrid, &
    rc=localrc)
if (localrc .ne. ESMF_SUCCESS) rc=ESMF_FAILURE

! At this point the mesh is ready to use. For example, as is
! illustrated here, to have a field created on it. Note that
! the Field only contains data for nodes owned by the current PET.
! Please see Section "Create a Field from a Mesh" under Field
for more information on creating a Field on a Mesh.

field = ESMF_FieldCreate(mesh2, ESMF_TYPEKIND_R8, rc=localrc)

32.3.6 Create a Mesh from an unstructured grid file

ESMF supports the creation of a Mesh from three grid file formats: the SCRIP format, the ESMF format or the proposed CF unstructured grid UGRID format. All three of these grid file formats are NetCDF files.

When creating a Mesh from a SCRIP format file, there are a number of options to control the output Mesh. The data is located at the center of the grid cell in a SCRIP grid; whereas the data is located at the corner of a cell in an ESMF Mesh object. Therefore, we create a Mesh object by default by constructing a "dual" mesh using the coordinates in the file. If the user wishes to not construct the dual mesh, the optional argument convertToDual may be used to control this behavior. When convertToDual is set to .false. the Mesh constructed from the file will not be the dual. This is necessary when using the Mesh as part of a conservative regridding operation in the ESMF_FieldRegridStore() call, so the weights are properly generated for the cell centers in the file.

The following example code depicts how to create a Mesh using a SCRIP file. Note that you have to set the filetypeflag to ESMF_FILEFORMAT_SCRIP.

    mesh = ESMF_MeshCreate(filename="data/ne4np4-pentagons.nc", &
    filetypeflag=ESMF_FILEFORMAT_SCRIP, rc=localrc)

As mentioned above ESMF also supports creating Meshes from the ESMF format. The ESMF format works better with the methods used to create an ESMF Mesh object, so less conversion needs to be done to create a Mesh, and thus this format is more efficient than SCRIP to use within ESMF. The ESMF format is also more general than the SCRIP format because it supports higher dimension coordinates and more general topologies. Currently, ESMF_MeshCreate() does not support conversion to a dual mesh for this format. All regrid methods are supported on Meshes in this format.

Here is an example of creating a Mesh from an ESMF unstructured grid file. Note that you have to set the filetypeflag to ESMF_FILEFORMAT_ESMFMESH.

    mesh = ESMF_MeshCreate(filename="data/ne4np4-esmf.nc", &
    filetypeflag=ESMF_FILEFORMAT_ESMFMESH, &
    rc=localrc)

32.3.7 Remove Mesh memory

There are two different levels that the memory in a Mesh can be removed. The first of these is the standard destroy call, ESMF_MeshDestroy(). As with other classes, this call removes all memory associated with the object, and afterwards the object can not be used further (i.e. should not be used in any methods). The second, which is unique to Mesh, is the ESMF_MeshFreeMemory() call. This call removes the connection and coordinate information associated with the Mesh, but leaves the distgrid information. The coordinate and connection information held in the Mesh can consume a large amount of memory for a big Mesh, so using this call can very significantly reduce the amount of memory used. However, once this method has been used on a Mesh there are some restriction on what may be done with it. Once a Mesh has had its memory freed using this method, any Field built on the Mesh can no longer be used as part of an ESMF_FieldRegridStore() call. However, because the distgrid information is still part of the Mesh, Fields built on such a Mesh can still be part of an ESMF_FieldRegrid() call (where the routehandle was generated previous to the ESMF_MeshFreeMemory() operation). Fields may also still be created on these Meshes. The following short piece of code illustrates the use of this call.
Here a Field built on a mesh may be used as part of an ESMF_FieldRegridStore() call. This call removes connection and coordinate information, significantly reducing the memory used by mesh, but limiting what can be done with it.

```fortran
call ESMF_MeshFreeMemory(mesh, rc=localrc)
```

Here a new Field may be built on mesh, or a field built on a mesh may be used as part of an ESMF_FieldRegrid() call.

```fortran
! Destroy the mesh
! call ESMF_MeshDestroy(mesh, rc=localrc)
```

Here mesh can’t be used for anything

### 32.3.8 Mesh Masking

There are two types of masking available in Mesh: node masking and element masking. These both work in a similar manner, but vary slightly in the details of setting the mask information during mesh creation.

For node masking, the mask information is set using the `nodeMask` argument to either `ESMF_MeshCreate()` or `ESMF_MeshAddNodes()`. When a regrid store method is called (e.g. `ESMF_FieldRegridStore()`) the mask values arguments (`srcMaskValues` and `dstMaskValues`) can then be used to indicate which particular values set in the `nodeMask` array indicate that the node should be masked. For example, when calling `ESMF_FieldRegridStore()` if `dstMaskValues` has been set to 1, then any node in the destination Mesh whose corresponding `nodeMask` value is 1 will be masked out (a node with any other value than 1 will not be masked).

For element masking, the mask information is set using the `elementMask` argument to either `ESMF_MeshCreate()` or `ESMF_MeshAddElements()`. In a similar manner to node masking, when a regrid store method is called (e.g. `ESMF_FieldRegridStore()`) the mask values arguments (`srcMaskValues` and `dstMaskValues`) can then be used to indicate which particular values set in the `elementMask` array indicate that the element should be masked. For example, when calling `ESMF_FieldRegridStore()` if `dstMaskValues` has been set to 1, then any element in the destination Mesh whose corresponding `elementMask` value is 1 will be masked out (an element with any other value than 1 will not be masked).

### 32.4 Class API

#### 32.4.1 ESMF_MeshAssignment(=) - Mesh assignment

**INTERFACE:**

```fortran
interface assignment(=)
    mesh1 = mesh2
end interface
```

**ARGUMENTS:**

type(ESMF_Mesh) :: mesh1
type(ESMF_Mesh) :: mesh2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign mesh1 as an alias to the same ESMF Mesh object in memory as mesh2. If mesh2 is invalid, then mesh1 will be equally invalid after the assignment.

The arguments are:

mesh1 The ESMF_Mesh object on the left hand side of the assignment.

mesh2 The ESMF_Mesh object on the right hand side of the assignment.

32.4.2 ESMF_MeshOperator(==) - Mesh equality operator

INTERFACE:

interface operator(==)
  if (mesh1 == mesh2) then ... endif
  OR
  result = (mesh1 == mesh2)
endif

RETURN VALUE:

logical :: result

ARGUMENTS:

  type(ESMF_Mesh), intent(in) :: mesh1
  type(ESMF_Mesh), intent(in) :: mesh2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether mesh1 and mesh2 are valid aliases to the same ESMF Mesh object in memory. For a more general comparison of two ESMF Meshes, going beyond the simple alias test, the ESMF_MeshMatch() function (not yet implemented) must be used.

The arguments are:
**32.4.3 ESMF_MeshOperator(/=) - Mesh not equal operator**

**INTERFACE:**

```
interface operator(/=)
  if (mesh1 /= mesh2) then ... endif
  OR
  result = (mesh1 /= mesh2)
end interface
```

**RETURN VALUE:**

```logical :: result```

**ARGUMENTS:**

```
type(ESMF_Mesh), intent(in) :: mesh1
type(ESMF_Mesh), intent(in) :: mesh2```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Test whether mesh1 and mesh2 are not valid aliases to the same ESMF Mesh object in memory. For a more general comparison of two ESMF Meshes, going beyond the simple alias test, the ESMF_MeshMatch() function (not yet implemented) must be used.

The arguments are:

- **mesh1** The ESMF_Mesh object on the left hand side of the non-equality operation.
- **mesh2** The ESMF_Mesh object on the right hand side of the non-equality operation.

**32.4.4 ESMF_MeshAddElements - Add elements to a Mesh**

**INTERFACE:**
subroutine ESMF_MeshAddElements(mesh, elementIds, elementTypes, &
  elementConn, elementMask, elementArea, elementCoords, rc)

ARGUMENTS:

  type(ESMF_Mesh), intent(inout) :: mesh
  integer, intent(in) :: elementIds(:)
  integer, intent(in) :: elementTypes(:)
  integer, intent(in) :: elementConn(:)
  integer, intent(in), optional :: elementMask(:)
  real(ESMF_KIND_R8), intent(in), optional :: elementArea(:)
  real(ESMF_KIND_R8), intent(in), optional :: elementCoords(:)
  integer, intent(out), optional :: rc

DESCRIPTION:

This call is the third and last part of the three part mesh create sequence and should be called after the mesh is created with ESMF_MeshCreate() (32.4.6) and after the nodes are added with ESMF_MeshAddNodes() (32.4.5). This call adds the elements to the mesh and finalizes the create. After this call the Mesh is usable, for example a Field may be built on the created Mesh object and this Field may be used in an ESMF_FieldRegridStore() call.

The parameters to this call elementIds, elementTypes, and elementConn describe the elements to be created. The description for a particular element lies at the same index location in elementIds and elementTypes. Each entry in elementConn consists of the list of nodes used to create that element, so the connections for element $e$ in the elementIds array will start at $\text{number of nodes in element}(1) + \text{number of nodes in element}(2) + \cdots + \text{number of nodes in element}(e - 1) + 1$ in elementConn.

This call is collective across the current VM.

**elementIds** An array containing the global ids of the elements to be created on this PET. This input consists of a 1D array the size of the number of elements on this PET.

**elementTypes** An array containing the types of the elements to be created on this PET. The types used must be appropriate for the parametric dimension of the Mesh. Please see Section 32.2.1 for the list of options. This input consists of a 1D array the size of the number of elements on this PET.

**elementConn** An array containing the indexes of the sets of nodes to be connected together to form the elements to be created on this PET. The entries in this list are NOT node global ids, but rather each entry is a local index (1 based) into the list of nodes which were created on this PET by the previous ESMF_MeshAddNodes() call. In other words, an entry of 1 indicates that this element contains the node described by nodeIds(1), nodeCoords(1), etc. passed into the ESMF_MeshAddNodes() call on this PET. It is also important to note that the order of the nodes in an element connectivity list matters. Please see Section 32.2.1 for diagrams illustrating the correct order of nodes in a element. This input consists of a 1D array with a total size equal to the sum of the number of nodes in each element on this PET. The number of nodes in each element is implied by its element type in elementTypes. The nodes for each element are in sequence in this array (e.g. the nodes for element 1 are elementConn(1), elementConn(2), etc.).

[elementMask] An array containing values which can be used for element masking. Which values indicate masking are chosen via the srcMaskValues or dstMaskValues arguments to ESMF_FieldRegridStore() call. This input consists of a 1D array the size of the number of elements on this PET.

[elementArea] An array containing element areas. If not specified, the element areas are internally calculated. This input consists of a 1D array the size of the number of elements on this PET.
[elementCoords] An array containing the physical coordinates of the elements to be created on this PET. This input consists of a 1D array the size of the number of elements on this PET times the Mesh’s spatial dimension (spatialDim). The coordinates in this array are ordered so that the coordinates for an element lie in sequence in memory. (e.g. for a Mesh with spatial dimension 2, the coordinates for element 1 are in elementCoords(1) and elementCoords(2), the coordinates for element 2 are in elementCoords(3) and elementCoords(4), etc.).

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

32.4.5 ESMF_MeshAddNodes - Add nodes to a Mesh

**INTERFACE:**

```plaintext
subroutine ESMF_MeshAddNodes(mesh, nodeIds, nodeCoords, nodeOwners, &
   nodeMask, rc)
```

**ARGUMENTS:**

- `type(ESMF_Mesh), intent(inout) :: mesh`
- `integer, intent(in) :: nodeIds(:)`
- `real(ESMF_KIND_R8), intent(in) :: nodeCoords(:)`
- `integer, intent(in) :: nodeOwners(:)`
- `integer, intent(in), optional :: nodeMask(:)`
- `integer, intent(out), optional :: rc`

**DESCRIPTION:**

This call is the second part of the three part mesh create sequence and should be called after the mesh’s dimensions are set using ESMF_MeshCreate() (32.4.6). This call adds the nodes to the mesh. The next step is to call ESMF_MeshAddElements() (32.4.4).

The parameters to this call `nodeIds`, `nodeCoords`, and `nodeOwners` describe the nodes to be created on this PET. The description for a particular node lies at the same index location in `nodeIds` and `nodeOwners`. Each entry in `nodeCoords` consists of spatial dimension coordinates, so the coordinates for node n in the `nodeIds` array will start at \((n - 1) \times \text{spatialDim} + 1\).

- **nodeIds** An array containing the global ids of the nodes to be created on this PET. This input consists of a 1D array the size of the number of nodes on this PET.

- **nodeCoords** An array containing the physical coordinates of the nodes to be created on this PET. This input consists of a 1D array the size of the number of nodes on this PET times the Mesh’s spatial dimension (spatialDim). The coordinates in this array are ordered so that the coordinates for a node lie in sequence in memory. (e.g. for a Mesh with spatial dimension 2, the coordinates for node 1 are in `nodeCoords(1)` and `nodeCoords(2)`, the coordinates for node 2 are in `nodeCoords(3)` and `nodeCoords(4)`, etc.).

- **nodeOwners** An array containing the PETs that own the nodes to be created on this PET. If the node is shared with another PET, the value may be a PET other than the current one. Only nodes owned by this PET will have PET local entries in a Field created on the Mesh. This input consists of a 1D array the size of the number of nodes on this PET.
[nodeMask] An array containing values which can be used for node masking. Which values indicate masking are chosen via the srcMaskValues or dstMaskValues arguments to ESMF_FieldRegridStore() call. This input consists of a 1D array the size of the number of nodes on this PET.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

32.4.6 ESMF_MeshCreate - Create a Mesh as a 3 step process

INTERFACE:

! Private name; call using ESMF_MeshCreate()
function ESMF_MeshCreate3Part(parametricDim, spatialDim, &
coordSys, rc)

RETURN VALUE:

type(ESMF_Mesh) :: ESMF_MeshCreate3Part

ARGUMENTS:

integer, intent(in) :: parametricDim
integer, intent(in) :: spatialDim
type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
integer, intent(out), optional :: rc

DESCRIPTION:

This call is the first part of the three part mesh create sequence. This call sets the dimension of the elements in the mesh (parametricDim) and the number of coordinate dimensions in the mesh (spatialDim). The next step is to call ESMF_MeshAddNodes() (32.4.5) to add the nodes and then ESMF_MeshAddElements() (32.4.4) to add the elements and finalize the mesh.

This call is collective across the current VM.

parametricDim Dimension of the topology of the Mesh. (E.g. a mesh constructed of squares would have a parametric dimension of 2, whereas a Mesh constructed of cubes would have one of 3.)

spatialDim The number of coordinate dimensions needed to describe the locations of the nodes making up the Mesh. For a manifold, the spatial dimension can be larger than the parametric dim (e.g. the 2D surface of a sphere in 3D space), but it can’t be smaller.

[coordSys] The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10 If not specified then defaults to ESMF_COORDSYS_CART.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
32.4.7 ESMF_MeshCreate - Create a Mesh all at once

INTERFACE:

! Private name; call using ESMF_MeshCreate()
function ESMF_MeshCreate1Part(parametricDim, spatialDim, &
   nodeIds, nodeCoords, nodeOwners, nodeMask, &
   elementIds, elementTypes, elementConn, &
   elementMask, elementArea, elementCoords, &
   coordSys, rc)

RETURN VALUE:

   type(ESMF_Mesh) :: ESMF_MeshCreate1Part

ARGUMENTS:

   integer,     intent(in)     :: parametricDim
   integer,     intent(in)     :: spatialDim
   integer,     intent(in)     :: nodeIds(:)
   real(ESMF_KIND_R8), intent(in) :: nodeCoords(:)
   integer,     intent(in)     :: nodeOwners(:)
   integer,     intent(in), optional :: nodeMask(:)
   integer,     intent(in)     :: elementIds(:)
   integer,     intent(in)     :: elementTypes(:)
   integer,     intent(in)     :: elementConn(:)
   integer,     intent(in), optional :: elementMask(:)
   real(ESMF_KIND_R8), intent(in), optional :: elementArea(:)
   real(ESMF_KIND_R8), intent(in), optional :: elementCoords(:)
   type(ESMF_CoordSys_Flag), intent(in), optional :: coordSys
   integer,     intent(out), optional :: rc

DESCRIPTION:

Create a Mesh object in one step. After this call the Mesh is usable, for example, a Field may be built on the created Mesh object and this Field may be used in a ESMF_FieldRegridStore() call.

This call sets the dimension of the elements in the mesh (parametricDim) and the number of coordinate dimensions in the mesh (spatialDim). It then creates the nodes, and then creates the elements by connecting together the nodes.

The parameters to this call nodeIds, nodeCoords, and nodeOwners describe the nodes to be created on this PET. The description for a particular node lies at the same index location in nodeIds and nodeOwners. Each entry in nodeCoords consists of spatial dimension coordinates, so the coordinates for node $n$ in the nodeIds array will start at $(n-1) \times \text{spatialDim} + 1$.

The parameters to this call elementIds, elementTypes, and elementConn describe the elements to be created. The description for a particular element lies at the same index location in elementIds and elementTypes. Each entry in elementConn consists of the list of nodes used to create that element, so the connections for element $e$ in the elementIds array will start at $\sum_{i=1}^{e-1} \text{number_of_nodes_in_element}(i) + 1$ in elementConn.

This call is collective across the current VM.

parametricDim  Dimension of the topology of the Mesh. (E.g. a mesh constructed of squares would have a parametric dimension of 2, whereas a Mesh constructed of cubes would have one of 3.)
spatialDim The number of coordinate dimensions needed to describe the locations of the nodes making up the Mesh. For a manifold, the spatial dimension can be larger than the parametric dim (e.g. the 2D surface of a sphere in 3D space), but it can’t be smaller.

nodeIds An array containing the global ids of the nodes to be created on this PET. This input consists of a 1D array the size of the number of nodes on this PET.

nodeCoords An array containing the physical coordinates of the nodes to be created on this PET. This input consists of a 1D array the size of the number of nodes on this PET times the Mesh’s spatial dimension (spatialDim). The coordinates in this array are ordered so that the coordinates for a node lie in sequence in memory. (e.g. for a Mesh with spatial dimension 2, the coordinates for node 1 are in nodeCoords(1) and nodeCoords(2), the coordinates for node 2 are in nodeCoords(3) and nodeCoords(4), etc.).

nodeOwners An array containing the PETs that own the nodes to be created on this PET. If the node is shared with another PET, the value may be a PET other than the current one. Only nodes owned by this PET will have PET local entries in a Field created on the Mesh. This input consists of a 1D array the size of the number of nodes on this PET.

[nodeMask] An array containing values which can be used for node masking. Which values indicate masking are chosen via the srcMaskValues or dstMaskValues arguments to ESMF_FieldRegridStore() call. This input consists of a 1D array the size of the number of nodes on this PET.

elementIds An array containing the global ids of the elements to be created on this PET. This input consists of a 1D array the size of the number of elements on this PET.

elementTypes An array containing the types of the elements to be created on this PET. The types used must be appropriate for the parametric dimension of the Mesh. Please see Section 32.2.1 for the list of options. This input consists of a 1D array the size of the number of elements on this PET.

elementConn An array containing the indexes of the sets of nodes to be connected together to form the elements to be created on this PET. The entries in this list are NOT node global ids, but rather each entry is a local index (1 based) into the list of nodes to be created on this PET by this call. In other words, an entry of 1 indicates that this element contains the node described by nodeIds(1).nodeCoords(1), etc. on this PET. It is also important to note that the order of the nodes in an element connectivity list matters. Please see Section 32.2.1 for diagrams illustrating the correct order of nodes in a element. This input consists of a 1D array with a total size equal to the sum of the number of nodes contained in each element on this PET. The number of nodes in each element is implied by its element type in elementTypes. The nodes for each element are in sequence in this array (e.g. the nodes for element 1 are elementConn(1), elementConn(2), etc.).

[elementMask] An array containing values which can be used for element masking. Which values indicate masking are chosen via the srcMaskValues or dstMaskValues arguments to ESMF_FieldRegridStore() call. This input consists of a 1D array the size of the number of elements on this PET.

[elementArea] An array containing element areas. If not specified, the element areas are internally calculated. This input consists of a 1D array the size of the number of elements on this PET.

[elementCoords] An array containing the physical coordinates of the elements to be created on this PET. This input consists of a 1D array the size of the number of elements on this PET times the Mesh’s spatial dimension (spatialDim). The coordinates in this array are ordered so that the coordinates for an element lie in sequence in memory. (e.g. for a Mesh with spatial dimension 2, the coordinates for element 1 are in elementCoords(1) and elementCoords(2), the coordinates for element 2 are in elementCoords(3) and elementCoords(4), etc.).

coordSys The coordinate system of the grid coordinate data. For a full list of options, please see Section 50.10. If not specified then defaults to ESMF_COORDSYS_CART.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
32.4.8 ESMF_MeshCreate - Create a Mesh from a file

INTERFACE:

! Private name; call using ESMF_MeshCreate()
function ESMF_MeshCreateFromFile(filename, fileTypeFlag, &
   convertToDual, addUserArea, meshname, maskFlag, varname, &
   nodalDistgrid, elementDistgrid, rc)

RETURN VALUE:

    type(ESMF_Mesh) :: ESMF_MeshCreateFromFile

ARGUMENTS:

    character(len= * ), intent(in) :: filename
    type(ESMF_FileFormat_Flag), intent(in) :: fileTypeFlag
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: convertToDual
    logical, intent(in), optional :: addUserArea
    character(len= * ), intent(in), optional :: meshname
    type(ESMF_MeshLoc), intent(in), optional :: maskFlag
    character(len= * ), intent(in), optional :: varname
    type(ESMF_DistGrid), intent(in), optional :: nodalDistgrid
    type(ESMF_DistGrid), intent(in), optional :: elementDistgrid
    integer, intent(out), optional :: rc

DESCRIPTION:

Create a Mesh from a file. Provides options to convert to 3D and in the case of SCRIP format files, allows the dual of the mesh to be created.

This call is collective across the current VM.

filename The name of the grid file

filetypeflag The file type of the grid file to be read, please see Section 32.2.2 for a list of valid options.

[convertToDual] if .true., the mesh will be converted to its dual. If not specified, defaults to .true.. Converting to dual is only supported with file type ESMF_FILEFORMAT_SCRIP.

[addUserArea] if .true., the cell area will be read in from the GRID file. This feature is only supported when the grid file is in the SCRIP or ESMF format. If not specified, defaults to .false..

[maskFlag] If maskFlag is present, generate the mask using the missing_value attribute defined in 'varname' This flag is only supported when the grid file is in the UGRID format. The value could be either ESMF_MESHLOC_NODE or ESMF_MESHLOC_ELEMENT. If the value is ESMF_MESHLOC_NODE, the node mask will be generated and the variable has to be defined on the "node" (specified by its location attribute). If the value is ESMF_MESHLOC_ELEMENT, the element mask will be generated and the variable has to be defined on the "face" of the mesh. If the variable is not defined on the right location, no mask will be generated. If not specified, no mask will be generated.
[varname] If maskFlag is present, provide a variable name stored in the UGRID file and the mask will be generated using the missing value of the data value of this variable. The first two dimensions of the variable has to be the longitude and the latitude dimension and the mask is derived from the first 2D values of this variable even if this data is 3D, or 4D array. If not specified, defaults to empty string.

[nodalDistgrid] A 1D arbitrary distgrid describing the user-specified distribution of the nodes across the PETs.

[elementDistgrid] A 1D arbitrary distgrid describing the user-specified distribution of the elements across the PETs.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

32.4.9 ESMF_MeshCreate - Create a copy of a Mesh with a new distribution

INTERFACE:

! Private name; call using ESMF_MeshCreate()
function ESMF_MeshCreateRedist(mesh, nodalDistgrid, &
    elementDistgrid, rc)

RETURN VALUE:

type(ESMF_Mesh) :: ESMF_MeshCreateRedist

ARGUMENTS:

type(ESMF_Mesh), intent(in) :: mesh
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DistGrid), intent(in), optional :: nodalDistgrid
type(ESMF_DistGrid), intent(in), optional :: elementDistgrid
integer, intent(out), optional :: rc

DESCRIPTION:

Create a copy of an existing Mesh with a new distribution. Information in the Mesh such as connections, coordinates, areas, masks, etc. are automatically redistributed to the new Mesh. To redistribute data in Fields built on the orginal Mesh create a Field on the new Mesh and then use the Field redistribution functionality (ESMF_FieldRedistStore(), etc.). The equivalent methods can also be used for data in FieldBundles.

mesh The source Mesh to be redistributed.

[nodalDistgrid] A 1D arbitrary distgrid describing the new distribution of the nodes across the PETs.

[elementDistgrid] A 1D arbitrary distgrid describing the new distribution of the elements across the PETs.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
32.4.10  ESMF_MeshDestroy - Release resources associated with a Mesh

INTERFACE:

    subroutine ESMF_MeshDestroy(mesh, keywordenforcer, rc)

RETURN VALUE:

ARGUMENTS:

    type(ESMF_Mesh), intent(inout) :: mesh
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer,       intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This call removes internal memory associated with mesh. After this call mesh will no longer be usable.

The arguments are:

mesh  Mesh object to be destroyed.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

32.4.11  ESMF_MeshFreeMemory - Remove a Mesh and its memory

INTERFACE:

    subroutine ESMF_MeshFreeMemory(mesh, rc)

RETURN VALUE:

ARGUMENTS:

    type(ESMF_Mesh), intent(inout) :: mesh
    integer,       intent(out), optional :: rc
DESCRIPTION:

This call removes the portions of mesh which contain connection and coordinate information. After this call, Fields build on mesh will no longer be usable as part of an ESMF_FieldRegridStore() operation. However, after this call Fields built on mesh can still be used in an ESMF_FieldRegrid() operation if the routehandle was generated beforehand. New Fields may also be built on mesh after this call.

The arguments are:

mesh  Mesh object whose memory is to be freed.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

32.4.12  ESMF_MeshGet - Get object-wide Mesh information

INTERFACE:

subroutine ESMF_MeshGet(mesh, parametricDim, spatialDim, &
  nodalDistgrid, elementDistgrid, &
  numOwnedNodes, ownedNodeCoords, &
  numOwnedElements, isMemFreed, coordSys, rc)

RETURN VALUE:

ARGUMENTS:

ARGUMENTS:

type(ESMF_Mesh), intent(in) :: mesh
integer, intent(out), optional :: parametricDim
integer, intent(out), optional :: spatialDim
type(ESMF_DistGrid), intent(out), optional :: nodalDistgrid
type(ESMF_DistGrid), intent(out), optional :: elementDistgrid
integer, intent(out), optional :: numOwnedNodes
real(ESMF_KIND_R8), intent(out), optional :: ownedNodeCoords(:)
integer, intent(out), optional :: numOwnedElements
logical, intent(out), optional :: isMemFreed
type(ESMF_CoordSys_Flag), intent(out), optional :: coordSys
integer, intent(out), optional :: rc

DESCRIPTION:

Get various information from a mesh.

The arguments are:

mesh  Mesh object to retrieve information from.

[parametricDim]  Dimension of the topology of the Mesh. (E.g. a mesh constructed of squares would have a parametric dimension of 2, whereas a Mesh constructed of cubes would have one of 3.)
The number of coordinate dimensions needed to describe the locations of the nodes making up the Mesh. For a manifold, the spatial dimension can be larger than the parametric dim (e.g. the 2D surface of a sphere in 3D space), but it can’t be smaller.

A 1D arbitrary distgrid describing the distribution of the nodes across the PETs. Note that on each PET the distgrid will only contain entries for nodes owned by that PET. This is the DistGrid that would be used to construct the Array in a Field that is constructed on mesh.

A 1D arbitrary distgrid describing the distribution of elements across the PETs. Note that on each PET the distgrid will only contain entries for elements owned by that PET.

The number of local nodes which are owned by this PET. This is the number of PET local entries in the nodalDistgrid.

The coordinates for the local nodes. These coordinates will be in the proper order to correspond with the nodes in the nodalDistgrid returned by this call, and hence with a Field built on mesh. The size of the input array should be the spatial dim of mesh times numOwnedNodes.

The number of local elements which are owned by this PET. Note that every element is owned by the PET it resides on, so unlike for nodes, numOwnedElements is identical to the number of elements on the PET. It is also the number of PET local entries in the elementDistgrid.

Indicates if the coordinate and connection memory been freed from mesh. If so, it can no longer be used as part of an ESMF_FieldRegridStore() call.

The coordinate system of the grid coordinate data.

Return code; equals ESMF_SUCCESS if there are no errors.

33 XGrid Class

33.1 Description

An exchange grid represents the 2D boundary layer usually between the atmosphere on one side and ocean and land on the other in an Earth system model. There are dynamical and thermodynamical processes on either side of the boundary layer and on the boundary layer itself. The boundary layer exchanges fluxes from either side and adjusts boundary conditions for the model components involved. For climate modeling, it is critical that the fluxes transferred by the boundary layer are conservative.

The ESMF exchange grid is implemented as the ESMF_XGrid class. Internally it’s represented by a collection of the intersected cells between atmosphere and ocean/land grids. These polygonal cells can have irregular shapes and can be broken down into triangles facilitating a finite element approach.

There are two ways to create an ESMF_XGrid object from user supplied information. The first way to create an ESMF_XGrid takes two lists of ESMF_Grid or ESMF_Mesh that represent the model component grids on either side of the exchange grid. From the two lists of ESMF_Grid or ESMF_Mesh, information required for flux exchange calculation between any pair of the model components from either side of the exchange grid is computed. In addition, the internal representation of the ESMF_XGrid is computed and can be optionally stored as an ESMF_Mesh. This internal representation is the collection of the intersected polygonal cells as a result of merged ESMF_Meshes from both sides of the exchange grid. ESMF_Field can be created on the ESMF_XGrid and used for weight generation and regridding as the internal representation in the ESMF_XGrid has a complete geometrical description of the exchange grid.
The second way to create an ESMF_XGrid requires user to supply all necessary information to compute communication routehandle. A later call to ESMF_FieldRegridStore() with the xgrid and source and destination ESMF.Fields computes the ESMF_Routehandle object for matrix multiplication operation used in model remapping. 

ESMF_XGrid deals with 2 distinctive kinds of fraction for each Grid or Mesh cell involved in its creation. The following description applies to both ESMF_Grid and ESMF_Mesh involved in the ESMF_XGrid creation process. The first fraction quantity $f_1$ is the same as defined in direct Field regrid between a source and destination ESMF.Field pair, namely the fraction of a total Grid cell area $A$ that is used in weight generation. The second fraction quantity $f_2$ is a result of the Grid merging process when multiple ESMF.Fields or model components exist on one side of the exchange grid. To compute XGrid, the multiple ESMF.Grids are first merged together to form a super mesh. During the merging process, Grids that are of a higher priority clips into lower priority Grids, creating fractional cells in the lower priority Grids. Priority is a mechanism to resolve the claim of a surface region by multiple Grids. To conserve flux, any surface area can only be claimed by a unique Grid. This is a typical practice in earth system modelling, e.g. to handle land and ocean boundary.

In addition to the matrix multiply communication routehandle, ESMF_XGrid exports both $f_1$ and $f_2$ to the user through the ESMF_FieldRegridStore() method because each remapping pair has different $f_1$ and $f_2$ associated with it. $f_2$ from source Grid is folded directly in the calculated weight matrices since its used to calculate destination point flux density $F$. The global source flux is defined as $\sum_{g=1}^{n_{srcgrid}} \sum_{s=1}^{n_{srccell}} f_1 s f_2 s A_s F_s$. The global destination flux is defined as: $\sum_{g=1}^{n_{dstgrid}} \sum_{d=1}^{n_{dstcell}} \sum_{s=1}^{n_{intersect}} (w_{sd} F_s) f_2 d A_d$, $w_{sd}$ is the $f_2$ modified weight intersecting s-th source Grid cell with d-th destination Grid cell. It can be proved that this formulation of the fractions and weight calculation ensures first order global conservation of flux $F$ transferred from source grids to exchange grid, and from exchange grid to destination grids.

### 33.2 Constants

#### 33.2.1 ESMF_XGRIDSIDE

**DESCRIPTION:**
Specify which side of the ESMF_XGrid the current operation is taking place.

The type of this flag is:

```
type(ESMF_XGridSide_Flag)
```

The valid values are:

- **ESMF_XGRIDSIDE_A** A side of the eXchange Grid, corresponding to the A side of the Grids used to create an XGrid.
- **ESMF_XGRIDSIDE_B** B side of the eXchange Grid, corresponding to the B side of the Grids used to create an XGrid.
- **ESMF_XGRIDSIDE_BALANCED** The internally generated balanced side of the eXchange Grid in the middle.

### 33.3 Use and Examples

#### 33.3.1 Create an XGrid from Grids then use it for regridding

An ESMF_XGrid object can be created from Grids on either side of the exchange grid. Internally the weight matrices and index mapping are computed and stored in the XGrid, along with other necessary information for flux exchange calculation between any pair of model components used for the XGrid creation.
In this example, we create an XGrid from overlapping Grids on either side of the XGrid. Then we perform a flux exchange from one side to the other side of the XGrid.

We start by creating the Grids on both sides and associate coordinates with the Grids on the corner stagger. The Grids use global indexing and padding for coordinates on the corner stagger.

For details of Grid creation and coordinate use, please refer to Grid class documentation: §30.3.2.

! First Grid on side A
sideA(1) = ESMF_GridCreateNoPeriDim(maxIndex=(/20, 20/), &
    indexflag=ESMF_INDEX_GLOBAL, &
    gridEdgeLWidth=(/0,0/), gridEdgeUWidth=(/1,1/), &
    name='source Grid 1 on side A', rc=localrc)

! Second Grid on side A
sideA(2) = ESMF_GridCreateNoPeriDim(maxIndex=(/20, 10/), &
    indexflag=ESMF_INDEX_GLOBAL, &
    gridEdgeLWidth=(/0,0/), gridEdgeUWidth=(/1,1/), &
    name='source Grid 2 on side A', rc=localrc)

! Allocate coordinates for Grid corner stagger
do i = 1, 2
    call ESMF_GridAddCoord(sideA(i), staggerloc=ESMF_STAGGERLOC_CORNER, &
        rc=localrc)
enddo

Assign coordinate for the Grids on sideA at corner stagger.

! SideA first grid spans (0-20, 0-20) with 1.0x1.0 degree resolution
! X corner
call ESMF_GridGetCoord(sideA(1), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=1, &
    farrayPtr=coordX, rc=localrc)

! Y corner
call ESMF_GridGetCoord(sideA(1), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=2, &
    farrayPtr=coordY, rc=localrc)

doi = lbound(coordX,1), ubound(coordX,1)
doj = lbound(coordX, 2), ubound(coordX, 2)
    coordX(i,j) = (i-1)*1.0
    coordY(i,j) = (j-1)*1.0
enddo
enddo
! SideA second grid spans (14.3-24.3, 14.2-24.2) with 0.5x1.0 degree
! resolution X corner
call ESMF_GridGetCoord(sideA(2), localDE=0, &
                           staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=1, &
                           farrayPtr=coordX, rc=localrc)

! Y corner
call ESMF_GridGetCoord(sideA(2), localDE=0, &
                           staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=2, &
                           farrayPtr=coordY, rc=localrc)

do i = lbound(coordX,1), ubound(coordX,1)
do j = lbound(coordX, 2), ubound(coordX, 2)
    coordX(i,j) = 14.3+(i-1)*0.5
    coordY(i,j) = 14.2+(j-1)*1.0
endo
dendo

Create the destination grid on side B, only one Grid exists on side B. Also associate coordinate with the Grid:

sideB(1) = ESMF_GridCreateNoPeriDim(maxIndex=(/30, 30/), &
                                      indexflag=ESMF_INDEX_GLOBAL, &
                                      gridEdgeLWidth=(/0,0/), gridEdgeUWidth=(/1,1/), &
                                      name='source Grid 1 on side B', rc=localrc)

do i = 1, 1
call ESMF_GridAddCoord(sideB(i), staggerloc=ESMF_STAGGERLOC_CORNER, &
                          rc=localrc)
endo

! SideB grid spans (0-30, 0-30) with 1.0x1.0 degree resolution
! X corner
call ESMF_GridGetCoord(sideB(1), localDE=0, &
                           staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=1, &
                           farrayPtr=coordX, rc=localrc)

! Y corner
call ESMF_GridGetCoord(sideB(1), localDE=0, &
                           staggerLoc=ESMF_STAGGERLOC_CORNER, coordDim=2, &
                           farrayPtr=coordY, rc=localrc)

do i = lbound(coordX,1), ubound(coordX,1)
do j = lbound(coordX, 2), ubound(coordX, 2)
    coordX(i,j) = (i-1)*1.0
    coordY(i,j) = (j-1)*1.0
enddo
enddo

Create an ESMF_XGrid object from the two lists of Grids on side A and B. In this example both Grids on side A overlaps with the Grid on side B. It’s an error to have a Grid on either side that is spatially disjoint with the XGrid. Neither of the Grid on side A is identical to the Grid on side B. Calling the ESMF_XGridCreate() method is straightforward:

\[
xgrid = \text{ESMF\_XGridCreate(sideAGrid=sideA, sideBGrid=sideB, rc=localrc)}
\]

Create an ESMF_Field on the XGrid:

\[
field = \text{ESMF\_FieldCreate(xgrid, typekind=ESMF\_TYPEKIND\_R8, \&}
        rc=localrc)
\]

Query the Field for its Fortran data pointer and its exclusive bounds:

\[
\text{call ESMF\_FieldGet(field, farrayPtr=xfarrayPtr, \&}
            exclusiveLBound=xlb, exclusiveUBound=xub, rc=localrc)}
\]

Create src and dst Fields on side A and side B Grids.

\[
do \ i = 1, 2
    srcField(i) = \text{ESMF\_FieldCreate(sideA(i), \&}
                    typekind=ESMF\_TYPEKIND\_R8, rc=localrc)
enddo
\]

\[
do \ i = 1, 1
    dstField(i) = \text{ESMF\_FieldCreate(sideB(i), \&}
                    typekind=ESMF\_TYPEKIND\_R8, rc=localrc)
enddo
\]

The current implementation requires that Grids used to generate the XGrid must not match, i.e. they are different either topologically or geometrically or both. In this example, the first source Grid is topologically identical to the destination Grid but their geometric coordinates are different.

First we compute the regrid routehandles, these routehandles can be used repeatedly afterwards. Then we initialize the values in the Fields. Finally we execute the Regrid.
! Compute regrid routehandles. The routehandles can be used
! repeatedly afterwards.
! From A -> X
do i = 1, 2
   call ESMF_FieldRegridStore(xgrid, srcField(i), field, &
      routehandle=rh_src2xgrid(i), rc = localrc)
enddo
! from X -> B, retrieve the destination fraction Fields.
do i = 1, 1
   call ESMF_FieldRegridStore(xgrid, field, dstField(i), &
      dstFracField=dstFrac, dstMergeFracField=dstFrac2, &
      routehandle=rh_xgrid2dst(i), rc = localrc)
enddo

! Initialize values in the source Fields on side A
do i = 1, 2
   call ESMF_FieldGet(srcField(i), farrayPtr=farrayPtr, rc=localrc)
enddo
farrayPtr = i

! Initialize values in the destination Field on XGrid
xfarrayPtr = 0.0
! Initialize values in the destination Field on Side B
do i = 1, 1
   call ESMF_FieldGet(dstField(i), farrayPtr=farrayPtr, rc=localrc)
enddo
farrayPtr = 0.0

First we regrid from the Fields on side A to the Field on the XGrid:

! Execute regrid from A -> X
do i = 1, 2
   call ESMF_FieldRegrid(srcField(i), field, &
      routehandle=rh_src2xgrid(i), &
      zeroregion=ESMF_REGION_SELECT, rc = localrc)
enddo

Next we regrid from the Field on XGrid to the destination Field on side B:

! Execute the regrid store
do i = 1, 1
    call ESMF_FieldRegrid(field, dstField(i), &
    routehandle=rh_xgrid2dst(i), &
    rc = localrc)
enddo

After the regridding calls, the routehandle can be released by calling the ESMF_FieldRegridRelease() method.

do i = 1, 2
    call ESMF_FieldRegridRelease(routehandle=rh_src2xgrid(i), rc=localrc)
enddo

In the above example, we first set up all the required parameters to create an XGrid from user supplied input. Then we create Fields on the XGrid and the Grids on either side. Finally we use the ESMF_FieldRegrid() interface to perform a flux exchange from the source side to the destination side.

33.3.2 Using XGrid in Earth System modeling

A typical application in Earth System Modeling is to calculate flux exchange through the planetary boundary layer that can be represented by ESMF_XGrid. Atmosphere is above the planetary boundary layer while land and ocean are below the boundary layer. To create an XGrid, the land and ocean Grids that are usually different in resolution need to be merged first to create a super Mesh. This merging process is enabled through the support of masking.

The global land and ocean Grids need to be created with masking enabled. In practice, each Grid cell has an integer masking value attached to it. For examples using masking in ESMF_Grid please refer to section 30.3.14.

When calling the ESMF_XGridCreate() method, user can supply the optional arguments sideAMaskValues and sideBMaskValues. These arguments are one dimensional Fortran integer arrays. If any of the sideAMaskValues entry matches the masking value used in sideA Grid, the sideA Grid cell is masked out, vice versa for sideB. Thus by specifying different regions of a land and ocean Grids to be masked out, the two global Grids can be merged into a new global Mesh covering the entire Earth.

The following call shows how to use the ESMF_XGridCreate() method with the optional arguments sideAMaskValues and sideBMaskValues.

    xgrid = ESMF_XGridCreate(sideAGrid=sideA, sideBGrid=sideB, &
                              sideAMaskValues= (/2/), sideBMaskValues= (/3,4/), rc=localrc)

33.3.3 Create an XGrid from user input data then use it for regridding

Alternatively, XGrid can be created from Grids on either side, area and centroid information of XGrid cells, sparse matrix matmul information. The functionalities provided by the XGrid object is constrained by the user supplied input during its creation time.
In this example, we will set up a simple XGrid from overlapping Grids on either side of the XGrid. Then we perform a flux exchange from one side to the other side of the XGrid. The Grids are laid out in the following figure:

![Grid layout for simple XGrid creation example](image)

In this example, we will set up a simple XGrid from overlapping Grids on either side of the XGrid. Then we perform a flux exchange from one side to the other side of the XGrid. The Grids are laid out in the following figure:

Figure 20: Grid layout for simple XGrid creation example. Overlapping of 3 Grids (Green 2x2, Red 2x1, Blue 2x2). Green and red Grids on side A, blue Grid on side B, black indicates the resulting XGrid. Color coded sequence indices are shown. Physical coordinates are the tuples in parentheses, e.g. at the four corners of rectangular computational domain.

We start by creating the Grids on both sides and associate coordinates with the Grids. For details of Grid creation and coordinate use, please refer to Grid class documentation.

```fortran
sideA(1) = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=/(2,2/), &
                    coordDep1=/(1/), &
                    coordDep2=/(2/), &
                    name='source Grid 1 on side A', rc=localrc)

sideA(2) = ESMF_GridCreateNoPeriDim(minIndex=/(1,1/), maxIndex=/(2,1/), &
                    coordDep1=/(1/), &
                    coordDep2=/(2/), &
                    name='source Grid 2 on side A', rc=localrc)

do i = 1, 2
    call ESMF_GridAddCoord(sideA(i), staggerloc=ESMF_STAGGERLOC_CENTER, &
```
Coordinate for the Grids on sideA, refer to the Grid layout diagram for the interpretation of the coordinate values:

! SideA first grid
centroidA1X=(/0.5, 1.5/)
centroidA1Y=(/0.5, 1.5/)
call ESMF_GridGetCoord(sideA(1), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=1, &
    farrayPtr=coordX, rc=localrc)
coordX = centroidA1X
call ESMF_GridGetCoord(sideA(1), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=2, &
    farrayPtr=coordY, rc=localrc)
coordY = centroidA1Y

! SideA second grid
centroidA2X=(/0.5, 1.5/)
centroidA2Y=(/2.5/)
call ESMF_GridGetCoord(sideA(2), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=1, &
    farrayPtr=coordX, rc=localrc)
coordX = centroidA2X
call ESMF_GridGetCoord(sideA(2), localDE=0, &
    staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=2, &
    farrayPtr=coordY, rc=localrc)
coordY = centroidA2Y

Create the destination grid on side B, only one Grid exists on side B. Also associate coordinate with the Grid:

sideB(1) = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/2,2/), &
    coordDep1=(/1/), coordDep2=(/2/), &
    name='destination Grid on side B', rc=localrc)
do i = 1, 1
    call ESMF_GridAddCoord(sideB(i), staggerloc=ESMF_STAGGERLOC_CENTER, &
        rc=localrc)
enddo

! SideB grid
centroidBX=(/0.75, 1.75/)
centroidBY=(/0.75, 2.25/)
call ESMF_GridGetCoord(sideB(1), localDE=0, &
   staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=1, farrayPtr=coordX, &
   rc=localrc)

coordX = centroidBX
call ESMF_GridGetCoord(sideB(1), localDE=0, &
   staggerLoc=ESMF_STAGGERLOC_CENTER, coordDim=2, farrayPtr=coordY, &
   rc=localrc)

coordY = centroidBY

Set up the mapping indices and weights from A side to the XGrid. For details of sequence indices, factorIndexList, and factorList, please see section 27.2.17 in the reference manual. Please refer to the figure above for interpretation of the sequence indices used here.

In order to compute the destination flux on sideB through the XGrid as an mediator, we need to set up the factorList (weights) and factorIndexList (indices) for sparse matrix matmul in this formulation: \( \text{dst}\_\text{flux} = \mathbf{W}' \cdot \mathbf{W} \cdot \text{src}\_\text{flux} \), where \( \mathbf{W}' \) is the weight matrix from the XGrid to destination; and \( \mathbf{W} \) is the weight matrix from source to the XGrid. The weight matrix is generated using destination area weighted algorithm. Please refer to figure 20 for details.

! Set up mapping from A1 -> X
sparseMatA2X(1)%factorIndexList(1,1)=1 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,2)=2 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,3)=2 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,4)=3 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,5)=4 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,6)=4 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,7)=3 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,8)=4 ! src seq index (green)
sparseMatA2X(1)%factorIndexList(1,9)=4 ! src seq index (green)

sparseMatA2X(1)%factorIndexList(2,1)=1 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,2)=2 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,3)=3 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,4)=4 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,5)=5 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,6)=6 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,7)=7 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,8)=8 ! dst seq index (black)
sparseMatA2X(1)%factorIndexList(2,9)=9 ! dst seq index (black)

! Set up mapping from A2 -> X
sparseMatA2X(2)%factorIndexList(1,1)=1 ! src seq index (red)
sparseMatA2X(2)%factorIndexList(1,2)=2 ! src seq index (red)
sparseMatA2X(2)%factorIndexList(1,3)=2 ! src seq index (red)
sparseMatA2X(2)%factorIndexList(2,1)=10 ! dst seq index (black)
sparseMatA2X(2)%factorIndexList(2,2)=11 ! dst seq index (black)
sparseMatA2X(2)%factorIndexList(2,3)=12 ! dst seq index (black)

Set up the mapping weights from side A to the XGrid:

! Note that the weights are dest area weighted, they are ratio of areas with destination area as the denominator.
! Set up mapping weights from A1 -> X
sparseMatA2X(1)%factorList(:)=1.

! Set up mapping weights from A2 -> X
sparseMatA2X(2)%factorList(:)=1.

Set up the mapping indices and weights from the XGrid to B side:

! Set up mapping from X -> B
sparseMatX2B(1)%factorIndexList(1,1)=1 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,2)=2 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,3)=3 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,4)=4 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,5)=5 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,6)=6 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,7)=7 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,8)=8 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,9)=9 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,10)=10 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,11)=11 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(1,12)=12 ! src seq index (black)
sparseMatX2B(1)%factorIndexList(2,1)=1 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,2)=2 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,3)=3 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,4)=1 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,5)=1 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,6)=2 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,7)=3 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,8)=3 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,9)=4 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,10)=3 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,11)=3 ! dst seq index (blue)
sparseMatX2B(1)%factorIndexList(2,12)=4 ! dst seq index (blue)

! Set up mapping weights from X -> B
sparseMatX2B(1)%factorList(1)=4./9.
sparseMatX2B(1)%factorList(2)=2./9.
sparseMatX2B(1)%factorList(3)=2./3.
sparseMatX2B(1)%factorList(4)=2./9.
sparseMatX2B(1)%factorList(5)=1./9.
sparseMatX2B(1)%factorList(6)=1./3.
sparseMatX2B(1)%factorList(7)=2./9.
sparseMatX2B(1)%factorList(8)=1./9.
sparseMatX2B(1)%factorList(9)=1./3.
sparseMatX2B(1)%factorList(10)=4./9.
sparseMatX2B(1)%factorList(11)=2./9.
sparseMatX2B(1)%factorList(12)=2./3.

 Optionally the area can be setup to compute surface area weighted flux integrals:

 ! Set up destination areas to adjust weighted flux 
 xgrid_area(1) = 1. 
 xgrid_area(2) = 0.5 
 xgrid_area(3) = 0.5 
 xgrid_area(4) = 0.5 
 xgrid_area(5) = 0.25 
 xgrid_area(6) = 0.25 
 xgrid_area(7) = 0.5 
 xgrid_area(8) = 0.25 
 xgrid_area(9) = 0.25 
 xgrid_area(10) = 1. 
 xgrid_area(11) = 0.5 
 xgrid_area(12) = 0.5 

 Create an XGrid based on the user supplied regridding parameters:

 xgrid = ESMF_XGridCreateFromSparseMat(sideAGrid=sideA, & sideBGrid=sideB, area=xgrid_area, & centroid=centroid, sparseMatA2X=sparseMatA2X, & sparseMatX2B=sparseMatX2B, rc=localrc)

 Create an ESMF_Field on the XGrid:

 field = ESMF_FieldCreate(xgrid, typekind=ESMF_TYPEKIND_R8, & rc=localrc)

 Query the Field for its Fortran data pointer and its exclusive bounds:

 call ESMF_FieldGet(field, farrayPtr=xfarrayPtr, & exclusiveLBound=xlb, exclusiveUBound=xub, rc=localrc)

 Setup and initialize src and dst Fields on side A and side B Grids, source Fields have different source flux:

 do i = 1, 2 
 srcField(i) = ESMF_FieldCreate(sideA(i), & typekind=ESMF_TYPEKIND_R8, rc=localrc)
 call ESMF_FieldGet(srcField(i), farrayPtr=farrayPtr, rc=localrc)
The current implementation requires that Grids used to generate the XGrid must not match, i.e. they are different either topologically or geometrically or both. In this example, the first source Grid is topologically identical to the destination Grid but their geometric coordinates are different. This requirement will be relaxed in a future release.

First we compute the regrid routehandles, these routehandles can be used repeatedly afterwards. Then we initialize the values in the Fields. Finally we execute the Regrid.

! Compute regrid routehandles. The routehandles can be used ! repeatedly afterwards.
! From A -> X
   do i = 1, 2
      call ESMF_FieldRegridStore(xgrid, srcField(i), field, &
       routehandle=rh_src2xgrid(i), rc = localrc)
   enddo

! from X -> B
   do i = 1, 1
      call ESMF_FieldRegridStore(xgrid, field, dstField(i), &
       routehandle=rh_xgrid2dst(i), rc = localrc)
   enddo

! Initialize values in the source Fields on side A
   do i = 1, 2
      call ESMF_FieldGet(srcField(i), farrayPtr=farrayPtr, rc=localrc)
   farrayPtr = i
   enddo

! Initialize values in the destination Field on XGrid
   xfarrayPtr = 0.0
! Initialize values in the destination Field on Side B
   do i = 1, 1
      call ESMF_FieldGet(dstField(i), farrayPtr=farrayPtr, rc=localrc)
   farrayPtr = 0.0
   enddo
First we regrid from the Fields on side A to the Field on the XGrid:

```fortran
! Execute regrid from A -> X
do i = 1, 2
    call ESMF_FieldRegrid(srcField(i), field, &
        routehandle=rh_src2xgrid(i), &
        zeroregion=ESMF_REGION_SELECT, rc = localrc)
enddo
```

Next we regrid from the Field on XGrid to the destination Field on side B:

```fortran
! Execute the regrid store
do i = 1, 1
    call ESMF_FieldRegrid(field, dstField(i), &
        routehandle=rh_xgrid2dst(i), rc = localrc)
enddo
```

In the above example, we first set up all the required parameters to create an XGrid from user supplied input. Then we create Fields on the XGrid and the Grids on either side. Finally we use the `ESMF_FieldRegrid()` interface to perform a flux exchange from the source side to the destination side.

### 33.3.4 Query the XGrid for its internal information

One can query the XGrid for its internal information:

```fortran
call ESMF_XGridGet(xgrid, &
    ngridA=ngridA, & ! number of Grids on side A
    ngridB=ngridB, & ! number of Grids on side B
    sideAGrid=l_sideA, & ! list of Grids on side A
    sideBGrid=l_sideB, & ! list of Grids on side B
    area=l_area, & ! list of area of XGrid
    centroid=l_centroid, & ! list of centroid of XGrid
    distgridA=l_sideAdg, & ! list of Distgrids on side A
    distgridM = distgrid, & ! balanced distgrid
    sparseMatA2X=l_sparseMatA2X, & !sparse matrix matmul parameters A to X
    sparseMatX2B=l_sparseMatX2B, & !sparse matrix matmul parameters X to B
    rc=localrc)

call ESMF_XGridGet(xgrid, localDe=0, &
    elementCount=eleCount, & ! elementCount on the localDE
    exclusiveCount=ec, & ! exclusive count
    exclusiveLBound=elb, & ! exclusive lower bound
    exclusiveUBound=eub, & ! exclusive upper bound
    rc=localrc)
```
call ESMF_XGridGet(xgrid, &
    xgridSide=ESMF_XGRIDSIDE_A, & ! side of the XGrid to query
    gridIndex=1, & ! index of the distgrid
    distgrid=distgrid, & ! the distgrid returned
    rc=localrc)

33.3.5 Destroying the XGrid and other resources

Clean up the resources by destroy the XGrid and other objects:

! After the regridding is successful.
! Clean up all the allocated resources:
call ESMF_FieldDestroy(field, rc=localrc)

call ESMF_XGridDestroy(xgrid, rc=localrc)

do i = 1, 2
    call ESMF_FieldDestroy(srcField(i), rc = localrc)

call ESMF_GridDestroy(sideA(i), rc = localrc)
endo
do i = 1, 1
    call ESMF_FieldDestroy(dstField(i), rc = localrc)

call ESMF_GridDestroy(sideB(i), rc = localrc)
endo

dallocate(sparseMatA2X(1)%factorIndexList, sparseMatA2X(1)%factorList)
dallocate(sparseMatA2X(2)%factorIndexList, sparseMatA2X(2)%factorList)
dallocate(sparseMatX2B(1)%factorIndexList, sparseMatX2B(1)%factorList)

33.4 Restrictions and Future Work

33.4.1 Restrictions and Future Work

1. **CAUTION:** Any Grid or Mesh pair picked from the A side and B side of the XGrid cannot be topologically and geometrically identical on a local PET. This is expected to be relaxed in a future release.
33.5 Design and Implementation Notes

1. The XGrid class is implemented in Fortran, and as such is defined inside the framework by a XGrid derived type and a set of subprograms (functions and subroutines) which operate on that derived type. The XGrid class contains information needed to create Grid, Field, and communication routehandle.

2. XGrid follows the framework-wide convention of the *unison* creation and operation rule: All PETs which are part of the currently executing VM must create the same XGrids at the same point in their execution. In addition to the unison rule, XGrid creation also performs inter-PET communication within the current executing VM.

33.6 Class API

33.6.1 ESMF_XGridAssignment(=) - XGrid assignment

INTERFACE:

```fortran
interface assignment (=)
xgrid1 = xgrid2
```

ARGUMENTS:

```fortran
type(ESMF_XGrid) :: xgrid1
type(ESMF_XGrid) :: xgrid2
```

DESCRIPTION:

Assign xgrid1 as an alias to the same ESMF XGrid object in memory as xgrid2. If xgrid2 is invalid, then xgrid1 will be equally invalid after the assignment.

The arguments are:

- **xgrid1** The ESMF_XGrid object on the left hand side of the assignment.
- **xgrid2** The ESMF_XGrid object on the right hand side of the assignment.

---

33.6.2 ESMF_XGridOperator(==) - XGrid equality operator

INTERFACE:

```fortran
interface operator(==)
if (xgrid1 == xgrid2) then ... endif
OR
result = (xgrid1 == xgrid2)
```

RETURN VALUE:
logical :: result

ARGUMENTS:

    type(ESMF_XGrid), intent(in) :: xgrid1
    type(ESMF_XGrid), intent(in) :: xgrid2

DESCRIPTION:

Test whether xgrid1 and xgrid2 are valid aliases to the same ESMF XGrid object in memory. For a more general comparison of two ESMF XGrids, going beyond the simple alias test, the ESMF_XGridMatch() function (not yet implemented) must be used.

The arguments are:

xgrid1 The ESMF_XGrid object on the left hand side of the equality operation.
xgrid2 The ESMF_XGrid object on the right hand side of the equality operation.

33.6.3 ESMF_XGridOperator(/=) - XGrid not equal operator

INTERFACE:

    interface operator(/=)
      if (xgrid1 /= xgrid2) then ... endif
    end interface

OR

    result = (xgrid1 /= xgrid2)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_XGrid), intent(in) :: xgrid1
    type(ESMF_XGrid), intent(in) :: xgrid2

DESCRIPTION:

Test whether xgrid1 and xgrid2 are not valid aliases to the same ESMF XGrid object in memory. For a more general comparison of two ESMF XGrids, going beyond the simple alias test, the ESMF_XGridMatch() function (not yet implemented) must be used.

The arguments are:

xgrid1 The ESMF_XGrid object on the left hand side of the non-equality operation.
xgrid2 The ESMF_XGrid object on the right hand side of the non-equality operation.
33.6.4 ESMF_XGridCreate - Create an XGrid from lists of Grids and Meshes

INTERFACE:

function ESMF_XGridCreate(&
    sideAGrid, sideAMesh, &
    sideBGrid, sideBMesh, &
    sideAGridPriority, sideAMeshPriority, &
    sideBGridPriority, sideBMeshPriority, &
    sideAMaskValues, sideBMaskValues, &
    storeOverlay, &
    name, rc)

RETURN VALUE:

type(ESMF_XGrid) :: ESMF_XGridCreate

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Grid), intent(in), optional :: sideAGrid(:)
type(ESMF_Mesh), intent(in), optional :: sideAMesh(:)
type(ESMF_Grid), intent(in), optional :: sideBGrid(:)
type(ESMF_Mesh), intent(in), optional :: sideBMesh(:)
integer, intent(in), optional :: sideAGridPriority(:)
integer, intent(in), optional :: sideAMeshPriority(:)
integer, intent(in), optional :: sideBGridPriority(:)
integer, intent(in), optional :: sideBMeshPriority(:)
integer(ESMF_KIND_I4), intent(in), optional :: sideAMaskValues(:)
integer(ESMF_KIND_I4), intent(in), optional :: sideBMaskValues(:)
logical, intent(in), optional :: storeOverlay
character(len=*), intent(in), optional :: name
integer, intent(out),optional :: rc

DESCRIPTION:

Create an XGrid from user supplied input: the list of Grids or Meshes on side A and side B, and other optional arguments. A user can supply both Grids and Meshes on one side to create the XGrid. By default, the Grids have a higher priority over Meshes but the order of priority can be adjusted by the optional GridPriority and MeshPriority arguments. The priority order of Grids and Meshes can also be interleaved by rearranging the optional GridPriority and MeshPriority arguments accordingly.

Sparse matrix multiply coefficients are internally computed and uniquely determined by the Grids or Meshes provided in sideA and sideB. User can supply a single ESMF_Grid or an array of ESMF_Grid on either side of the ESMF_XGrid. For an array of ESMF_Grid or ESMF_Mesh in sideA or sideB, a merging process concatenates all the ESMF_Grids into a super mesh represented by ESMF_Mesh. The super mesh is then used to compute the XGrid. Grid or Mesh objects in sideA and sideB arguments must have coordinates defined for the corners of a Grid cell. XGrid created this way can be potentially memory expensive, memory can be released by destroying XGrid after communication routinehandles are computed using ESMF_FieldRegridStore() method.

It is erroneous to specify identical Grid or Mesh object in sideA and sideB arguments. If sideA and sideB have a single Grid or Mesh object, then it's erroneous if the two Grids or Meshes do not overlap. It is also erroneous to specify Grid or Mesh object in sideA or sideB that is spatially disjoint from the ESMF_XGrid.
This call is *collective* across the current VM. For more details please refer to the description of the XGrid class. For an example and associated documentation using this method see section 33.3.1

The arguments are:

- **sideAGrid**: Parametric 2D Grids on side A, for example, these Grids can be either Cartesian 2D or Spherical.
- **sideAMesh**: Parametric 2D Meshes on side A, for example, these Meshes can be either Cartesian 2D or Spherical.
- **sideBGrid**: Parametric 2D Grids on side B, for example, these Grids can be either Cartesian 2D or Spherical.
- **sideBMesh**: Parametric 2D Meshes on side B, for example, these Meshes can be either Cartesian 2D or Spherical.
- **sideAGridPriority**: Priority array of Grids on side A during overlay generation. The priority arrays describe the priorities of Grids at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Grid of the highest priority to the lowest priority.
- **sideAMeshPriority**: Priority array of Meshes on side A during overlay generation. The priority arrays describe the priorities of Meshes at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Mesh of the highest priority to the lowest priority.
- **sideBGridPriority**: Priority of Grids on side B during overlay generation. The priority arrays describe the priorities of Grids at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Grid of the highest priority to the lowest priority.
- **sideBMeshPriority**: Priority array of Meshes on side B during overlay generation. The priority arrays describe the priorities of Meshes at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Mesh of the highest priority to the lowest priority.
- **sideAMaskValues**: Mask information can be set in the Grid (see 30.3.14) or Mesh (see 32.3.8) upon which the Field is built. The sideAMaskValues argument specifies the values in that mask information which indicate a point should be masked out. In other words, a location is masked if and only if the value for that location in the mask information matches one of the values listed in sideAMaskValues. If sideAMaskValues is not specified, no masking on side A will occur.
- **sideBMaskValues**: Mask information can be set in the Grid (see 30.3.14) or Mesh (see 32.3.8) upon which the Field is built. The sideBMaskValues argument specifies the values in that mask information which indicate a point should be masked out. In other words, a location is masked if and only if the value for that location in the mask information matches one of the values listed in sideBMaskValues. If sideBMaskValues is not specified, no masking on side B will occur.
- **storeOverlay**: Setting the storeOverlay optional argument to .false. (default) allows a user to bypass storage of the ESMF_Mesh used to represent the XGrid. Only a ESMF_DistGrid is stored to allow Field to be built on the XGrid. If the temporary mesh object is of interest, storeOverlay can be set to .true. so a user can retrieve it for future use.
- **name**: name of the xgrid object.
- **rc**: Return code; equals ESMF_SUCCESS only if the ESMF_XGrid is created.

### 33.6.5 ESMF_XGridCreateFromSparseMat an XGrid from raw input parameters

**INTERFACE:**
function ESMF_XGridCreateFromSparseMat(&
    sideAGrid,    sideAMesh, &
    sideBGrid,    sideBMesh, &
    sideAGridPriority, sideAMeshPriority, &
    sideBGridPriority, sideBMeshPriority, &
    sparseMatA2X, sparseMatX2A, sparseMatB2X, sparseMatX2B, &
    area, centroid, &
    name, &
    rc)

RETURN VALUE:

type(ESMF_XGrid) :: ESMF_XGridCreateFromSparseMat

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Grid), intent(in), optional :: sideAGrid(:)
type(ESMF_Mesh), intent(in), optional :: sideAMesh(:)
type(ESMF_Grid), intent(in), optional :: sideBGrid(:)
type(ESMF_Mesh), intent(in), optional :: sideBMesh(:)
integer, intent(in), optional :: sideAGridPriority(:)
integer, intent(in), optional :: sideAMeshPriority(:)
integer, intent(in), optional :: sideBGridPriority(:)
integer, intent(in), optional :: sideBMeshPriority(:)
type(ESMF_XGridSpec), intent(in), optional :: sparseMatA2X(:)
type(ESMF_XGridSpec), intent(in), optional :: sparseMatX2A(:)
type(ESMF_XGridSpec), intent(in), optional :: sparseMatB2X(:)
type(ESMF_XGridSpec), intent(in), optional :: sparseMatX2B(:)
real(ESMF_KIND_R8), intent(in), optional :: area(:)
real(ESMF_KIND_R8), intent(in), optional :: centroid(:, :)
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

Create an XGrid directly from user supplied sparse matrix parameters. User is responsible to supply all information necessary for communication calculation. For an example and associated documentation using this method see section 33.3.3

The arguments are:

[sideAGrid] Parametric 2D Grids on side A, for example, these Grids can be either Cartesian 2D or Spherical.
[sideAMesh] Parametric 2D Meshes on side A, for example, these Meshes can be either Cartesian 2D or Spherical.
[sideBGrid] Parametric 2D Grids on side B, for example, these Grids can be either Cartesian 2D or Spherical.
[sideBMesh] Parametric 2D Meshes on side B, for example, these Meshes can be either Cartesian 2D or Spherical.
[sideAGridPriority] Priority array of Grids on sideA during overlay generation. The priority arrays describe the priorities of Grids at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Grid of the highest priority to the lowest priority.
[sideAMeshPriority] Priority array of Meshes on sideA during overlay generation. The priority arrays describe the priorities of Meshes at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Mesh of the highest priority to the lowest priority.

[sideBGridPriority] Priority of Grids on sideB during overlay generation. The priority arrays describe the priorities of Grids at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Grid of the highest priority to the lowest priority.

[sideBMeshPriority] Priority array of Meshes on sideB during overlay generation. The priority arrays describe the priorities of Meshes at the overlapping region. Flux contributions at the overlapping region are computed in the order from the Mesh of the highest priority to the lowest priority.

[sparseMatA2X] indexlist from a Grid index space on side A to xgrid index space; indexFactorlist from a Grid index space on side A to xgrid index space.

[sparseMatX2A] indexlist from xgrid index space to a Grid index space on side A; indexFactorlist from xgrid index space to a Grid index space on side A.

[sparseMatB2X] indexlist from a Grid index space on side B to xgrid index space; indexFactorlist from a Grid index space on side B to xgrid index space.

[sparseMatX2B] indexlist from xgrid index space to a Grid index space on side B; indexFactorlist from xgrid index space to a Grid index space on side B.

[area] area of the xgrid cells.

[centroid] coordinates at the area weighted center of the xgrid cells.

[name] name of the xgrid object.

[rc] Return code; equals ESMF_SUCCESS only if the ESMF_XGrid is created.

33.6.6 ESMF_XGridDestroy - Release resources associated with an XGrid

INTERFACE:

    subroutine ESMF_XGridDestroy(xgrid, keywordenforcer, &
    rc)

ARGUMENTS:

    type(ESMF_XGrid), intent(inout) :: xgrid
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Destroys an ESMF_XGrid, releasing the resources associated with the object.

The arguments are:

xgrid  ESMF_XGrid object.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

### 33.6.7 ESMF_XGridGet - Get object-wide information from an XGrid

#### INTERFACE:

```plaintext
! Private name; call using ESMF_XGridGet()

subroutine ESMF_XGridGetDefault(xgrid, &
   sideAGrid, sideBGrid, sideAMesh, sideBMesh, &
   ngridA, ngridB, area, centroid, &
   distgridA, distgridB, distgridM, &
   dimCount, localDECount, &
   sparseMatA2X, sparseMatX2A, sparseMatB2X, sparseMatX2B, &
   name, &
   rc)
```

#### ARGUMENTS:

- `xgrid`  type(ESMF_XGrid), intent(in) :: xgrid
- `sideAGrid`  type(ESMF_Grid), intent(out), optional :: sideAGrid(:), sideBGrid(:)
- `sideAMesh`  type(ESMF_Mesh), intent(out), optional :: sideAMesh(:), sideBMesh(:)
- `ngridA`  integer, intent(out), optional :: ngridA, ngridB
- `area`  real(ESMF_KIND_R8), intent(out), optional :: area(:)
- `centroid`  real(ESMF_KIND_R8), intent(out), optional :: centroid(:,:), centroid(:,:)
- `distgridA`  type(ESMF_DistGrid), intent(out), optional :: distgridA(:)
- `distgridB`  type(ESMF_DistGrid), intent(out), optional :: distgridB(:)
- `distgridM`  type(ESMF_DistGrid), intent(out), optional :: distgridM
- `dimCount`  integer, intent(out), optional :: dimCount
- `localDECount`  integer, intent(out), optional :: localDECount
- `sparseMatA2X`  type(ESMF_XGridSpec), intent(out), optional :: sparseMatA2X(:)
- `sparseMatX2A`  type(ESMF_XGridSpec), intent(out), optional :: sparseMatX2A(:)
- `sparseMatB2X`  type(ESMF_XGridSpec), intent(out), optional :: sparseMatB2X(:)
- `sparseMatX2B`  type(ESMF_XGridSpec), intent(out), optional :: sparseMatX2B(:)
- `name`  character (len=*) intent(out), optional :: name
- `rc`  integer, intent(out), optional :: rc

#### DESCRIPTION:

Get information about XGrid

The arguments are:
xgrid  The ESMF_XGrid object used to retrieve information from.

[sideAGrid]  List of 2D Grids on side A
[sideBGrid]  List of 2D Grids on side B
[sideAMesh]  List of 2D Meshes on side A
[sideBMesh]  List of 2D Meshes on side B
[ngridA]  Number of Grids or Meshes on the A side
[ngridB]  Number of Grids or Meshes on the B side
[area]  Area of the xgrid cells
[centroid]  Coordinates at the area weighted center of the xgrid cells
[distgridA]  list of distgrids whose sequence index list is an overlap between a Grid on sideA and the xgrid object.
[distgridB]  list of distgrids whose sequence index list is an overlap between a Grid on sideB and the xgrid object.
[distgridM]  the distgrid whose sequence index list fully describes the xgrid object.
[dimCount]  dimension of the xgrid
[localDECount]  number of local DEs on local PET
[sparseMatA2X]  indexlist from a Grid index space on side A to xgrid index space indexFactorlist from a Grid index space on side A to xgrid index space
[sparseMatX2A]  indexlist from xgrid index space to a Grid index space on side A indexFactorlist from xgrid index space to a Grid index space on side A
[sparseMatB2X]  indexlist from a Grid index space on side B to xgrid index space indexFactorlist from a Grid index space on side B to xgrid index space
[sparseMatX2B]  indexlist from xgrid index space to a Grid index space on side B indexFactorlist from xgrid index space to a Grid index space on side B
[name]  name of the xgrid object.
[rc]  Return code; equals ESMF_SUCCESS only if the ESMF_XGrid is created.

33.6.8  ESMF_XGridGet - Get an individual DistGrid from an XGrid

INTERFACE:

    ! Private name; call using ESMF_XGridGet()
    subroutine ESMF_XGridGetDG(xgrid, distgrid, &
                                xgridside, gridindex, &
                                rc)

ARGUMENTS:
type(ESMF_XGrid), intent(in) :: xgrid

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_DistGrid), intent(out) :: distgrid

integer, intent(in), optional :: xgridside
integer, intent(in), optional :: gridindex
integer, intent(out), optional :: rc

DESCRIPTION:

Get a distgrid from XGrid from a specific side.

The arguments are:

**xgrid** The ESMF_XGrid object used to retrieve information from.

**distgrid** Distgrid whose sequence index list is an overlap between gridIndex-th Grid on xgridSide and the xgrid object.

**[xgridside]** Which side of the XGrid to retrieve the distgrid from (either ESMF_XGRIDSIDE_A, ESMF_XGRIDSIDE_B, or ESMF_XGRIDSIDE_BALANCED). If not passed in then defaults to ESMF_XGRIDSIDE_BALANCED.

**[gridindex]** If xgridSide is ESMF_XGRIDSIDE_A or ESMF_XGRIDSIDE_B then this index selects the Distgrid associated with the Grid on that side. If not provided, defaults to 1.

**[rc]** Return code; equals ESMF_SUCCESS only if the ESMF_XGrid is created.

33.6.9 ESMF_XGridGet - Get DE-local information from an XGrid

INTERFACE:

! Private name; call using ESMF_XGridGet()

subroutine ESMF_XGridGetEle(xgrid, localDE, &
   elementCount, exclusiveCount, exclusiveLBound, exclusiveUBound, &
   rc)

ARGUMENTS:

type(ESMF_XGrid), intent(in) :: xgrid

integer, intent(in) :: localDE

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: elementCount
integer, intent(out), optional :: exclusiveCount
integer, intent(out), optional :: exclusiveLBound
integer, intent(out), optional :: exclusiveUBound
integer, intent(out), optional :: rc

DESCRIPTION:
Get localDE specific information about XGrid

The arguments are:

**xgrid**  The ESMF\_XGrid object used to retrieve information from.
**localDE**  Local DE for which information is requested. Correct value is an element of [0,...,localDeCount-1]
**[elementCount]**  Number of elements in exclusive region per DE
**[exclusiveLBound]**  Lower bound of sequence indices in exclusive region per DE
**[exclusiveUBound]**  Upper bound of sequence indices in exclusive region per DE
**[rc]**  Return code; equals ESMF\_SUCCESS only if the ESMF\_XGrid is created.

### 34  DistGrid Class

#### 34.1  Description

The ESMF DistGrid class sits on top of the DELlayout class and holds domain information in index space. A DistGrid object captures the index space topology and describes its decomposition in terms of DEs. Combined with DELlayout and VM the DistGrid defines the data distribution of a domain decomposition across the computational resources of an ESMF Component.

The global domain is defined as the union of logically rectangular (LR) sub-domains or tiles. The DistGrid create methods allow the specification of such a multi-tile global domain and its decomposition into exclusive, DE-local LR regions according to various degrees of user specified constraints. Complex index space topologies can be constructed by specifying connection relationships between tiles during creation.

The DistGrid class holds domain information for all DEs. Each DE is associated with a local LR region. No overlap of the regions is allowed. The DistGrid offers query methods that allow DE-local topology information to be extracted, e.g. for the construction of halos by higher classes.

A DistGrid object only contains decomposable dimensions. The minimum rank for a DistGrid object is 1. A maximum rank does not exist for DistGrid objects, however, ranks greater than 7 may lead to difficulties with respect to the Fortran API of higher classes based on DistGrid. The rank of a DELlayout object contained within a DistGrid object must be equal to the DistGrid rank. Higher class objects that use the DistGrid, such as an Array object, may be of different rank than the associated DistGrid object. The higher class object will hold the mapping information between its dimensions and the DistGrid dimensions.

#### 34.2  Constants

##### 34.2.1  ESMF\_DISTGRIDMATCH

**DESCRIPTION:**

Indicates the level to which two DistGrid variables match.

The type of this flag is:

```
type(ESMF\_DistGridMatch\_Flag)
```

The valid values are:
ESMF_DISTGRIDMATCH_INVALID: Indicates a non-valid matching level.

ESMF_DISTGRIDMATCH_NONE: The lowest valid level of DistGrid matching. This indicates that the DistGrid variables don’t match at any of the higher levels.

ESMF_DISTGRIDMATCH_EXACT: All the DistGrid pieces except the name match between the two DistGrid variables.

ESMF_DISTGRIDMATCH_ALIAS: Both DistGrid variables are aliases to the exact same DistGrid object in memory.

34.3 Use and Examples

The following examples demonstrate how to create, use and destroy DistGrid objects. In order to produce complete and valid DistGrid objects all of the ESMF_DistGridCreate() calls require to be called in unison i.e. on all PETs of a component with a complete set of valid arguments.

34.3.1 Single tile DistGrid with regular decomposition

The minimum information required to create an ESMF_DistGrid object for a single tile with default decomposition are the corners of the tile in index space. The following call will create a 1D DistGrid for a 1D index space tile with elements from 1 through 1000.

\[
\text{distgrid} = \text{ESMF\_DistGridCreate}(\text{minIndex}=/(1/), \text{maxIndex}=/(1000/), \text{rc}=\text{rc})
\]

A default DELayout with 1 DE per PET will be created during ESMF_DistGridCreate(). The 1000 elements of the specified 1D tile will then be block decomposed across the available DEs, i.e. across all PETs. Hence, for 4 PETs the (min) \sim (max) corners of the DE-local LR regions will be:

- DE 0 - (1) \sim (250)
- DE 1 - (251) \sim (500)
- DE 2 - (501) \sim (750)
- DE 3 - (751) \sim (1000)

DistGrids with rank > 1 can also be created with default decompositions, specifying only the corners of the tile. The following will create a 2D DistGrid for a 5x5 tile with default decomposition.

\[
\text{distgrid} = \text{ESMF\_DistGridCreate}(\text{minIndex}=/(1,1/), \text{maxIndex}=/(5,5/), \text{rc}=\text{rc})
\]

The default decomposition for a DistGrid of rank \(N\) will be \((nDEs \times 1 \times \ldots \times 1)\), where \(nDEs\) is the number of DEs in the DELayout and there are \(N - 1\) factors of 1. For the 2D example above this means a \(4 \times 1\) regular decomposition if executed on 4 PETs and will result in the following DE-local LR regions:

- DE 0 - (1,1) \sim (2,5)
- DE 1 - (3,1) \sim (3,5)
- DE 2 - (4,1) \sim (4,5)
- DE 3 - (5,1) \sim (5,5)
In many cases the default decomposition will not suffice for higher rank DistGrids (rank $> 1$). For this reason a
decomposition descriptor \texttt{regDecomp} argument is available during \texttt{ESMF_DistGridCreate()}. The following
call creates a DistGrid on the same 2D tile as before, but now with a user specified regular decomposition of $2 \times 3 = 6$
DEs.

\begin{verbatim}
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
    regDecomp=(/2,3/), rc=rc)
\end{verbatim}

The default DE labeling sequence follows column major order for the \texttt{regDecomp} argument:

\begin{verbatim}
          -----------> 2nd dimension
            | 0 2 4
            | 1 3 5
\end{verbatim}

By default grid points along all dimensions are homogeneously divided between the DEs. The maximum element
count difference between DEs along any dimension is 1. The (min) $\sim$ (max) corners of the DE-local LR domains of
the above example are as follows:

- \textbf{DE 0} - (1,1) $\sim$ (3,2)
- \textbf{DE 1} - (4,1) $\sim$ (5,2)
- \textbf{DE 2} - (1,3) $\sim$ (3,4)
- \textbf{DE 3} - (4,3) $\sim$ (5,4)
- \textbf{DE 4} - (1,5) $\sim$ (3,5)
- \textbf{DE 5} - (4,5) $\sim$ (5,5)

The specifics of the tile decomposition into DE-local LR domains can be modified by the optional \texttt{decompflag}
argument. The following line shows how this argument is used to keep ESMF’s default decomposition in the first
dimension but move extra grid points of the second dimension to the last DEs in that direction. Extra elements occur
if the number of DEs for a certain dimension does not evenly divide its extent. In this example there are 2 extra grid
points for the second dimension because its extent is 5 but there are 3 DEs along this index space axis.

\begin{verbatim}
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
    regDecomp=(/2,3/), decompflag=(/ESMF_DECOMP_BALANCED, &
    ESMF_DECOMP_RESTLAST/), rc=rc)
\end{verbatim}

Now DE 4 and DE 5 will hold the extra elements along the 2nd dimension.

- \textbf{DE 0} - (1,1) $\sim$ (3,1)
- \textbf{DE 1} - (4,1) $\sim$ (5,1)
- \textbf{DE 2} - (1,2) $\sim$ (3,2)
- \textbf{DE 3} - (4,2) $\sim$ (5,2)
- \textbf{DE 4} - (1,3) $\sim$ (3,5)
- \textbf{DE 5} - (4,3) $\sim$ (5,5)

An alternative way of indicating the DE-local LR regions is to list the index space coordinate as given by the associated
DistGrid tile for each dimension. For this 2D example there are two lists (dim 1) / (dim 2) for each DE:
Information about DE-local LR regions in the latter format can be obtained from the DistGrid object by use of
ESMF_DistGridGet() methods:

allocate(dimExtent(2, 0:5)) ! (dimCount, deCount)
call ESMF_DistGridGet(distgrid, delayout=delayout, &
indexCountPDe=dimExtent, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
call ESMF_DELayoutGet(delayout, localDeCount=localDeCount, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
allocate(localDeToDeMap(0:localDeCount-1))
call ESMF_DELayoutGet(delayout, localDeToDeMap=localDeToDeMap, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
do localDe=0, localDeCount-1
  de = localDeToDeMap(localDe)
  do dim=1, 2
    allocate(localIndexList(dimExtent(dim, de))) ! allocate list
    ! to hold indices
    call ESMF_DistGridGet(distgrid, localDe=localDe, dim=dim, &
    indexList=localIndexList, rc=rc)
    if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
    deallocate(localIndexList)
  enddo
enddo
deallocate(localDeToDeMap)
deallocate(dimExtent)

The advantage of the localIndexList format over the min-/max-corner format is that it can be used directly for
DE-local to tile index dereferencing. Furthermore the localIndexList allows to express very general decomposi-
tions such as the cyclic decompositions in the first dimension generated by the following call:

distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
regDecomp=(/2,3/), &
decompflag=(/ESMF_DECOMP_CYCLIC,ESMF_DECOMP_RESTLAST/), rc=rc)

with decomposition:

DE 0 - (1,3,5) / (1)
DE 1 - (2,4) / (1)
DE 2 - (1,3,5) / (2)
DE 3 - (2,4) / (2)
DE 4 - (1,3,5) / (3,4,5)
DE 5 - (2,4) / (3,4,5)
Finally, a DistGrid object is destroyed by calling

```c
call ESMF_DistGridDestroy(distgrid, rc=rc)
```

### 34.3.2 DistGrid and DELayout

The examples of this section use the 2D DistGrid of the previous section to show the interplay between DistGrid and DELayout. By default, i.e. without specifying the `delayout` argument, a DELayout will be created during DistGrid creation that provides as many DEs as the DistGrid object requires. The implicit call to `ESMF_DELayoutCreate()` is issued with a fixed number of DEs and default settings in all other aspects. The resulting DE to PET mapping depends on the number of PETs of the current VM context. Assuming 6 PETs in the VM

```c
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
    regDecomp=(/2,3/), rc=rc)
```

will result in the following domain decomposition in terms of DEs

```
0  2  4
1  3  5
```

and their layout or distribution over the available PETs:

```
DE 0  -> PET 0
DE 1  -> PET 1
DE 2  -> PET 2
DE 3  -> PET 3
DE 4  -> PET 4
DE 5  -> PET 5
```

Running the same example on a 4 PET VM will not change the domain decomposition into 6 DEs as specified by

```
0  2  4
1  3  5
```

but the layout across PETs will now contain multiple DE-to-PET mapping with default cyclic distribution:

```
DE 0  -> PET 0
DE 1  -> PET 1
DE 2  -> PET 2
DE 3  -> PET 3
DE 4  -> PET 0
DE 5  -> PET 1
```

Sometimes it may be desirable for performance tuning to construct a DELayout with specific characteristics. For instance, if the 6 PETs of the above example are running on 3 nodes of a dual-SMP node cluster and there is a higher
communication load along the first dimension of the model than along the second dimension it would be sensible to place DEs according to this knowledge.

The following example first creates a DELayout with 6 DEs where groups of 2 DEs are to be in fast connection. This DELayout is then used to create a DistGrid.

```python
delayout = ESMF_DELayoutCreate(deCount=6, deGrouping=/(i/2,i=0,5)/, rc=rc)
distgrid = ESMF_DistGridCreate(minIndex=/(1,1/), maxIndex=/(5,5/), &
    regDecomp=/(2,3/), delayout=delayout, rc=rc)
```

This will ensure a distribution of DEs across the cluster resource in the following way:

```
0 2 4
1 3 5
SMP SMP SMP
```

The interplay between DistGrid and DELayout may at first seem complicated. The simple but important rule to understand is that DistGrid describes a domain decomposition and each domain is labeled with a DE number. The DELayout describes how these DEs are laid out over the compute resources of the VM, i.e. PETs. The DEs are purely logical elements of decomposition and may be relabeled to fit the algorithm or legacy code better. The following example demonstrates this by describing the exact same distribution of the domain data across the fictitious cluster of SMP-nodes with a different choice of DE labeling:

```python
delayout = ESMF_DELayoutCreate(deCount=6, deGrouping=/(mod(i,3),i=0,5)/, &
    rc=rc)
distgrid = ESMF_DistGridCreate(minIndex=/(1,1/), maxIndex=/(5,5/), &
    regDecomp=/(2,3/), deLabelList=/(0,3,1,4,2,5/), delay out=delayout, rc=rc)
```

Here the `deLabelList` argument changes the default DE label sequence from column major to row major. The DELayout compensates for this change in DE labeling by changing the `deGrouping` argument to map the first dimension to SMP nodes as before. The decomposition and layout now looks as follows:

```
0 1 2
3 4 5
SMP SMP SMP
```

Finally, in order to achieve a completely user-defined distribution of the domain data across the PETs of the VM a DELayout may be created from a `petMap` before using it in the creation of a DistGrid. If for instance the desired distribution of a 2 x 3 decomposition puts the DEs of the first row onto 3 separate PETs (PET 0, 1, 2) and groups the DEs of the second row onto PET 3 a `petMap` must first be setup that takes the DE labeling of the DistGrid into account. The following lines of code result in the desired distribution using column major DE labeling by first create a DELayout and then using it in the DistGrid creation.

```python
delayout = ESMF_DELayoutCreate(petMap=/(0,3,1,3,2,3/), rc=rc)
```
This decomposes the global domain into

\[
\begin{array}{ccc}
0 & 2 & 4 \\
1 & 3 & 5
\end{array}
\]

and associates the DEs to the following PETs:

- DE 0 -> PET 0
- DE 1 -> PET 3
- DE 2 -> PET 1
- DE 3 -> PET 3
- DE 4 -> PET 2
- DE 5 -> PET 3

### 34.3.3 Single tile DistGrid with decomposition by DE blocks

The examples of the previous sections showed how DistGrid objects with regular decompositions are created. However, in some cases a regular decomposition may not be specific enough. The following example shows how the `deBlockList` argument is used to create a DistGrid object with completely user-defined decomposition.

A single 5x5 LR domain is to be decomposed into 6 DEs. To this end a list is constructed that holds the min and max corners of all six DE LR blocks. The DE-local LR blocks are arranged as to cover the whole tile domain without overlap.

```fortran
allocate(deBlockList(2, 2, 6)) ! (dimCount, 2, deCount)
deBlockList(:,1,1) = (/1,1/) ! minIndex 1st deBlock
deBlockList(:,2,1) = (/3,2/) ! maxIndex 1st deBlock
deBlockList(:,1,2) = (/4,1/) ! minIndex 2nd deBlock
deBlockList(:,2,2) = (/5,2/) ! maxIndex 2nd deBlock
deBlockList(:,1,3) = (/1,3/) ! minIndex 3rd deBlock
deBlockList(:,2,3) = (/2,4/) ! maxIndex 3rd deBlock
deBlockList(:,1,4) = (/3,3/) ! minIndex 4th deBlock
deBlockList(:,2,4) = (/5,4/) ! maxIndex 4th deBlock
deBlockList(:,1,5) = (/1,5/) ! minIndex 5th deBlock
deBlockList(:,2,5) = (/3,5/) ! maxIndex 5th deBlock
deBlockList(:,1,6) = (/4,5/) ! minIndex 6th deBlock
deBlockList(:,2,6) = (/5,5/) ! maxIndex 6th deBlock
```

```
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
deBlockList=deBlockList, rc=rc)
```

### 34.3.4 Single tile DistGrid with periodic boundaries

By default the edges of all tiles have solid wall boundary conditions. Periodic boundary conditions can be imposed by specifying connections between tiles. For the single LR domain of the last section periodic boundaries along the first
dimension are imposed by adding a `connectionList` argument with only one element to the create call.

```fortran
allocate(connectionList(1))
```

The connection element holds information about `tileIndex_A`, `tileIndex_B`, `positionVector`, and `orientationVector`.

```fortran
call ESMF_DistGridConnectionSet(connection=connectionList(1),
    tileIndexA=1, tileIndexB=1, &
    positionVector=(/5, 0/), &
    orientationVector=(/1, 2/), &
    rc=rc)
```

The `tileIndexA` and `tileIndexB` arguments specify that this is a connection within tile 1. The `positionVector` indicates that there is no offset between tileB and tileA along the second dimension, but there is an offset of 5 along the first dimension (which in this case is the length of dimension 1). This aligns tileB (which is tile 1) right next to tileA (which is also tile 1).

The `orientationVector` fixes the orientation of the tileB index space to be the same as the orientation of tileA (it maps index 1 of tileA to index 1 of tileB and the same for index 2). The `orientationVector` could have been omitted in this case which corresponds to the default orientation.

The `connectionList` can now be used to create a `DistGrid` object with the desired boundary conditions.

```fortran
distgrid = ESMF_DistGridCreate(minIndex=(/1,1/), maxIndex=(/5,5/), &
    deBlockList=deBlockList, connectionList=connectionList, rc=rc)
```

```fortran
deallocate(connectionList)
```

This closes the tile along the first dimension on itself, thus imposing periodic boundaries along this direction.

### 34.3.5 2D multi-tile DistGrid with regular decomposition

Creating a `DistGrid` from a list of LR domains is a straightforward extension of the case with a single LR domain. The first four arguments of `ESMF_DistGridCreate()` are promoted to rank 2, the second dimension being the tile count index.

The following 2D multi-tile domain consisting of 3 LR tiles will be used in the examples of this section:

```
----------------------------------------> 2nd dim
|                                           |
| (1,11)------(1,20)                       |
|                                           |
| (10,11)---(10,20)                        |
```

740
The first step in creating a multi-tile global domain is to construct the minIndex and maxIndex arrays.

```fortran
allocate(minIndex(2,3)) ! (dimCount, number of tiles)
allocate(maxIndex(2,3)) ! (dimCount, number of tiles)
minIndex(:,1) = (/11,1/)
maxIndex(:,1) = (/20,10/)
minIndex(:,2) = (/11,11/)
maxIndex(:,2) = (/20,20/)
minIndex(:,3) = (/1,11/)
maxIndex(:,3) = (/10,20/)
```

Next the regular decomposition for each tile is set up in the regDecomp array. In this example each tile is associated with a single DE.

```fortran
allocate(regDecomp(2,3)) ! (dimCount, number of tiles)
regDecomp(:,1) = (/1,1/) ! one DE
regDecomp(:,2) = (/1,1/) ! one DE
regDecomp(:,3) = (/1,1/) ! one DE
```

Finally the DistGrid can be created by calling

```fortran
distgrid = ESMF_DistGridCreate(minIndexPTile=minIndex, &
           maxIndexPTile=maxIndex, regDecompPTile=regDecomp, rc=rc)
```

The default DE labeling sequence is identical to the tile labeling sequence and follows the sequence in which the tiles are defined during the create call. However, DE labels start at 0 whereas tile labels start at 1. In this case the DE labels look as:

```
  2
  0 1
```

Each tile can be decomposed differently into DEs. The default DE labeling follows the column major order for each tile. This is demonstrated in the following case where the multi-tile global domain is decomposed into 9 DEs,

```fortran
regDecomp(:,1) = (/2,2/) ! 4 DEs
```
regDecomp(:,2) = (/1,3/) ! 3 DEs
regDecomp(:,3) = (/2,1/) ! 2 DEs

distgrid = ESMF_DistGridCreate(minIndexPTile=minIndex, &
        maxIndexPTile=maxIndex, regDecompPTile=regDecomp, rc=rc)

resulting in the following decomposition:

```
+-------+-------+
| 7     |       |
+-------+-------+
      |       |
      | 8     |
+-------+-------+
   0 2   4 5 6
   1 3   
+-------+-------+
   0 2   4 5 6
   1 3   
+-------+-------+

DE 0 - (11,1) ~ (15,5)
DE 1 - (16,1) ~ (20,5)
DE 2 - (11,6) ~ (15,10)
DE 3 - (16,6) ~ (20,10)
DE 4 - (11,11) ~ (20,14)
DE 5 - (11,15) ~ (20,17)
DE 6 - (11,18) ~ (20,20)
DE 7 - (1,11) ~ (5,20)
DE 8 - (6,11) ~ (10,20)
```

The decompflag and deLabelList arguments can be used much like in the single LR domain case to overwrite the default grid decomposition (per tile) and to change the overall DE labeling sequence, respectively.

### 34.3.6 Arbitrary DistGrids with user-supplied sequence indices

The DistGrid class supports the communication methods of higher classes, like Array and Field, by associating a unique sequence index with each DistGrid index tuple. This sequence index can be used to address every Array or Field element. By default, the DistGrid does not actually generate and store the sequence index of each element. Instead a default sequence through the elements is implemented in the DistGrid code. This default sequence is used internally when needed.

The DistGrid class provides two ESMF_DistGridCreate() calls that allow the user to specify arbitrary sequence indices, overriding the use of the default sequence index scheme. The user sequence indices are passed to the DistGrid in form of 1d Fortran arrays, one array on each PET. The local size of this array on each PET determines the number of DistGrid elements on the PET. The supplied sequence indices must be unique across all PETs.

```
allocate(arbSeqIndexList(10)) ! each PET will have 10 elements

do i=1, 10
    arbSeqIndexList(i) = (i-1)*petCount + localPet ! initialize unique ! seq. indices
enddo
```
A default DELayout will be created automatically during `ESMF_DistGridCreate()`, associating 1 DE per PET.

```fortran
  distgrid = ESMF_DistGridCreate(arbSeqIndexList=arbSeqIndexList, rc=rc)
```

The user provided sequence index array can be deallocated once it has been used.

```fortran
  deallocate(arbSeqIndexList)
```

The `distgrid` object can be used just like any other DistGrid object. The "arbitrary" nature of `distgrid` will only become visible during Array or Field communication methods, where source and destination objects map elements according to the sequence indices provided by the associated DistGrid objects.

```fortran
  call ESMF_DistGridDestroy(distgrid, rc=rc)
```

The second `ESMF_DistGridCreate()` call, that accepts the `arbSeqIndexList` argument, allows the user to specify additional, regular DistGrid dimensions. These additional DistGrid dimensions are not decomposed across DEs, but instead are simply "added" or "multiplied" to the 1D arbitrary dimension.

The same `arbSeqIndexList` array as before is used to define the user supplied sequence indices.

```fortran
  allocate(arbSeqIndexList(10)) ! each PET will have 10 elements
  do i=1, 10
    arbSeqIndexList(i) = (i-1) * petCount + localPet ! initialize unique ! seq. indices
  enddo

  allocate(arbSeqIndexList(10)) ! each PET will have 10 elements
  do i=1, 10
    arbSeqIndexList(i) = (i-1) * petCount + localPet ! initialize unique ! seq. indices
  enddo
```

The additional DistGrid dimensions are specified in the usual manner using `minIndex` and `maxIndex` arguments. The `dimCount` of the resulting DistGrid is the size of the `minIndex` and `maxIndex` arguments plus 1 for the arbitrary dimension. The `arbDim` argument is used to indicate which or the resulting DistGrid dimensions is associated with the arbitrary sequence indices provided by the user.

```fortran
  distgrid = ESMF_DistGridCreate(arbSeqIndexList=arbSeqIndexList, &
  arbDim=1, minIndexPTile=(/1,1/), maxIndexPTile=(/5,7/), rc=rc)
```

```fortran
  deallocate(arbSeqIndexList)
```

```fortran
  call ESMF_DistGridDestroy(distgrid, rc=rc)
```

### 34.4 Restrictions and Future Work

- Multi-tile DistGrids from `deBlockList` are not yet supported.
- The `fastAxis` feature has not been implemented yet.
34.5 Design and Implementation Notes

This section will be updated as the implementation of the DistGrid class nears completion.

34.6 Class API

34.6.1 ESMF_DistGridAssignment(=) - DistGrid assignment

INTERFACE:

    interface assignment (=)
    distgrid1 = distgrid2

ARGUMENTS:

    type (ESMF_DistGrid) :: distgrid1
    type (ESMF_DistGrid) :: distgrid2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign distgrid1 as an alias to the same ESMF DistGrid object in memory as distgrid2. If distgrid2 is invalid, then distgrid1 will be equally invalid after the assignment.

The arguments are:

**distgrid1** The ESMF_DistGrid object on the left hand side of the assignment.

**distgrid2** The ESMF_DistGrid object on the right hand side of the assignment.

34.6.2 ESMF_DistGridOperator(==) - DistGrid equality operator

INTERFACE:

    interface operator (==)
    if (distgrid1 == distgrid2) then ... endif
    OR
    result = (distgrid1 == distgrid2)

RETURN VALUE:

    logical :: result
ARGUMENTS:

```plaintext
type(ESMF_DistGrid), intent(in) :: distgrid1
type(ESMF_DistGrid), intent(in) :: distgrid2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether `distgrid1` and `distgrid2` are valid aliases to the same ESMF DistGrid object in memory. For a more general comparison of two ESMF DistGrids, going beyond the simple alias test, the `ESMF_DistGridMatch()` function (not yet fully implemented) must be used.

The arguments are:

- **distgrid1**: The `ESMF_DistGrid` object on the left hand side of the equality operation.
- **distgrid2**: The `ESMF_DistGrid` object on the right hand side of the equality operation.

---

### 34.6.3 ESMF_DistGridOperator(/=) - DistGrid not equal operator

**INTERFACE:**

```plaintext
interface operator(/=)
  if (distgrid1 /= distgrid2) then ... endif
  OR
  result = (distgrid1 /= distgrid2)
end interface operator(/=)
```

**RETURN VALUE:**

```plaintext
logical :: result
```

**ARGUMENTS:**

```plaintext
  type(ESMF_DistGrid), intent(in) :: distgrid1
  type(ESMF_DistGrid), intent(in) :: distgrid2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**
Test whether distgrid1 and distgrid2 are not valid aliases to the same ESMF DistGrid object in memory. For a more general comparison of two ESMF DistGrids, going beyond the simple alias test, the ESMF_DistGridMatch() function (not yet fully implemented) must be used.

The arguments are:

**distgrid1** The ESMF_DistGrid object on the left hand side of the non-equality operation.

**distgrid2** The ESMF_DistGrid object on the right hand side of the non-equality operation.

### 34.6.4 ESMF_DistGridCreate - Create DistGrid object from DistGrid

**INTERFACE:**

```fortran
! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateDG(distgrid, &
    firstExtra, lastExtra, indexflag, connectionList, vm, rc)

RETURN VALUE:

type(ESMF_DistGrid) :: ESMF_DistGridCreateDG

ARGUMENTS:

    type(ESMF_DistGrid), intent(in) :: distgrid
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, target, intent(in), optional :: firstExtra(:)
    integer, target, intent(in), optional :: lastExtra(:)
    type(ESMF_Index_Flag), intent(in), optional :: indexflag
    type(ESMF_DistGridConnection), intent(in), optional :: connectionList(:)
    type(ESMF_VM), intent(in), optional :: vm
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

- **6.3.0r** Added argument `vm` to support object creation on a different VM than that of the current context.

**DESCRIPTION:**
Create a new DistGrid from an existing DistGrid, keeping the decomposition unchanged. The firstExtra and lastExtra arguments allow extra elements to be added at the first/last edge DE in each dimension. The method also allows the indexflag to be set. Further, if the connectionList argument is provided it will be used to set connections in the newly created DistGrid, otherwise the connections of the incoming DistGrid will be used. If neither firstExtra, lastExtra, indexflag, nor connectionList arguments are specified, the method reduces to a deep copy of the incoming DistGrid object.

The arguments are:

- **distgrid**  Incoming DistGrid object.
- **[firstExtra]** Extra elements on the edge of the first DEs along each dimension. The default is a zero vector.
- **[lastExtra]** Extra elements on the edge of the last DEs along each dimension. The default is a zero vector.
- **[indexflag]** Indicates whether the indices provided by the minIndex and maxIndex arguments are to be interpreted to form a global index space or not. The default is ESMF_INDEX_DELOCAL. See section [50.25] for a complete list of options.
- **[connectionList]** List of ESMF_DistGridConnection objects, defining connections between DistGrid tiles in index space. See section [34.7.1] for the associated Set() method.
- **[vm]** If present, the DistGrid object and the DELayout object are created on the specified ESMF_VM object. The default is to use the VM of the current context.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

### 34.6.5 ESMF_DistGridCreate - Create DistGrid object from DistGrid (multi-tile version)

**INTERFACE:**

```fortran
! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateDGT(distgrid, firstExtraPTile, &
     lastExtraPTile, indexflag, connectionList, vm, rc)
```

**RETURN VALUE:**

- type(ESMF_DistGrid) :: ESMF_DistGridCreateDGT

**ARGUMENTS:**

```fortran
  type(ESMF_DistGrid), intent(in) :: distgrid
  integer, target, intent(in) :: firstExtraPTile(:,:)
  integer, target, intent(in) :: lastExtraPTile(:,:)
```

--- The following arguments require argument keyword syntax (e.g. rc=rc). ---

```fortran
  type(ESMF_Index_Flag), intent(in), optional :: indexflag
  type(ESMF_DistGridConnection), intent(in), optional :: connectionList(:)
  type(ESMF_VM), intent(in), optional :: vm
  integer, intent(out), optional :: rc
```

**STATUS:**

747
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.3.0r Added argument vm to support object creation on a different VM than that of the current context.

DESCRIPTION:

Create a new DistGrid from an existing DistGrid, keeping the decomposition unchanged. The firstExtraPTile and lastExtraPTile arguments allow extra elements to be added at the first/last edge DE in each dimension. The method also allows the indexflag to be set. Further, if the connectionList argument provided in it will be used to set connections in the newly created DistGrid, otherwise the connections of the incoming DistGrid will be used. If neither firstExtraPTile, lastExtraPTile, indexflag, nor connectionList arguments are specified, the method reduces to a deep copy of the incoming DistGrid object.

The arguments are:

distgrid Incoming DistGrid object.

firstExtraPTile Extra elements on the edge of the first DEs along each dimension.

lastExtraPTile Extra elements on the edge of the last DEs along each dimension.

[indexflag] Indicates whether the indices provided by the minIndex and maxIndex arguments are to be interpreted to form a global index space or not. The default is ESMF_INDEX_DELOCAL. See section 50.25 for a complete list of options.

[connectionList] List of ESMF_DistGridConnection objects, defining connections between DistGrid tiles in index space. See section 34.7.1 for the associated Set() method.

[vm] If present, the DistGrid object and the DELayout object are created on the specified ESMF_VM object. The default is to use the VM of the current context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

34.6.6 ESMF_DistGridCreate - Create DistGrid object with regular decomposition

INTERFACE:

! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateRD(minIndex, maxIndex, regDecomp, &
decompflag, regDecompFirstExtra, regDecompLastExtra, deLabelList, &
indexflag, connectionList, delayout, vm, rc)

RETURN VALUE:
type(ESMF_DistGrid) :: ESMF_DistGridCreateRD

ARGUMENTS:

integer, intent(in) :: minIndex(:)
integer, intent(in) :: maxIndex(:)

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, target, intent(in), optional :: regDecomp(:)
type(ESMF_Decomp_Flag), target, intent(in), optional :: decompflag(:)
integer, target, intent(in), optional :: regDecompFirstExtra(:)
integer, target, intent(in), optional :: regDecompLastExtra(:)
type(ESMF_Index_Flag), target, intent(in), optional :: indexflag

type(ESMF_DistGridConnection), intent(in), optional :: connectionList(:)
type(ESMF_DELayout), intent(in), optional :: delayout

type(ESMF_VM), intent(out), optional :: vm

integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DistGrid from a single logically rectangular (LR) tile with regular decomposition. A regular decomposition is of the same rank as the tile and decomposes each dimension into a fixed number of DEs. A regular decomposition of a single tile is expressed by a single regDecomp list of DE counts in each dimension.

The arguments are:

minIndex  Global coordinate tuple of the lower corner of the tile.

maxIndex  Global coordinate tuple of the upper corner of the tile.

[regDecomp] List of DE counts for each dimension. The default decomposition will be deCount×1×...×1. The value of deCount for a default DELayout equals petCount, i.e. the default decomposition will be into as many DEs as there are PETs and the distribution will be 1 DE per PET.

[decompflag] List of decomposition flags indicating how each dimension of the tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions. See section 50.13 for a list of valid decomposition options.

[regDecompFirstExtra] Extra elements on the first DEs along each dimension in a regular decomposition. The default is a zero vector.

[regDecompLastExtra] Extra elements on the last DEs along each dimension in a regular decomposition. The default is a zero vector.

[deLabelList] List assigning DE labels to the default sequence of DEs. The default sequence is given by the column major order of the regDecomp argument.

[indexflag] Indicates whether the indices provided by the minIndex and maxIndex arguments are to be interpreted to form a global index space or not. The default is ESMF_INDEX_DELOCAL. See section 50.25 for a complete list of options.
List of ESMF_DistGridConnection objects, defining connections between DistGrid tiles in index space. See section 34.7.1 for the associated Set() method.

ESMF_DELayout object to be used. If a DELayout object is specified its deCount must match the number indicated by regDecomp. By default a new DELayout object will be created with the correct number of DES.

If present, the DistGrid object (and the DELayout object if not provided) are created on the specified ESMF_VM object. The default is to use the VM of the current context.

Return code; equals ESMF_SUCCESS if there are no errors.

34.6.7 ESMF_DistGridCreate - Create DistGrid object with DE blocks

INTERFACE:

! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateDB(minIndex, maxIndex, deBlockList, &
deLabelList, indexflag, connectionList, delayout, vm, rc)

RETURN VALUE:

type(ESMF_DistGrid) :: ESMF_DistGridCreateDB

ARGUMENTS:

integer, intent(in) :: minIndex(:)
integer, intent(in) :: maxIndex(:)
integer, intent(in), optional :: deBlockList(:,:,:)
integer, intent(in), optional :: deLabelList(:)
type(ESMF_Index_Flag), intent(in), optional :: indexflag
type(ESMF_DistGridConnection), intent(in), optional :: connectionList(:)
type(ESMF_DELayout), intent(in), optional :: delayout
type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DistGrid from a single logically rectangular (LR) tile with decomposition specified by deBlockList.

The arguments are:
**minIndex**  Global coordinate tuple of the lower corner of the tile.

**maxIndex**  Global coordinate tuple of the upper corner of the tile.

**deBlockList**  List of DE-local LR blocks. The third index of deBlockList steps through the deBlock elements, which are defined by the first two indices. The first index must be of size `dimCount` and the second index must be of size 2. Each 2D element of deBlockList defined by the first two indices hold the following information.

```
+---------------------------------------> 2nd index
| 1 2
| 1 minIndex(1) maxIndex(1)
| 2 minIndex(2) maxIndex(2)
| . minIndex(.) maxIndex(.)
| .
\v
1st index
```

It is required that there be no overlap between the LR segments defined by deBlockList.

**[deLabelList]**  List assigning DE labels to the default sequence of DEs. The default sequence is given by the column major order of the `regDecomp` argument.

**[indexflag]**  Indicates whether the indices provided by the `minIndex` and `maxIndex` arguments are to be interpreted to form a global index space or not. The default is `ESMF_INDEX_DELOCAL`. See section 50.25 for a complete list of options.

**[connectionList]**  List of `ESMF_DistGridConnection` objects, defining connections between DistGrid tiles in index space. See section 34.7.1 for the associated `Set()` method.

**[delayout]**  Optional `ESMF_DELayout` object to be used. By default a new DELayout object will be created with the correct number of DEs. If a DELayout object is specified its number of DEs must match the number indicated by `regDecomp`.

**[vm]**  Optional `ESMF_VM` object of the current context. Providing the VM of the current context will lower the method’s overhead.

**[rc]**  Return code; equals `ESMF_SUCCESS` if there are no errors.

### 34.6.8 ESMF_DistGridCreate - Create DistGrid object with regular decomposition (multi-tile version)

**INTERFACE:**

```fortran
! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateRDT(minIndexPTile, maxIndexPTile, &
   regDecompPTile, decompflagPTile, regDecompFirstExtraPTile,&
   regDecompLastExtraPTile, deLabelList, indexflag, connectionList, &
   delayout, vm, rc)
```

**RETURN VALUE:**

751
type(ESMF_DistGrid) :: ESMF_DistGridCreateRDT

ARGUMENTS:

integer, intent(in) :: minIndexPTile(:,:)
integer, intent(in) :: maxIndexPTile(:,:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Decomp_Flag), target, intent(in), optional :: decompflagPTile(:,:)
type(ESMF_DistGridConnection), intent(in), optional :: connectionList(:)
type(ESMF_DELayout), intent(in), optional :: delayout

type(ESMF_VM), intent(in), optional :: vm
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DistGrid on multiple logically rectangular (LR) tiles with regular decomposition. A regular decomposition is of the same rank as the tile and decomposes each dimension into a fixed number of DEs. A regular decomposition of a multi-tile DistGrid is expressed by a list of DE count vectors, one vector for each tile. Each vector contained in the regDecompPTile argument ascribes DE counts for each dimension. It is erroneous to provide more tiles than there are DEs.

The arguments are:

minIndexPTile The first index provides the global coordinate tuple of the lower corner of a tile. The second index indicates the tile number.

maxIndexPTile The first index provides the global coordinate tuple of the upper corner of a tile. The second index indicates the tile number.

[regDecompPTile] List of DE counts for each dimension. The second index indicates the tile number. The default decomposition will be $deCount \times 1 \times \cdots \times 1$. The value of $deCount$ for a default DELayout equals petCount, i.e. the default decomposition will be into as many DEs as there are PETs and the distribution will be 1 DE per PET.

[decompflagPTile] List of decomposition flags indicating how each dimension of each tile is to be divided between the DEs. The default setting is ESMF_DECOMP_BALANCED in all dimensions for all tiles. See section 50.13 for a list of valid decomposition flag options. The second index indicates the tile number.

[regDecompFirstExtraPTile] Extra elements on the first DEs along each dimension in a regular decomposition. The default is a zero vector. The second index indicates the tile number.

[regDecompLastExtraPTile] Extra elements on the last DEs along each dimension in a regular decomposition. The default is a zero vector. The second index indicates the tile number.

[deLabelList] List assigning DE labels to the default sequence of DEs. The default sequence is given by the column major order of the regDecompPTile elements in the sequence as they appear following the tile index.
**[indexflag]** Indicates whether the indices provided by the `minIndex` and `maxIndex` arguments are to be interpreted to form a global index space or not. The default is `ESMF_INDEX_DELOCAL`. See section 50.25 for a complete list of options.

**[connectionList]** List of `ESMF_DistGridConnection` objects, defining connections between DistGrid tiles in index space. See section 34.7.1 for the associated `Set()` method.

**[delayout]** Optional `ESMF_DELayout` object to be used. By default a new DELayout object will be created with the correct number of DEs. If a DELayout object is specified its number of DEs must match the number indicated by `regDecompPTile`.

**[vm]** Optional `ESMF_VM` object of the current context. Providing the VM of the current context will lower the method’s overhead.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

### 34.6.9 ESMF_DistGridCreate - Create 1D DistGrid object from user’s arbitrary index list

**INTERFACE:**

```plaintext
! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateDBAI1D(arbSeqIndexList, rc)
```

**RETURN VALUE:**

```plaintext
type(ESMF_DistGrid) :: ESMF_DistGridCreateDBAI1D
```

**ARGUMENTS:**

```plaintext
integer, intent(in) :: arbSeqIndexList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Create an `ESMF_DistGrid` of `dimCount` 1 from a PET-local list of sequence indices. The PET-local size of the `arbSeqIndexList` argument determines the number of local elements in the created DistGrid. The sequence indices must be unique across all PETs. A default DELayout with 1 DE per PET across all PETs of the current VM is automatically created.

The arguments are:

**[arbSeqIndexList]** List of arbitrary sequence indices that reside on the local PET.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.
34.6.10  ESMF_DistGridCreate - Create (1+n)D DistGrid object from user's arbitrary index list and minIndexPTile/maxIndexPTile

INTERFACE:

! Private name; call using ESMF_DistGridCreate()
function ESMF_DistGridCreateDBAI(arbSeqIndexList, arbDim, &
     minIndexPTile, maxIndexPTile, rc)

RETURN VALUE:

    type(ESMF_DistGrid) :: ESMF_DistGridCreateDBAI

ARGUMENTS:

    integer, intent(in) :: arbSeqIndexList(:)
    integer, intent(in) :: arbDim
    integer, intent(in) :: minIndexPTile(:)
    integer, intent(in) :: maxIndexPTile(:)
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DistGrid of dimCount 1 + n, where n = size(minIndexPTile) = size(maxIndexPTile).

The resulting DistGrid will have a 1D distribution determined by the PET-local arbSeqIndexList. The PET-local size of the arbSeqIndexList argument determines the number of local elements along the arbitrarily distributed dimension in the created DistGrid. The sequence indices must be unique across all PETs. The associated, automatically created DELayout will have 1 DE per PET across all PETs of the current VM.

In addition to the arbitrarily distributed dimension, regular DistGrid dimensions can be specified in minIndexPTile and maxIndexPTile. The n dimensional subspace spanned by the regular dimensions is "multiplied" with the arbitrary dimension on each DE, to form a 1 + n dimensional total index space described by the DistGrid object. The arbDim argument allows to specify which dimension in the resulting DistGrid corresponds to the arbitrarily distributed one.

The arguments are:

arbSeqIndexList  List of arbitrary sequence indices that reside on the local PET.

arbDim  Dimension of the arbitrary distribution.

minIndexPTile  Global coordinate tuple of the lower corner of the tile. The arbitrary dimension is not included in this tile.
maxIndexPTile  Global coordinate tuple of the upper corner of the tile. The arbitrary dimension is not included in this tile.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

34.6.11  ESMF_DistGridDestroy - Release resources associated with a DistGrid

INTERFACE:

subroutine ESMF_DistGridDestroy(distgrid, rc)

ARGUMENTS:

type(ESMF_DistGrid), intent(inout) :: distgrid
--- The following arguments require argument keyword syntax (e.g. rc=rc). ---
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroys an ESMF_DistGrid, releasing the resources associated with the object.

The arguments are:

distgrid  ESMF_DistGrid object to be destroyed.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

34.6.12  ESMF_DistGridGet - Get object-wide DistGrid information

INTERFACE:

! Private name; call using ESMF_DistGridGet()
subroutine ESMF_DistGridGetDefault(distgrid, delayout, dimCount, &
tileCount, minIndexPTile, maxIndexPTile, elementCountPTile, &,
minIndexPDe, maxIndexPDe, elementCountPDe, deToTileMap, &,
indexCountPDe, collocation, regDecompFlag, rc)

ARGUMENTS:
type (ESMF_DistGrid), intent(in) :: distgrid

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type (ESMF_DELayout), intent(out), optional :: delayout
integer, intent(out), optional :: dimCount
integer, intent(out), optional :: tileCount
integer, target, intent(out), optional :: minIndexPTile(:,:,)
integer, target, intent(out), optional :: maxIndexPTile(:,:,)
integer, target, intent(out), optional :: elementCountPTile(:)
integer, target, intent(out), optional :: minIndexPDe(:,:,)
integer, target, intent(out), optional :: maxIndexPDe(:,:,)
integer, target, intent(out), optional :: elementCountPDe(:)
integer, target, intent(out), optional :: deToTileMap(:)
integer, target, intent(out), optional :: indexCountPDe(:,:,)
logical, intent(out), optional :: collocation(:)
integer, intent(out), optional :: regDecompFlag
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get internal DistGrid information.

The arguments are:

distgrid  Queried ESMF_DistGrid object.

[delayout] ESMF_DELayout object associated with distgrid.

[dimCount] Number of dimensions (rank) of distgrid.

[tileCount] Number of tiles in distgrid.

[minIndexPTile] Lower index space corner per dim, per tile, with size(minIndexPTile) == (/dimCount, tileCount/).

[maxIndexPTile] Upper index space corner per dim, per tile, with size(minIndexPTile) == (/dimCount, tileCount/).

[elementCountPTile] Number of elements in exclusive region per tile, with size(elementCountPTile) == (/tileCount/)

[minIndexPDe] Lower index space corner per dim, per De, with size(minIndexPDe) == (/dimCount, deCount/).

[maxIndexPDe] Upper index space corner per dim, per de, with size(minIndexPDe) == (/dimCount, deCount/).

[elementCountPDe] Number of elements in exclusive region per DE, with size(elementCountPDe) == (/deCount/)

[deToTileMap] List of tile id numbers, one for each DE, with size(deToTileMap) == (/deCount/)

756
[indexCountPDe] Array of extents per dim, per de, with size(indexCountPDe) == (/dimCount, deCount/).

[collocation] List of collocation id numbers, one for each dim, with size(collocation) == (/dimCount/)

[regDecompFlag] Flag equal to ESMF_TRUE for regular decompositions and equal to ESMF_FALSE otherwise.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

34.6.13 ESMF_DistGridGet - Get DE-local DistGrid information

INTERFACE:

! Private name; call using ESMF_DistGridGet()
subroutine ESMF_DistGridGetPLocalDe(distgrid, localDe, &
    collocation, arbSeqIndexFlag, seqIndexList, elementCount, rc)

ARGUMENTS:

    type(ESMF_DistGrid), intent(in) :: distgrid
    integer, intent(in) :: localDe
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: collocation
    logical, intent(out), optional :: arbSeqIndexFlag
    integer, target, intent(out), optional :: seqIndexList(:)
    integer, intent(out), optional :: elementCount
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get internal DistGrid information.

The arguments are:

distgrid Queried ESMF_DistGrid object.
localDe Local DE for which information is requested. [0,..,localDeCount-1]
[collocation] Collocation for which information is requested. Default to first collocation in collocationPDim list.
[arbSeqIndexFlag] Indicates whether collocation is associated with arbitrary sequence indices.
[seqIndexList] List of sequence indices for the elements on localDe, with size(seqIndexList) == (/elementCountPDe(localDeToDeMap(localDe))/).
34.6.14 ESMF_DistGridGet - Get DE-local DistGrid information for a specific dimension

INTERFACE:

! Private name; call using ESMF_DistGridGet()
subroutine ESMF_DistGridGetPLocalDePDim(distgrid, localDe, dim, &
indexList, rc)

ARGUMENTS:

type(ESMF_DistGrid), intent(in) :: distgrid
integer, intent(in) :: localDe
integer, intent(in) :: dim
integer, target, intent(out) :: indexList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get internal DistGrid information.

The arguments are:

distgrid Queried ESMF_DistGrid object.
localDe Local DE for which information is requested. [0,..,localDeCount-1]
dim Dimension for which information is requested. [1,..,dimCount]
indexList Upon return this holds the list of DistGrid tile-local indices for localDe along dimension dim. The supplied variable must be at least of size indexCountPDimPDe(dim, localDeToDeMap(localDe)).
rc Return code; equals ESMF_SUCCESS if there are no errors.
34.6.15  ESMF_DistGridMatch - Check if two DistGrid objects match

INTERFACE:

    function ESMF_DistGridMatch(distgrid1, distgrid2, rc)

RETURN VALUE:

    type(ESMF_DistGridMatch_Flag) :: ESMF_DistGridMatch

ARGUMENTS:

    type(ESMF_DistGrid), intent(in) :: distgrid1
    type(ESMF_DistGrid), intent(in) :: distgrid2
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

DESCRIPTION:

Determine to which level distgrid1 and distgrid2 match.
Returns a range of values of type ESMF_DistGridMatch_Flag.indicating how closely the DistGrids match. For a description of the possible return values, see 34.2.1. Note that this call only performs PET local matching. Different return values may be returned on different PETs for the same DistGrid pair.

The arguments are:

distgrid1  ESMF_DistGrid object.
distgrid2  ESMF_DistGrid object.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

34.6.16  ESMF_DistGridPrint - Print DistGrid information

INTERFACE:

    subroutine ESMF_DistGridPrint(distgrid, rc)

ARGUMENTS:

    type(ESMF_DistGrid), intent(in) :: distgrid
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Prints internal information about the specified `ESMF_DistGrid` object to stdout.

The arguments are:

- **distgrid**  Specified `ESMF_DistGrid` object.
- **[rc]**  Return code; equals `ESMF_SUCCESS` if there are no errors.

### 34.6.17 ESMF_DistGridValidate - Validate DistGrid internals

**INTERFACE:**

```
subroutine ESMF_DistGridValidate(distgrid, rc)
```

**ARGUMENTS:**

```
type(ESMF_DistGrid), intent(in) :: distgrid
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Validates that the `distgrid` is internally consistent. The method returns an error code if problems are found.

The arguments are:

- **distgrid**  Specified `ESMF_DistGrid` object.
- **[rc]**  Return code; equals `ESMF_SUCCESS` if there are no errors.

### 34.7 Class API: DistGridConnection Methods

#### 34.7.1 ESMF_DistGridConnectionSet - Set DistGridConnection

**INTERFACE:**
subroutine ESMF_DistGridConnectionSet(connection, tileIndexA, tileIndexB, &
positionVector, orientationVector, rc)

ARGUMENTS:

  type(ESMF_DistGridConnection), intent(out) :: connection
  integer, intent(in) :: tileIndexA
  integer, intent(in) :: tileIndexB
  integer, intent(in) :: positionVector(:)
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: orientationVector(:)
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Set an ESMF_DistGridConnection object to represent a connection according to the provided index space information.

The arguments are:

connection  DistGridConnection object.
tileIndexA  Index of one of the two tiles that are to be connected.
tileIndexB  Index of one of the two tiles that are to be connected.
positionVector  Position of tile B's minIndex with respect to tile A's minIndex.
[orientationVector]  Associates each dimension of tile A with a dimension in tile B's index space. Negative index values may be used to indicate a reversal in index orientation. It is erroneous to associate multiple dimensions of tile A with the same index in tile B. By default orientationVector = (/1, 2, 3, .../), i.e. same orientation as tile A.
 [rc]  Return code; equals ESMF_SUCCESS if there are no errors.

35 RouteHandle Class

35.1 Description

The ESMF RouteHandle class provides a unified interface for all route-based communication methods across the Field, FieldBundle, Array, and ArrayBundle classes. All route-based communication methods implement a pre-computation step, returning a RouteHandle, an execution step, and a release step. Typically the pre-computation, or Store() step will be a lot more expensive (both in memory and time) than the execution step. The idea is that once precomputed, a RouteHandle will be executed many times over during a model run, making the execution time a very performance critical piece of code. In ESMF, Regridding, Redisting, and Haloing are implemented as route-based communication methods. The following sections discuss the RouteHandle concepts that apply uniformly to all route-based communication methods, across all of the above mentioned classes.
35.2 Use and Examples

The user interacts with the RouteHandle class through the route-based communication methods of Field, FieldBundle, Array, and ArrayBundle. The usage of these methods are described in detail under their respective class documentation section. The following examples focus on the RouteHandle aspects common across classes and methods.

35.2.1 Bit-for-bit reproducibility

Bit-for-bit (bfb) reproducibility is at the core of the regression testing schemes of many scientific model codes. The bfb requirement makes it possible to easily compare the numerical results of simulation runs using standard binary diff tools.

While bfb reproducibility is desirable (and often required) for regression testing, it does, at the same, limit the available performance optimization opportunities. Especially in highly parallelized code, best performance is often achieved by allowing operations to occur in a flexible order. Under some conditions, however, a change in the order of numerical operations leads to small numerical differences in the results, breaking bfb reproducibility.

ESMF provides the following three levels of bfb reproducibility support, with the associated performance optimization implications:

- Strict bit-for-bit reproducibility: Results are guaranteed to be bit-for-bit identical even when executing across different numbers of PETs. The optimization options are limited to memory layout and message aggregation.
- Relaxed bit-for-bit reproducibility: Results are only guaranteed to be bit-for-bit identical when running across an unchanged number of PETs. The optimization options include partial sums, allowing computational load to be balanced between source and destination PETs, and message sizes to be reduced.
- No guarantee for bit-for-bit reproducibility: Results may differ by numerical round-off. The optimization options include dynamic out-of-order summation of partial sums.

The following discussion uses very simple numerical examples to demonstrate how the order of terms in a sum can lead to results that are not bit-for-bit identical. The examples use single precision, ESMF_KIND_R4 numbers, but the concepts apply the same to double precision, ESMF_KIND_R8; only that the decimals, for which bfb differences in the sums occur, are different ones.

With sumA, sumB, sumC, sumD, and sumE all of type real(ESMF_KIND_R4), one finds the following bfb differences:

\[
\begin{align*}
\text{sumA} &= (0.5 + 0.1) + 0.1 \quad \text{! results in 0.700000048} \\
\text{sumB} &= 0.5 + (0.1 + 0.1) \quad \text{! results in 0.699999988} \\
\text{sumC} &= 0.5 + 0.2 + 0.1 + 0.1 \quad \text{! results in 0.900000036} \\
\text{sumD} &= 0.5 + (0.2 + 0.1) + 0.1 \quad \text{! results in 0.900000036} \\
\text{sumE} &= 0.5 + (0.2 + 0.1 + 0.1) \quad \text{! results in 0.899999976}
\end{align*}
\]

These differences result from the fact that many decimals (even very simple ones like 0.1 or 0.2) lead to periodic binary floating point numbers. Periodic floating point numbers must be truncated when represented by a finite number of bits, leading to small rounding errors. Further truncation occurs when the radix point of two numbers must be aligned during floating point arithmetic, resulting in bit shifts for one of the numbers. The resulting truncation error depends on the precise numbers that need alignment. As a result, executing the "same" sum in a different order can lead to different truncation steps and consequently in results that are not bit-for-bit identical.
In order to help users with the implementation of their bfb requirement, ESMF provides different levels of control over the term order in sparse matrix multiplications, while at the same time offering performance optimization options. In all there are three arguments that will be introduced in the following paragraphs: srcTermProcessing, termorderflag, and pipelineDepth.

For the purpose of demonstration, a one-dimensional, arbitrarily distributed source Array is constructed. There are three Array elements on each of the four PETs. Their local storage indices, sequence indices, and data values are as follows:

<table>
<thead>
<tr>
<th>PET</th>
<th>index</th>
<th>sequence index</th>
<th>data value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0.5</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
<td>6</td>
<td>0.1</td>
</tr>
<tr>
<td>0</td>
<td>3</td>
<td>9</td>
<td>0.1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>4</td>
<td>0.5</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>0.1</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>10</td>
<td>0.1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>11</td>
<td>0.5</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>7</td>
<td>0.1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>5</td>
<td>0.1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>8</td>
<td>0.1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>2</td>
<td>0.2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>12</td>
<td>0.1</td>
</tr>
</tbody>
</table>

The destination Array consists of only a single element, located on PET 0:

<table>
<thead>
<tr>
<th>PET</th>
<th>index</th>
<th>sequence index</th>
<th>data value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>n/a</td>
</tr>
</tbody>
</table>

As a first example consider the following sparse matrix with three entries:

```
factorIndexList(1,1) = 1 ! src seq index
factorIndexList(2,1) = 1 ! dst seq index
factorList(1) = 1.
factorIndexList(1,2) = 6 ! src seq index
factorIndexList(2,2) = 1 ! dst seq index
factorList(2) = 1.
factorIndexList(1,3) = 9 ! src seq index
factorIndexList(2,3) = 1 ! dst seq index
factorList(3) = 1.
```
In ESMF, the order in which the sparse matrix entries are specified in factorIndexList and factorList, or on which PET they are provided, is completely irrelevant. The term order in the resulting sparse matrix sums is not affected by it.

There is one aspect of the sparse matrix format, however, that is relevant to the bfb considerations: When multiple entries for the same (src, dst) pair are present in a sparse matrix definition, the entries are summed into a single (src, dst) entry. Therefore, even if there are multiple sparse matrix entries for the same (src, dst) pair, there will only be a single term for it in the resulting expression.

Going back to the three term sparse matrix definition above, the canonical term order is defined by the source sequence indices in ascending order. With \((src,dst)\) denoting the sparse matrix factors, and \(s(src)\) and \(d(dst)\) denoting source and destination Array elements, respectively, for \(src\) and \(dst\) sequence indices, the sum in canonical order is:

\[
d(1) = (1,1)^*s(1) + (6,1)^*s(6) + (9,1)^*s(9)
\]

For simplicity, the factors in all of the examples are set to 1.0, allowing us to drop them in the expressions. This helps focus on the critical issue – term order:

\[
d(1) = s(1) + s(6) + s(9)
\]

There are two parameters that affect term order in the ESMF sparse matrix multiplication (SMM), and therefore must be considered in the context of bfb reproducibility. First there is the srcTermProcessing parameter which controls grouping of source terms located on the same PET. The value of the srcTermProcessing parameter indicates the maximum number of terms that may be grouped into partial sums on the source PET. Setting srcTermProcessing to 1 means that no partial sums are formed on the source side, however, the source terms are multiplied with their respective sparse matrix factor before being sent to the destination PET. Setting srcTermProcessing to 0 prevents these products from being carried out on the source side, and the source Array elements are sent unmodified. Depending on the distribution of the source Array, values greater than 1 for srcTermProcessing can lead to partial sums and thus may have impact on the bfb reproducibility of the SMM.

The second parameter that may have bfb effects comes into play at execution-time of a precomputed RouteHandle. It is accessible via the termorderflag argument; a typed flag with the following values:

- **ESMF_TERMORDER_SRCSEQ** – Strictly enforces the canonical order of the source terms according to the source sequence index. However, terms that are grouped together in the RouteHandle at store-time, as a consequence of srcTermProcessing, are treated as single entities with a sequence index equal to the lowest original sequence index in the group. Use ESMF_TERMORDER_SRCSEQ together with srcTermProcessing=0 or srcTermProcessing=1 when strict bfb reproducibility is required independent of the source Array distribution, e.g. for different number of PETs.

- **ESMF_TERMORDER_SRCPET** – The source terms in the sum are first arranged according to the relative position of the PET on which they reside with respect to the destination PET. Second, all the terms coming from the same PET are sorted in canonical sequence index order and summed into partial sums. Again, terms that are grouped together in the RouteHandle at store-time are treated as single entities with a sequence index equal to the lowest original sequence index in the group. The final result for each destination element is determined by adding the partial sums in an order that is fixed by the position of the partial sums’ source PETs relative to the destination PET. This ensures bfb reproducibility of the result as long as the number of PETs remains unchanged.

- **ESMF_TERMORDER_FREE** – For this option there are no restrictions on the term order. Terms can be summed in any order, and the order may change each time the RouteHandle is executed. This option grants greatest flexibility to the RouteHandle execution implementation. It is available for all the methods that take the termorderflag argument. Without a guaranteed source term order, the ESMF_TERMORDER_FREE option is not suitable for situations that require bfb reproducibility.

**ESMF_TERMORDER_SRCSEQ**

First using srcTermProcessing=0 at store time and termorderflag=ESMF_TERMORDER_SRCSEQ at execution time, the canonical term order is expected:

\[
d(1) = s(1) + s(6) + s(9) = 0.5 + 0.1 + 0.1 = \text{sumA}
\]
! forced srcTermProcessing
srcTermProcessing = 0

call ESMF_ArraySMMStore(srcArray, dstArray, &
  factorIndexList=factorIndexList, factorList=factorList, &
  routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
  termorderflag=ESMF_TERMORDER_SRCSEQ, rc=rc)

if (localPet == 0) then
  print *, "result SRCSEQ#1 = ", farrayPtr(1), " expect: ", sumA
  if (farrayPtr(1) /= sumA) &
    finalrc = ESMF_FAILURE
endif

The order of source terms across PETs is expected to have no effect on the bfb reproducibility of the result for ESMF_TERMORDER_SRCSEQ. To test this, a sparse matrix is used where the source terms originate from different PETs.

  factorIndexList(1,1) = 4 ! src seq index
  factorIndexList(2,1) = 1 ! dst seq index
  factorList(1) = 1.
  factorIndexList(1,2) = 5 ! src seq index
  factorIndexList(2,2) = 1 ! dst seq index
  factorList(2) = 1.
  factorIndexList(1,3) = 12 ! src seq index
  factorIndexList(2,3) = 1 ! dst seq index
  factorList(3) = 1.

Again the srcTermProcessing argument is kept at 0, ensuring that none of the source terms are grouped into partial sums.

! forced srcTermProcessing
srcTermProcessing = 0

call ESMF_ArraySMMStore(srcArray, dstArray, &
  factorIndexList=factorIndexList, factorList=factorList, &
  routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
  termorderflag=ESMF TERMORDER SRCSEQ, rc=rc)

Under ESMF_TERMORDER_SRCSEQ it does not matter on which PET a source term is located, the order of source terms is strictly defined by the order of source sequence indices:

d(1) = s(4) + s(5) + s(12) = 0.5 + 0.1 + 0.1 = sumA

765
if (localPet == 0) then
    print *, "result SRCSEQ#2 = ", farrayPtr(1), " expect: ", sumA
    if (farrayPtr(1) /= sumA) &
        finalrc = ESMF_FAILURE
endif

The same sparse matrix leads to bfb differences in the result when executed with the ESMF_TERMORDER_SRCPET option. This is demonstrated further down in result SRCPET#4.

**ESMF_TERMORDER_SRCPET**

All source terms coming from the same PET

In the following examples the srcTermProcessing argument at store-time is first set to 0, forcing all of the source terms to be sent to the destination PET unmodified. We start by going back to the initial sparse matrix where all of the source terms are located on the same PET.

```
    factorIndexList(1,1) = 1 ! src seq index
    factorIndexList(2,1) = 1 ! dst seq index
    factorList(1) = 1.
    factorIndexList(1,2) = 6 ! src seq index
    factorIndexList(2,2) = 1 ! dst seq index
    factorList(2) = 1.
    factorIndexList(1,3) = 9 ! src seq index
    factorIndexList(2,3) = 1 ! dst seq index
    factorList(3) = 1.
```

! forced srcTermProcessing
srcTermProcessing=0

```
call ESMF_ArraySMMStore(srcArray, dstArray, &
    factorIndexList=factorIndexList, factorList=factorList, &
    routehandle=rhs, srcTermProcessing=srcTermProcessing, rc=rc)
```

Then, at execution time, the ESMF_TERMORDER_SRCPET option is used.

```
call ESMF_ArraySMM(srcArray, dstArray, routehandle=rhs, &
    termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)
```

Here all of the source elements originate from the same PET (PET 0). This fact, together with the ESMF_TERMORDER_SRCPET execution-time option, results in the following canonical term order:

```
d(1) = s(1) + s(6) + s(9) = 0.5 + 0.1 + 0.1 = sumA
```

This is exactly the same term order that was used above to produce the result stored in sumA.

```
if (localPet == 0) then
    print *, "result SRCPET#1 = ", farrayPtr(1), " expect: ", sumA
    if (farrayPtr(1) /= sumA) &
        finalrc = ESMF_FAILURE
endif
```
The sequence indices of the source terms are the only relevant aspect in determining the source term order. Consider, for example, the following sparse matrix, where again all source terms are located on the same PET (PET 2):

\[
\begin{array}{c}
\text{factorIndexList}(1,1) = 11 \quad \text{! src seq index} \\
\text{factorIndexList}(2,1) = 1 \quad \text{! dst seq index} \\
\text{factorList}(1) = 1. \\
\text{factorIndexList}(1,2) = 5 \quad \text{! src seq index} \\
\text{factorIndexList}(2,2) = 1 \quad \text{! dst seq index} \\
\text{factorList}(2) = 1. \\
\text{factorIndexList}(1,3) = 7 \quad \text{! src seq index} \\
\text{factorIndexList}(2,3) = 1 \quad \text{! dst seq index} \\
\text{factorList}(3) = 1. \\
\end{array}
\]

This time the source term order in memory is not the same as their sequence index order. Specifically, the sequence indices of the source terms, in the order they are stored in memory, is 11, 7, 5 (see the source Array diagram above for reference). Further, as mentioned already, the order of entries in the sparse matrix also have not bearing on the term order in the SMM sums. Then, for the ESMF_TERMORDER_SRCPET option, and because all source terms are located on the same PET, the resulting source term order is the canonical one determined by the source term sequence indices alone:

\[ d(1) = s(5) + s(7) + s(11) \]

Filling in the source element data, we find

\[ d(1) = 0.1 + 0.1 + 0.5, \]

which is expected to be bfb equivalent to the result stored in \texttt{sumB} from above.

```fortran
! forced srcTermProcessing
srcTermProcessing=0

call ESMF_ArraySMMStore(srcArray, dstArray, &
     factorIndexList=factorIndexList, factorList=factorList, &
     routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
     termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if (localPet == 0) then
    print *, "result SRCPET#2 = ", farrayPtr(1), " expect: ", sumB
    if (farrayPtr(1) /= sumB) &
        finalrc = ESMF_FAILURE
endif
```

Source terms coming from different PETs

When the source terms are distributed across multiple PETs, the ESMF_TERMORDER_SRCPET option first bundles the terms according to the PET on which they are stored. These source term "bundles" are then arranged in an order that depends on the source PET position relative to the destination PET: starting with the bundle for which the source PET is the same as the destination PET, the source term bundles are placed in descending order with respect to their
source PET, modulo petCount. The terms within each source term bundle are further sorted in the canonical order according to their sequence index.

The following sparse matrix demonstrates the effect of the ESMF_TERMORDER_SRCPET option.

```
factorIndexList(1,1) = 1 ! src seq index
factorIndexList(2,1) = 1 ! dst seq index
factorList(1) = 1.
factorIndexList(1,2) = 3 ! src seq index
factorIndexList(2,2) = 1 ! dst seq index
factorList(2) = 1.
factorIndexList(1,3) = 7 ! src seq index
factorIndexList(2,3) = 1 ! dst seq index
factorList(3) = 1.
```

Here the source terms are located on PETs 0, 1, and 2. Using a [] notion to indicate the source PET of each term, the term order under ESMF_TERMORDER_SRCPET is given by:

\[
d(1) = s(1)[0] + s(7)[2] + s(3)[1] = 0.5 + 0.1 + 0.1
\]

This is again the same order of terms that was used to produce the result stored in sumA above.

```
! forced srcTermProcessing
srcTermProcessing=0

call ESMF_ArraySMMStore(srcArray, dstArray, &
    factorIndexList=factorIndexList, factorList=factorList, &
    routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
    termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if (localPet == 0) then
    print *, "result SRCPET#3 = ", farrayPtr(1), " expect: ", sumA
    if (farrayPtr(1) /= sumA) &
        finalrc = ESMF_FAILURE
endif
```

In the above example, the fact that the terms were ordered by source PET first, did not lead to numerical bfb differences compared to the canonical source term order. However, this was purely coincidental in the way the numbers worked out for this example. The following case looks at a situation where the source PET order does lead to a result that shows bfb differences compared to the canonical term order.

```
factorIndexList(1,1) = 4 ! src seq index
factorIndexList(2,1) = 1 ! dst seq index
factorList(1) = 1.
factorIndexList(1,2) = 5 ! src seq index
factorIndexList(2,2) = 1 ! dst seq index
factorList(2) = 1.
factorIndexList(1,3) = 12 ! src seq index
```
The canonical source term order of this SMM sum, determined by the source sequence indices alone, is:
\[ d(1) = s(4) + s(5) + s(12) = 0.5 + 0.1 + 0.1, \]
which again would lead to a result that is bfb identical to \( \text{sumA} \). However, this is not the term order resulting from the `ESMF_TERMORDER_SRCPET` option. The actual order for this option is:
\[ d(1) = s(12)[3] + s(5)[2] + s(4)[1] = 0.1 + 0.1 + 0.5, \]
resulting in a sum that is bfb identical to \( \text{sumB} \) instead.

Grouping of source terms coming from the same PET

So far the `srcTermProcessing` argument was kept at 0, and therefore source term grouping had not to be considered. Source term grouping is only possible for terms that originate from the same PET. In preparation for a closer look at the bfb effects of source term grouping, consider a sparse matrix where two of the source terms are located on PET 0 while the other two source terms are originating on PET 2. Keeping the `srcTermProcessing` argument at 0 first, the term order under `ESMF_TERMORDER_SRCPET` is given by:

\[ d(1) = s(1)[0] + s(5)[2] + s(7)[2] = 0.5 + 0.1 + 0.1 \]

And again the result is expected to be bfb identical to the number stored in \texttt{sumA}.

```
! forced srcTermProcessing
srcTermProcessing=0

call ESMF_ArraySMMStore(srcArray, dstArray, &
   factorIndexList=factorIndexList, factorList=factorList, &
   routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
   termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if (localPet == 0) then
   print *, "result SRCPET#5 = ", farrayPtr(1), " expect: ", sumA
   if (farrayPtr(1) /= sumA) &
      finalrc = ESMF_FAILURE
endif
```

The same result is also expected with \texttt{srcTermProcessing} set to 1. A value of 1 indicates that the multiplication of the source term with its sparse matrix factor is carried out on the source side before being sent to the destination PET. The final sum is still carried out in the same order on the destination PET, essentially resulting in the exact same bfb identical sum as for \texttt{srcTermProcessing} set to 0.

```
! forced srcTermProcessing
srcTermProcessing=1

call ESMF_ArraySMMStore(srcArray, dstArray, &
   factorIndexList=factorIndexList, factorList=factorList, &
   routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
   termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if (localPet == 0) then
   print *, "result SRCPET#6 = ", farrayPtr(1), " expect: ", sumA
   if (farrayPtr(1) /= sumA) &
      finalrc = ESMF_FAILURE
endif
```

Increasing the \texttt{srcTermProcessing} argument to 2 (or higher) results in source term grouping of the terms (up to the number specified in \texttt{srcTermProcessing}) that are on the same source PET.

\[ d(1) = s(1)[0] + ( s(5)[2] + s(7)[2] ) = 0.5 + (0.1 + 0.1) \]

This result is bfb identical to first adding 0.1 and 0.1 into a partial sum, and then adding this sum to 0.5. This is the exact grouping of terms that was used to obtain the result stored in \texttt{sumB} from above.
In order to explore the effects of the `srcTermProcessing` argument further, more terms on the same source PET are needed in the SMM sum. The following sparse matrix has four entries, three of which originate from the same PET (PET 3).

```plaintext
factorIndexList(1,1) = 1 ! src seq index
factorIndexList(2,1) = 1 ! dst seq index
factorList(1) = 1.
factorIndexList(1,2) = 2 ! src seq index
factorIndexList(2,2) = 1 ! dst seq index
factorList(2) = 1.
factorIndexList(1,3) = 8 ! src seq index
factorIndexList(2,3) = 1 ! dst seq index
factorList(3) = 1.
factorIndexList(1,4) = 12 ! src seq index
factorIndexList(2,4) = 1 ! dst seq index
factorList(4) = 1.
```

Setting the `srcTermProcessing` argument back to 0 puts the terms in PET order, and canonical order for each PET bundle.

```plaintext
d(1) = s(1)[0] + s(2)[3] + s(8)[3] + s(12)[3] = 0.5 + 0.2 + 0.1 + 0.1
```

The bfb identical result for this sum was calculated and stored in variable `sumC` above.

```plaintext
! forced srcTermProcessing
srcTermProcessing=0

call ESMF_ArraySMMStore(srcArray, dstArray, &
    factorIndexList=factorIndexList, factorList=factorList, &
    routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
    termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)
```
if (localPet == 0) then
  print *, "result SRCPET#8 = ", farrayPtr(1), " expect: ", sumC
  if (farrayPtr(1) /= sumC) &
      finalrc = ESMF_FAILURE
endif

Setting the srcTermProcessing argument to a value of 2 results in the following source term grouping:
\[ d(1) = s(1)[0] + (s(2)[3] + s(8)[3]) + s(12)[3] = 0.5 + (0.2 + 0.1) + 0.1, \]
where the \((0.2 + 0.1)\) partial sum is carried out on source PET 3, and then sent to the destination PET (PET 0), together with the unmodified data from source element 8 \((0.1)\). The final sum is performed on PET 0. The result is identical to the precomputed value stored in \(\text{sumD}\). The numbers work out in a way where this result is bfb identical to the previous result, i.e. \(\text{sumC}\). However, this bfb match is purely coincidental.

! forced srcTermProcessing
srcTermProcessing=2

call ESMF_ArraySMMStore(srcArray, dstArray, &
  factorIndexList=factorIndexList, factorList=factorList, &
  routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
  termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if (localPet == 0) then
  print *, "result SRCPET#9 = ", farrayPtr(1), " expect: ", sumD
  if (farrayPtr(1) /= sumD) &
      finalrc = ESMF_FAILURE
endif

Increasing the srcTermProcessing argument up to 3 results in a three term partial sum on PET 3:
\[ d(1) = s(1)[0] + (s(2)[3] + s(8)[3] + s(12)[3]) = 0.5 + (0.2 + 0.1 + 0.1), \]
Again the final sum is performed on PET 0. The result is bfb identical to the number stored in \(\text{sumE}\), which, for the chose numbers, works out to have a bfb difference compared to \(\text{sumC}\) and \(\text{sumD}\).

! forced srcTermProcessing
srcTermProcessing=3

call ESMF_ArraySMMStore(srcArray, dstArray, &
  factorIndexList=factorIndexList, factorList=factorList, &
  routehandle=rh, srcTermProcessing=srcTermProcessing, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
  termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)
if (localPet == 0) then
  print *, "result SRCPET#10 = ", farrayPtr(1), " expect: ", sumE
  if (farrayPtr(1) /= sumE) &
    finalrc = ESMF_FAILURE
endif

Reproducibility and Performance

The above examples show how bit-for-bit (bfb) reproducibility is a result of controlling the term order. ESMF offers several options to control the term order in the sparse matrix multiplication (SMM) implementation:

- To guarantee bfb reproducibility between consecutive executions of the same RouteHandle object, the ESMF_TERMORDER_SRCPET execution-time option suffices.
- If bfb reproducibility is required between different RouteHandles, e.g. a RouteHandle that is precomputed each time the application starts, then it must be further ensured that the same value of srcTermProcessing is specified during the store call. Under these conditions the ESMF SMM implementation guarantees bfb identical results between runs, as long as the number of PETs does not change.
- To guarantee bfb reproducibility between different runs, even when the number of PETs, and therefore the data distribution changes, the execution option ESMF_TERMORDER_SRCSEQ must be chosen together with srcTermProcessing equal to 0 or 1 (in order to prevent partial sums).

The term order in a SMM operation does not only affect the bfb reproducibility of the result, but also affects the SMM performance. The precise performance implications of a specific term order are complicated and strongly depend on the exact problem structure, as well as on the details of the compute hardware. ESMF implements an auto-tuning mechanism that can be used to conveniently determine a close to optimal set of SMM performance parameters.

There are two SMM performance parameters in ESMF that are encoded into a RouteHandle during store-time: srcTermProcessing and pipelineDepth. The first one affects the term order in the SMM sums and has been discussed in detail above. The second parameter, pipelineDepth, determines how many in- and out-bound messages may be outstanding on each PET. It has no affect on the term order and does not lead to bfb differences in the SMM results. However, in order to achieve good performance reproducibility, the user has the option to pass in a fixed value of the pipelineDepth argument when precomputing RouteHandles.

Store calls that take the srcTermProcessing and/or pipelineDepth argument specify them as optional with intent (inout). Omitting the argument when calling, or passing a variable that is set to a negative number, indicates that the respective parameter needs to be determined by the library. Further, if a variable with a negative value was passed in, then the variable is overwritten and replaced by the auto-tuned value on return. Through this mechanism a user can leverage the built-in auto-tuning feature of ESMF to obtain the best possible performance for a specific problem on a particular compute hardware, while still ensuring bfb and performance reproducibility between runs. The following example shows code that first checks if previously stored SMM performance parameters are available in a file on disk, and then either reads and uses them, or else uses auto-tuning to determine the parameters before writing them to file. For simplicity the same sparse matrix as in the previous example is used.

    ! precondition the arguments for auto-tuning and overwriting
    srcTermProcessing = -1 ! init negative value
    pipelineDepth = -1 ! init negative value

    ! get a free Fortran i/o unit
    call ESMF_UtilIOUnitGet(unit=iounit, rc=rc)

    ! try to open the file that holds the SMM parameters
open(unit=iounit, file="smmParameters.dat", status="old", action="read", &
 iostat=iostat)

if (iostat == 0) then
  ! the file was present -> read from it and close it again
  read(unit=iounit, iostat=iostat, fmt=*) srcTermProcessing, pipelineDepth, &
        sumCompare
  close(unit=iounit)
endif

if (iostat == 0) then
  print *, "SMM parameters successfully read from file"
endif

call ESMF_ArraySMMStore(srcArray, dstArray, &
        factorIndexList=factorIndexList, factorList=factorList, &
        routehandle=rh, srcTermProcessing=srcTermProcessing, &
        pipelineDepth=pipelineDepth, rc=rc)

call ESMF_ArraySMM(srcArray, dstArray, routehandle=rh, &
        termorderflag=ESMF_TERMORDER_SRCPET, rc=rc)

if ((localPet==0) .and. (iostat /= 0)) then
  print *, "SMM parameters determined via auto-tuning -> dump to file"
  open(unit=iounit, file="smmParameters.dat", status="unknown", &
        action="write")
  write(unit=iounit, fmt=*) srcTermProcessing, pipelineDepth, farrayPtr(1)
  close(unit=iounit)
endif

if (localPet == 0) then
  if (iostat /= 0) then
    ! cannot do bfb comparison of the result without reference
    print *, "result SRCPET#11 = ", farrayPtr(1)
  else
    ! do bfb comparison of the result against reference
    print *, "result SRCPET#11 = ", farrayPtr(1), " expect: ", sumCompare
    if (farrayPtr(1) /= sumCompare) &
       finalrc = ESMF_FAILURE
  endif
endif
endif

Running this example for the first time exercises the auto-tuning branch. The auto-tuned srcTermProcessing and pipelineDepth parameters are then used in the SMM execution, as well as written to file. The SMM result variable is also written to the same file for test purposes. Any subsequent execution of the same example branches into the code that reads the previously determined SMM execution parameters from file, re-using them during store-time. This ensures bfb reproducibility of the SMM result, which is tested in this example by comparing to the previously stored value.
35.3 Restrictions and Future Work

- Non-blocking communication via the routesyncflag option is implemented for Fields and Arrays. It is not yet available for FieldBundles and ArrayBundles.

35.4 Design and Implementation Notes

Internally all route-based communication calls are implemented as sparse matrix multiplications. The precompute step for all of the supported communication methods can be break into three steps:

1. Construction of the sparse matrix for the specific communication method.
2. Generation of the communication pattern according to the sparse matrix.
3. Encoding of the communication pattern for each participating PET in form of an XXE stream.

35.5 Class API

35.5.1 ESMF_RouteHandlePrint - Print the contents of a RouteHandle

INTERFACE:

    subroutine ESMF_RouteHandlePrint(rhandle, rc)

ARGUMENTS:

    type(ESMF_RouteHandle), intent(in) :: rhandle
    integer, intent(out), optional :: rc

DESCRIPTION:

Print information about an ESMF_RouteHandle.

The arguments are:

rhandle ESMF_RouteHandle to print contents of.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
36 IO Capability

36.1 Description

The ESMF IO provides an unified interface for input and output of high level ESMF objects such as Fields. In the current release, the ESMF IO capability is integrated with third-party software such as [Parallel IO (PIO)] to read and write Fortran array data in MPI_IO binary or NetCDF format, and [Xerces Library] to read Attribute data in XML format. Other file IO functionalities, such as writing of error and log messages, input of configuration parameters from an ASCII file, and lower-level IO utilities are covered in different sections of this document. See the Log Class [46.1], the Config Class [45.1], and the Fortran I/O Utilities [49.1] respectively.

36.2 Attribute I/O

Metadata IO is handled via the ESMF Attribute class. The third party software Xerces C++ Library is used by ESMF to provide the ability to read Attribute data in XML file format. To enable this capability, the environment variable ESMF_XERCES must be set. Details can be found in the ESMF User Guide, "Building and Installing the ESMF", "Third Party Libraries". Writing Attribute XML files is performed with the standard C++ output file stream facility.

In the current release, the following methods support Attribute XML I/O using Xerces:

ESMF_AttributeRead(), section [38.11.35]

36.3 Data I/O

ESMF provides interfaces for high performance, parallel I/O using ESMF data objects such as Arrays and Fields. Currently ESMF supports I/O of binary and NetCDF files. The current ESMF implementation relies on the [Parallel IO (PIO)] library developed as a collaboration between NCAR and DOE laboratories. PIO is built as part of the ESMF build when the environment variable ESMFPIO is set to "internal"; by default it is not set. When PIO is built with ESMF, the ESMF methods internally call the PIO interfaces. When PIO is not built with ESMF, the ESMF methods are non-operable (no-op) stubs that simply return with a return code of ESMF_RC_LIB_NOT_PRESENT. Details about the environment variables can be found in ESMF User Guide, "Building and Installing the ESMF", "Third Party Libraries".

In the current release, the following methods support parallel data I/O using PIO:

ESMF_FieldBundleRead(), section [24.5.15]
ESMF_FieldBundleWrite(), section [24.5.34]
ESMF_FieldRead(), section [25.6.51]
ESMF_FieldWrite(), section [25.6.67]
ESMF_ArrayBundleRead(), section [26.5.15]
ESMF_ArrayBundleWrite(), section [26.5.26]
ESMF_ArrayRead(), section [27.5.25]
ESMF_ArrayWrite(), section [27.5.38]
36.4 Data formats

Two formats are supported, namely, NetCDF and binary (through MPI_IO). The environment variables that are enabled when ESMF is built determine the format. The environment variables ESMF_NETCDF or/and ESMF_PNETCDF should be set to "standard" to enable NetCDF IO format. If neither ESMF_NETCDF nor ESMF_PNETCDF are set, and MPI_IO is enabled in MPI, the format will be binary. Details about the environment variables can be found in ESMF User Guide, "Building and Installing the ESMF", "Third Party Libraries".

NetCDF  Network Common Data Form (NetCDF) is an interface for array-oriented data access. The NetCDF library provides an implementation of the interface. It also defines a machine-independent format for representing scientific data. Together, the interface, library, and format support the creation, access, and sharing of scientific data. The NetCDF software was developed at the Unidata Program Center in Boulder, Colorado. See [21]. In geoscience, NetCDF can be naturally used for representation of fields defined on logically rectangular grids. NetCDF use in geosciences is specified by CF conventions mentioned above [20].

To the extent that data on unstructured grids (or even observations) can be represented as one-dimensional arrays, NetCDF can also be used to store these data. However, it does not provide a high-level abstraction for this type of data.

IEEE Binary Streams  A natural way for a machine to represent data is to use a native binary data representation. There are two choices of ordering of bytes (so-called Big Endian and Little Endian), and a lot of ambiguity in representing floating point data. The latter, however, is specified, if IEEE Floating Point Standard 754 is satisfied. ([12], [17], [10]).

36.5 Restrictions and Future Work

Currently, a small fraction of the anticipated data formats is implemented by ESMF. The data IO uses NetCDF and MPI_IO binary formats, and ESMF Attribute IO uses XML format. Different libraries are employed for these different formats. In future development, a more centralized IO technique will likely be defined to provide efficient utilities with a set of standard APIs that will allow manipulation of multiple standard formats. Also, the ability to automatically detect file formats at runtime will be developed.

36.6 Design and Implementation Notes

For data IO, the ESMF IO capability relies on the PIO, NetCDF, PNetCDF, and MPI_IO libraries. For Attribute IO, the ESMF IO capability uses the Xerces library to perform reading of XML files. PIO is included with the ESMF distribution; the other libraries must be installed on the machine of interest.
Part V

Infrastructure: Utilities
Overview of Infrastructure Utility Classes

The ESMF utilities are a set of tools for quickly assembling modeling applications.

The ESMF Attribute class enables models to be self-describing via metadata, which are instances of Attribute name-value pairs.

The Time Management Library provides utilities for time and time interval representation and calculation, and higher-level utilities that control model time stepping, via clocks, as well as alarming.

The ESMF Config class provides configuration management based on NASA DAO’s Inpak package, a collection of methods for accessing files containing input parameters stored in an ASCII format.

The ESMF LogErr class consists of a variety of methods for writing error, warning, and informational messages to log files. A default Log is created during ESMF initialization. Other Logs can be created later in the code by the user.

The DELayout class provides a layer of abstraction on top of the Virtual Machine (VM) layer. DELayout does this by introducing DEs (Decomposition Elements) as logical resource units. The DELayout object keeps track of the relationship between its DEs and the resources of the associated VM object. A DELayout can be shaped by the user at creation time to best match the computational problem or other design criteria.

The ESMF VM (Virtual Machine) class is a generic representation of hardware and system software resources. There is exactly one VM object per ESMF Component, providing the execution environment for the Component code. The VM class handles all resource management tasks for the Component class and provides a description of the underlying configuration of the compute resources used by a Component. In addition to resource description and management, the VM class offers the lowest level of ESMF communication methods.

The ESMF Fortran I/O utilities provide portable methods to access capabilities which are often implemented in different ways amongst different environments. Currently, two utility methods are implemented: one to find an unopened unit number, and one to flush an I/O buffer.
38 Attribute Class

38.1 Description

The ESMF Attribute class is a metadata utility that supports emerging standards in a flexible way. The Attribute class is useful for documenting data provenance and encourages models to be more self describing. Attributes can also be used to automate some aspects of model execution and coupling.

Metadata, which is data about data, is broken down into name-value pairs by the Attribute class. Attributes can be attached at any level of the ESMF object hierarchy, and in some cases the Attributes of different ESMF objects can be linked together to form a corresponding Attribute hierarchy. Attribute hierarchies are linked up automatically for the most part, with the exception of links between Components and between a Component and a State. Attribute hierarchies can also be unlinked, copied, and moved around as needed.

ESMF Attribute packages are used to aggregate, store, and output model metadata. They can be nested inside each other to make larger organized packages, distributed across processors and updated at runtime, and expanded to suit specific needs. The ESMF-supplied Attribute packages are designed around accepted metadata conventions, such as: climate and forecast (CF), ISO standards, and the METAFORE Common Information Model (CIM).

Most of the ESMF deep objects can host Attributes, and every object that can hold individual Attributes can also hold Attribute packages. Attribute hierarchies are supported for a majority of the Attribute bearing classes. More information on the various Attribute capabilities, and the classes for which they are supported appear in the following sections.

Reading Attribute XML files requires the Xerces C++ library, v3.1.0 or better. For more details, see the "ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, Xerces". Writing Attribute XML files is performed with the standard C++ output file stream facility.

38.1.1 Schemas and Controlled Vocabularies

There are two pieces to the information stored in Attributes. One piece is the property name and type, and its relation to other properties; this is the schema. The other piece is the range of values that are valid for a particular property; this is the controlled vocabulary. For many information models, including the Common Information Model (CIM), these two pieces are managed and versioned separately.

ESMF implements the appropriate schema internally; it translates the Attributes as specified in the Attribute packages into the correct format based on the convention and purpose as specified in arguments to most Attribute functions. The controlled vocabularies, or Attribute values, however, are not controlled or validated within ESMF.

38.1.2 The Common Information Model (CIM)

The CIM is a formal model of the climate modeling process being developed by the European Union’s METAFORE project. The Earth System - Documentation (ES-DOC) project is an evolution of the METAFORE project, and they provide a detailed description of the CIM.

ESMF is currently implementing only a subset of version 1.5 of the CIM, though this representation is expected to grow.

Mapping Attributes to the CIM

The ESMF Attribute packages provide a structure for the Attributes that are useful for climate modelers. When the ESMF_AttributeWrite() function is called with "CIM" XML specified as the target, ESMF translates these
package structures into a format defined by the CIM schema. The package descriptions in the following sections provide a mapping from the ESMF Attribute name to the CIM schema field.

For example, in the CIM Main Attribute Package, the Attribute named "LongName" is mapped to the CIM schema field, "software:SoftwareComponent:longName":

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>LongName</td>
<td>A version of the component name with all acronyms spelled out.</td>
<td>N/A</td>
<td>software:SoftwareComponent:longName</td>
</tr>
</tbody>
</table>

There are 3 parts to this mapping:

- `<CIM section>` = "software"
- `<Entity>` = "SoftwareComponent"
- `<Field>` = "longName"

The CIM section refers to the categories, or subsections, of the CIM mentioned above. In this example, the CIM section is "software". To find this section in the CIM schema repository, go to the [CIM repository](#) and then select the "software" drop down (see Figure 21).
Figure 21: The software section of the CIM repository
You can view the schema graphically in a UML diagram by selecting the software.png file and then visually search the picture for the SoftwareComponent entity. However, this view does not provide field details, such as type and description. Alternatively, you can select the software.xsd file, and then search the XML for the entity, "SoftwareComponent," and the field, "longName," which will provide the details for this field (see Figure 22).

```xml
<xs:complexType>
  <xs:complexType xmlns:xs="http://www.w3.org/2001/XMLSchema" name="SoftwareComponent"
      abstract="true">
    <xs:annotation>
      <xs:documentation>
        A SoftwareComponent is an abstract component from which all other components and generates output data. A SoftwareComponent can include nested "child" components. Every component has scientific properties that a component simulates (for example, temperature, pressure, etc.) and performs its simulation (for example, the force of gravity). A SoftwareComponent can also have computing resources. And a SoftwareComponent can have a composition, which describes how ComposableSoftwareComponents or external data files. The properties specified by a component's composition component; child components cannot couple together their parents' properties.</xs:documentation>
    </xs:annotation>
    <xs:complexContent>
      <xs:extension base="DataSource">
        <xs:sequence>
          <xs:element name="shortName" minOccurs="1" maxOccurs="1" type="xs:string">
            <xs:annotation>
              <xs:documentation>The name of the model (that is used internally).</xs:documentation>
            </xs:annotation>
          </xs:element>
          <xs:element name="longName" minOccurs="0" maxOccurs="1" type="xs:string">
            <xs:annotation>
              <xs:documentation>The name of the model (that is recognized externally).</xs:documentation>
            </xs:annotation>
          </xs:element>
          <xs:element name="description" minOccurs="0" maxOccurs="1" type="xs:string">
            <xs:annotation>
            </xs:annotation>
          </xs:element>
        </xs:sequence>
      </xs:extension>
    </xs:complexContent>
  </xs:complexType>
</xs:complexType>
```

Figure 22: The longName Field in the CIM software XSD file
As the ES-DOC team continues its work, more tools will be provided to support CIM implementations. Currently, a more user-friendly way to view the CIM schema is available [here](#).

### 38.1.3 The ESMF approach to Attributes

ESMF’s approach to Attributes can be summarized as follows:

- Implement community standards where they exist.
- Associate Attributes with the ESMF object they describe. Currently, the following ESMF objects can have Attributes:
  - CplComp
  - GridComp
  - State
  - FieldBundle
  - Field
  - ArrayBundle
  - Array
  - Grid
  - DistGrid
- Establish pre-defined Attribute packages (see Section 38.2) to make Attribute creation easier for the user.
- Allow for user-defined custom Attribute packages (see Section 38.2.7).
- Enable the nesting of Attribute packages (see Section 38.3) including Custom packages.
- Enable complex Attribute hierarchies (see Section 38.1.4).
- Export Attributes in more than one format (see Section 38.4).
- Ensure that all Attributes are consistent across the entire virtual machine of the object to which they are attached.

### 38.1.4 Attribute hierarchies

Of the ESMF objects with Attributes, only some can link their Attributes together in an Attribute hierarchy. These objects are:

- CplComp
- GridComp
- State
- FieldBundle
- Field
- ArrayBundle
Array

Every ESMF deep object is given a root Attribute on creation. These root Attributes serve as the attachment point for all metadata that is stored on a particular ESMF object, including all Attributes and Attribute packages. The root Attributes can also be connected together via the ESMF_AttributeLink() functionality. This happens automatically in most cases, such as when a Field is added to a FieldBundle, and results in the formation of an Attribute hierarchy which mirrors the structure of the underlying object hierarchy.

When two Attribute hierarchies are linked together the objects are given read-only access to each other’s Attributes. To ensure consistency across a distributed system, there can only ever be one set of Attributes associated with each ESMF object. This implies that a copy operation on an ESMF object Attribute hierarchy can use a value copy for all Attributes which are owned by the object being copied, but must use a reference copy for all Attributes which the object can access (through links) but does NOT own. See section 38.9.6 for more details on this concept.

The most common use for this hierarchy capability is for linking the Attributes of a Field to the FieldBundle which holds it, which is then linked to the State that is used to transport all of the data for a Component. All of these links, with the exception of the link between the Component and the State, are automatically handled by ESMF. Additionally, the State will automatically set a VariableIntent Attribute for Field when that Field is added to the State. VariableIntent will be set to either Export or Import.

38.2 Attribute Packages

At this time, all ESMF objects which are enabled to contain Attributes can also contain Attribute packages, which are groupings of individual Attributes. Every Attribute package is specified by a convention and a purpose, such as "CF" and "General" (see below), as arguments to many of the Attribute functions. These are used to validate ESMF Attribute packages against existing metadata conventions. The user can choose to use an ESMF pre-defined Attribute package, specify their own Attribute package, or add customized Attributes to any of the ESMF pre-defined Attribute packages. Currently, the creation and setting of Attribute packages is quite involved, but future development with IO will allow for a more automated approach to populating Attribute packages from a file. This is already possible via ESMF_AttributeRead() for the ESMF/CF Attribute packages supplied by ESMF, as well as for custom individual Attributes not in a package.

The standard Attribute packages supplied by ESMF exist for the following ESMF objects:

- CplComp
- GridComp
- State
- Field
- Array
- Grid

The packages described in this section are grouped by the ESMF object they apply to. The creation of custom attributes and custom attribute packages is also possible and is discussed in Section 38.2.7. In some cases it is possible to nest custom packages on top of ESMF packages. Attribute package nesting is described separately in Section 38.3.

Some Attributes come with a controlled vocabulary. A controlled vocabulary is a list of options that can be selected as the value of the attribute. The controlled vocabularies listed in this documentation represent those chosen by the community. They are not exhaustive and users may set these Attributes to a different value if they so choose. The
primary consequence of doing so is that the resulting output may not be recognized by any of the online tools being developed with respect to this controlled vocabulary.

### 38.2.1 Component Attribute packages

There are many attributes that are used to describe components. There are currently 4 predefined component-level Attribute packages, with sub-packages defined for the 2nd:

1. Earth System Modeling Framework (ESMF) Basic
2. Common Information Model (CIM) Main
   - (a) Common Information Model (CIM) Platform
   - (b) International Organization for Standardization (ISO) Responsible Party
   - (c) International Organization for Standardization (ISO) Citation
3. Common Information Model (CIM) Scientific Properties
4. Common Information Model (CIM) Component Properties

#### 1. Earth System Modeling Framework (ESMF) Basic Attribute Package

- Specify with:
  - convention = "ESMF"
  - purpose = "General"
- Output Options:
  - Simple XML
- Description: This package contains several Attributes used to describe model components within the Earth System Modeling Framework (ESMF) ontology.
<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agency</td>
<td>An administrative unit of government.</td>
<td>DoD, DOE, DOI, NASA, NOAA, NSF N/A</td>
</tr>
<tr>
<td>Author</td>
<td>The person who created the content of a book, article, or other source.</td>
<td>C, C++, F77, F90, Java</td>
</tr>
<tr>
<td>CodingLanguage</td>
<td>The computer language in which a unit of software is written.</td>
<td>N/A</td>
</tr>
<tr>
<td>ComponentLongName</td>
<td>The name of a model, model component, simulation, experiment, or dataset with all acronyms spelled out.</td>
<td>N/A</td>
</tr>
<tr>
<td>ComponentShortName</td>
<td>A version of the component name that contains acronyms.</td>
<td>N/A</td>
</tr>
<tr>
<td>Discipline</td>
<td>A subject, theme, category, or general area of interest.</td>
<td>Aerosol, Fisheries, Climate, Carbon Cycle, Hydrology, Land, Ocean, Polar, Sediment, Storm Surge, Turbulence, Weather, Wave, Weather Prediction</td>
</tr>
<tr>
<td>Institution</td>
<td>An organization associated with a model component, simulation, or dataset.</td>
<td>CCA, ESMF, Flume, FMS, OASIS, SWMF</td>
</tr>
<tr>
<td>ModelComponentFramework</td>
<td>The software package or mechanism used to transfer and transform data between model components.</td>
<td>ATMOSPHERE, Earth System, Ice, Lake, Land Ocean, River</td>
</tr>
<tr>
<td>PhysicalDomain</td>
<td>A description of the geographic range being simulated.</td>
<td>N/A</td>
</tr>
<tr>
<td>Version</td>
<td>A specific form or variation of an artifact, i.e. a unit of software or metadata.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

2. Common Information Model (CIM) Main Attribute Package

- Specify with:
  - convention = "CIM 1.5"
  - purpose = "ModelComp"

- CIM Version: CIM 1.5
- CIM URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/)
- Includes:
  - ISO Platform
  - ISO Responsible Party (1 or more – user specifiable)
  - ISO Citation (1 or more – user specifiable)
- Output Options:
Description: The CIM Main Package contains several standalone properties used to describe components. It also serves as the anchor to which other CIM packages are nested. Presently, these additional CIM packages (described further below) can only be created if the CIM Main Package is created. In the future, these packages will be decoupled, so that users may select subsections of the CIM to create and use. This package nests three of the packages below within it; this is described in Section 38.3.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field (&lt;CIM section&gt;:&lt;Entity&gt;:&lt;Field&gt;)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>A multi-line description of the component.</td>
<td>N/A</td>
<td>software:SoftwareComponent:description</td>
</tr>
<tr>
<td>LongName</td>
<td>A version of the component name with all acronyms spelled out.</td>
<td>N/A</td>
<td>software:SoftwareComponent:longName</td>
</tr>
<tr>
<td>MetadataVersion***</td>
<td>The version number of the simulation metadata.</td>
<td>N/A</td>
<td>software:modelComponent:metadataVersion</td>
</tr>
<tr>
<td>ModelType*</td>
<td>A short string describing the discipline of a model component.</td>
<td>Advection, Advection,</td>
<td>software:ModelComponent:type</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Aerosol3D-Sources</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>etc.</td>
<td></td>
</tr>
<tr>
<td>PreviousVersion**</td>
<td>Name of the previous version of a model or model component.</td>
<td>N/A</td>
<td>shared:Reference:name</td>
</tr>
<tr>
<td>PreviousVersionDescription**</td>
<td>A short note about the previous version of the model or model component.</td>
<td>N/A</td>
<td>shared:Relationship:description</td>
</tr>
<tr>
<td>ReleaseDate</td>
<td>The date a model component was issued.</td>
<td>N/A</td>
<td>software:SoftwareComponent:releaseDate</td>
</tr>
<tr>
<td>ShortName*</td>
<td>A version of the component name that contains acronyms.</td>
<td>N/A</td>
<td>software:SoftwareComponent:shortName</td>
</tr>
<tr>
<td>SimulationDuration</td>
<td>The length of time a simulation runs.</td>
<td>N/A</td>
<td>activity:SimulationRun:dateRange</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------</td>
<td>-----</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>SimulationEndDate</td>
<td>The date in simulated time of the end of a model simulation.</td>
<td>N/A</td>
<td>activity:SimulationRun:dateRange</td>
</tr>
<tr>
<td>SimulationEnsembleID</td>
<td>The reference name or number of the ensemble to which a simulation belongs.</td>
<td>N/A</td>
<td>activity:EnsembleMember:ensembleMemberID</td>
</tr>
<tr>
<td>SimulationLongName</td>
<td>The name of the simulation with any acronyms spelled out.</td>
<td>N/A</td>
<td>activity:NumericalActivity:longName</td>
</tr>
<tr>
<td>SimulationNumberOfProcessing Elements</td>
<td>The number of PEs used in the simulation.</td>
<td>N/A</td>
<td>software:Parallelization:processes</td>
</tr>
<tr>
<td>SimulationProjectName</td>
<td>A campaign, such as a model intercomparison project, that may involve multiple groups and experiments.</td>
<td>N/A</td>
<td>activity:Activity:project</td>
</tr>
<tr>
<td>SimulationRationale</td>
<td>The reason for performing a simulation.</td>
<td>N/A</td>
<td>activity:Activity:rationale</td>
</tr>
<tr>
<td>SimulationShortName</td>
<td>The name of the simulation.</td>
<td>N/A</td>
<td>activity:NumericalActivity:shortName</td>
</tr>
<tr>
<td>SimulationStartDate*</td>
<td>The date in simulated time of the start of a model simulation.</td>
<td>N/A</td>
<td>activity:SimulationRun:dateRange</td>
</tr>
<tr>
<td>URL</td>
<td>A URL associated with a model component.</td>
<td>N/A</td>
<td>shared:CI_OnlineResource:linkage</td>
</tr>
</tbody>
</table>
**Version**

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>Version number of the component.</td>
<td>N/A</td>
<td>appended to software:SoftwareComponent:shortName</td>
</tr>
</tbody>
</table>

* Attribute required to be set to produce valid CIM XML output.
* If PreviousVersionDescription is set, PreviousVersion must also be set, to produce valid CIM XML output.
** If not set, defaults to 1.0

### 2.1. CIM Platform Attribute Package

- Specify with:
  - `convention = "CIM 1.5"`
  - `purpose = "Platform"`
- CIM Version: CIM 1.5
- CIM URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/)
- Output Options:
  - CIM XML
- Description: This package describes the platform a particular simulation is run on. It must be created in conjunction with the CIM Main Package (see above). This package is nested within the CIM Main Package (above); see the description in Section 38.3

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>CompilerName**</td>
<td>The brand of the software that takes source code and turns it into an executable.</td>
<td>Absoft, Default, Intel, Lahey, NAG, Pathscale, PGI, PGIGCC, XLF, XLFGCC</td>
<td>shared:Compiler:compilerName</td>
</tr>
<tr>
<td>CompilerVersion**</td>
<td>The specific configuration value of the software used to take source code and turn it into executable code.</td>
<td>N/A</td>
<td>shared:Compiler:compilerVersion</td>
</tr>
<tr>
<td>MachineCoresPerProcessor</td>
<td>The number of sub-divided elements or mini-chips on a computer chip.</td>
<td>N/A</td>
<td>shared:Machine:machineCoresPerProcessor</td>
</tr>
<tr>
<td>MachineDescription</td>
<td>A short note about the machine.</td>
<td>N/A</td>
<td>shared:Machine:machineDescription</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------</td>
<td>-----</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>MachineInterconnectType</td>
<td>The technology used to associate each node in a supercomputer with every other node.</td>
<td>Cray Interconnect, Fat Tree, Gigabit Ethernet, Infiniband, Mixed, Myrinet, Numalink, Quadrics, SP Switch</td>
<td>shared:Machine:machineInterconnect</td>
</tr>
<tr>
<td>MachineMaximumProcessors</td>
<td>The highest number of computer chips on a computer system.</td>
<td>N/A</td>
<td>shared:Machine:machineMaximumProcessors</td>
</tr>
<tr>
<td>MachineName*</td>
<td>The name given to a computer by its system administrators. This is not the brand name of the system.</td>
<td>N/A</td>
<td>shared:Machine:machineName</td>
</tr>
<tr>
<td>MachineOperatingSystem</td>
<td>The software that is responsible for the management and coordination of activities and the sharing of resources of a computer.</td>
<td>Aix, Darwin, Irix64, Linux, SUNOS, Unicos</td>
<td>shared:Machine:machineOperatingSystem</td>
</tr>
<tr>
<td>MachineProcessorType</td>
<td>The type of computer chip used in a particular computer platform.</td>
<td>Altix, AMD x86-64, Bluegene, G4, G5, Intel EM64T, Intel IA-64, Itanium, NEC, Opteron, Origin3800, Pentium 3, Pentium 4, SP, SPARC, X1, Xeon, XT3-4, ZX6000</td>
<td>shared:Machine:machineProcessorType</td>
</tr>
<tr>
<td>MachineSystem</td>
<td>The type of computer system (e.g. vector, parallel, cluster, etc.).</td>
<td>Beowulf, Parallel, Vector</td>
<td>shared:Machine:machineSystem</td>
</tr>
</tbody>
</table>

* Attribute required to be set to produce valid CIM XML output.
* Both CompilerName and CompilerVersion are required to be set, or else neither one, to produce valid CIM XML output; setting one without the other will produce invalid CIM XML output.

### 2.2. ISO Responsible Party Attribute Package

- Specify with:
  - `convention = "ISO 19115"`
  - `purpose = "RespParty"`
- Output Options:
  - CIM XML
- Description: This package is used to describe contacts, authors, institutions, and funding agencies. This package is nested, with one or more user-specifiable instances, within the CIM Main Package(above); see the description in Section 38.3.
- Usage: The Responsible Party package is unique in that the user should first select the type of Responsible Party they wish to define. This is done via the ResponsiblePartyRole attribute within the package. Then the package’s main value is set using the Name attribute.
### Abbreviation
The abbreviation of an individual or organization associated with a model component or simulation.

### EmailAddress
The email address that others can use to ask questions about a model component.

### Name
The name of an author, contact, funder, centre, or principal investigator.

### NameType
The type of entity that Name references.

### PhysicalAddress
The address of the person designated to provide information about a model component.

### ResponsiblePartyRole*
A flag to define the role of the Responsible Party.

### URL
A URL of an individual or organization.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbreviation</td>
<td>The abbreviation of an individual or organization associated with a model component or simulation.</td>
<td>N/A</td>
<td>shared: ResponsibleParty:abbreviation</td>
</tr>
<tr>
<td>EmailAddress</td>
<td>The email address that others can use to ask questions about a model component.</td>
<td>N/A</td>
<td>shared: CI_Address:electronicMailAddress</td>
</tr>
<tr>
<td>Name</td>
<td>The name of an author, contact, funder, centre, or principal investigator.</td>
<td>N/A</td>
<td>shared: CI_ResponsibleParty:individualName, shared: CI_ResponsibleParty:organisationName, shared: CI_ResponsibleParty:positionName (depending on NameType value)</td>
</tr>
<tr>
<td>NameType</td>
<td>The type of entity that Name references. Individual, Organization, Position</td>
<td>Not part of CIM; used to determine which CIM field to use for Name</td>
<td></td>
</tr>
<tr>
<td>PhysicalAddress</td>
<td>The address of the person designated to provide information about a model component.</td>
<td>N/A</td>
<td>shared: CI_Address:deliveryPoint</td>
</tr>
<tr>
<td>ResponsiblePartyRole*</td>
<td>A flag to define the role of the Responsible Party. Author, PI, Contact, Center, Funder</td>
<td>N/A</td>
<td>shared: CI_ResponsibleParty:role</td>
</tr>
<tr>
<td>URL</td>
<td>A URL of an individual or organization.</td>
<td>N/A</td>
<td>shared: CI_OnlineResource:linkage</td>
</tr>
</tbody>
</table>

* Attribute required to be set, when any other attributes in this package are set, to produce valid CIM XML output. It is valid to set none of the attributes in this package. In that case, no corresponding CIM XML output will appear for that Responsible Party package instance, although there may be other populated instances, which, because they have attributes set, will appear in the output.

### 2.3. ISO Citation Attribute Package

- Specify with:
  - `convention = "ISO 19115"`
  - `purpose = "Citation"`

- Output Options:
  - CIM XML

- Description: This package is used to describe references. Examples include a URL or a scientific reference. This package is nested, with one or more user-specifiable instances, within the CIM Main Package (above); see the description in Section [38.3](#).
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date*</td>
<td>The date of the citation.</td>
<td>N/A</td>
<td>shared:CI_Citation:Date</td>
</tr>
<tr>
<td>DOI</td>
<td>The assigned Digital Object Identifier (DOI) of the citation.</td>
<td>N/A</td>
<td>shared:CI_Citation:otherCitationDetails</td>
</tr>
<tr>
<td>LongTitle</td>
<td>The text of the citation or pointer (e.g. URL) that further describes a model component or simulation.</td>
<td>N/A</td>
<td>shared:CI_Citation:collectiveTitle</td>
</tr>
<tr>
<td>PresentationForm</td>
<td>A description of the type of citation.</td>
<td>documentDigital, documentHardcopy, imageDigital, imageHardcopy, mapDigital, mapHardcopy, modelDigital, modelHardcopy, profileDigital, profileHardcopy, tableDigital, tableHardcopy, videoDigital, videoHardcopy</td>
<td>shared:CI_Citation:presentationForm</td>
</tr>
<tr>
<td>ShortTitle*</td>
<td>An abbreviation for the citation. This could be the short scientific citation (e.g. Murphy, 2009) or the title of a web page.</td>
<td>N/A</td>
<td>shared:CI_Citation:title</td>
</tr>
<tr>
<td>URL</td>
<td>Website associated with the citation.</td>
<td>N/A</td>
<td>appended to shared:CI_Citation:collectiveTitle</td>
</tr>
</tbody>
</table>

* Attribute required to be set, when any other attributes in this package are set, to produce valid CIM XML output. It is valid to set none of the attributes in this package. In that case, no corresponding CIM XML output will appear for that Citation package instance, although there may be other populated instances, which, because they have attributes set, will appear in the output.

3. Common Information Model (CIM) Scientific Properties Package

- Specify with:
  - convention = "CIM 1.5"
  - purpose = "SciProp"
- CIM Version: CIM 1.5
- CIM URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/)
- CV Version: 1.3
CV URL: [http://metaforclimate.eu/trac/browser/cmip5q/tags/version-1.3/trunk/cmip5q/cmip5q/data/mindmaps](http://metaforclimate.eu/trac/browser/cmip5q/tags/version-1.3/trunk/cmip5q/cmip5q/data/mindmaps)

Output Options:
- CIM XML

Description: This package is used to describe the scientific properties of a component. The names and values of these properties are part of controlled vocabularies; the recommended version of the controlled vocabulary in the timeframe of this ESMF release is located in a set of mindmap files, located [here](http://metaforclimate.eu/trac/browser/cmip5q/tags/version-1.3/trunk/cmip5q/cmip5q/data/mindmaps). This is the controlled vocabulary that was used for the 5th Coupled Model Intercomparison Project. One or more values can be set (via an array) for a property name.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

---

4. Common Information Model (CIM) Component Properties Package

- Specify with:
  - convention = "CIM 1.5"
  - purpose = "CompProp"

- CIM Version: CIM 1.5

- CIM URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5/)

Output Options:
- CIM XML

Description: This package is used to specify any number of custom, user-defined attributes of a component and have them output in valid CIM XML format. This differs from the scientific properties package above in that the names and values are custom, not part of any controlled vocabulary. It also differs from a custom attribute package (see Section 38.2.7) in that this package has a standard convention and purpose, which is used to control the output of the user-defined attributes in standard CIM XML format. One or more values can be set (via an array) for an attribute name.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;User-defined name&gt;</td>
<td>&lt;User-defined definition&gt;</td>
<td>N/A</td>
<td>software:SoftwareComponent: component-Properties</td>
</tr>
</tbody>
</table>
38.2.2 State Attribute packages

There is currently only 1 predefined State-level Attribute package:

1. ESMF Basic

1. ESMF Basic State Attribute Package

- Specify with:
  - convention = "ESMF"
  - purpose = "General"

- Output Options:
  - Tab-delimited
  - Simple XML

- Description: This package is used to define whether an ESMF State object is an Import State or Export State.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intent</td>
<td>An indication of whether a state is imported into or exported from a particular model component. This refers to coupling, and not history output.</td>
<td>Export, Import</td>
</tr>
</tbody>
</table>

38.2.3 Field Attribute packages

Several standards exist to describe fields. There are currently 4 predefined Field-level Attribute packages:

1. Common Information Model (CIM) Inputs
2. Earth System Grid General
3. Climate Forecast (CF) Convention Extended
4. Climate Forecast (CF) Convention General

1. Common Information Model (CIM) Inputs

- Specify with:
  - convention = "CIM 1.5"
  - purpose = "Inputs"
- CIM Version: CIM 1.5
- CIM URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5)
- Includes:
  - ESMF General
  - CF Extended
  - CF General
- Output Options:
  - CIM XML
- Description: This package is used to describe a simulation and the input (initial and boundary) conditions used in that simulation. It is also used to describe any ancillary data sets that contain input condition variables. This package should not be used to describe the variables in an unconfigured model component. A pre-defined Attribute package for that case will be implemented in a future release of ESMF. This package nests the ESMF General, CF Extended, and CF General Field packages (below) within it; this is described in Section 38.3. The attribute values within these ESMF and CF nested packages currently appear in the Component Properties section of the CIM output file. A separate Component Properties package may be developed for this purpose in a future ESMF release.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
<th>CIM Schema Field (&lt;CIM section&gt;:&lt;Entity&gt;:&lt;Field&gt;)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CouplingPurpose*</td>
<td>The form of the input condition (e.g. initial condition or boundary condition).</td>
<td>Ancillary, Boundary, Initial</td>
<td>software:Coupling:purpose</td>
</tr>
<tr>
<td>CouplingSource*</td>
<td>The component the input condition is coming from.</td>
<td>N/A</td>
<td>software:Coupling:couplingSource</td>
</tr>
<tr>
<td>CouplingTarget*</td>
<td>The component the input condition is going to.</td>
<td>N/A</td>
<td>software:Coupling:couplingTarget</td>
</tr>
<tr>
<td>Description</td>
<td>A multi-line description of the input.</td>
<td>N/A</td>
<td>software:Coupling:description</td>
</tr>
<tr>
<td>Frequency</td>
<td>The frequency (e.g. 2 months or 5 days) that a field from one component is input to another.</td>
<td>n Seconds, n Minutes, n Hours, n Days, n Months, n Years, n Decades, n Centuries</td>
<td>software:Timing:rate</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
<td>Sample Values</td>
<td>Notes</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>SpatialRegriddingMethod</td>
<td>Method used to interpolate a field from one grid (source grid) to another (target grid).</td>
<td>Linear, Nearest-Neighbor, Cubic, Conservative-First-Order, Conservative-Second-Order, Conservative, Non-Conservative</td>
<td>software:SpatialRegridding: spatialRegriddingStandardMethod</td>
</tr>
<tr>
<td>SpatialRegriddingDimension</td>
<td>Dimension of the regridding method.</td>
<td>1D, 2D, 3D</td>
<td>software:SpatialRegridding: spatialRegriddingDimension</td>
</tr>
<tr>
<td>Technique</td>
<td>The software package or mechanism used to transfer and transform data between model components.</td>
<td>CCSM Flux Coupler, ESMF, Files, FMS, MCT, OASIS3, Shared</td>
<td>N/A</td>
</tr>
<tr>
<td>TimeTransformationType</td>
<td>Temporal transformation performed on the input field before or after regridding onto the target grid.</td>
<td>Exact, None, Time Accumulation, Time Average, Time Interpolation</td>
<td>software:TimeTransformation:mappingType</td>
</tr>
</tbody>
</table>

* Attribute required to be set, when any other attributes in this package are set, to produce valid CIM XML output. It is valid to set none of the attributes in this package. In that case, no corresponding CIM XML output will appear for that Inputs package.

2. Earth System Modeling Framework (ESMF) Field

- Specify with:
  - convention = "ESMF"
  - purpose = "General"

- Includes:
  - CF Extended
  - CF General

- Output Options:
Description: This package nests the CF Extended and CF General packages (below) within it; this is described in Section 38.3.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intent</td>
<td>An indication of whether a variable is exported or imported. This refers to coupling and not history output.</td>
<td>Export, Import</td>
</tr>
</tbody>
</table>

### 3. Climate Forecast (CF) Convention Extended

- Specify with:
  - `convention = "CF"`
  - `purpose = "Extended"`
- Includes:
  - CF General
- Output Options:
  - Tab-delimited
  - Simple XML
  - CIM XML (when part of the CIM Inputs package)
- Description: The CF standard for fields contains an optional standard_name Attribute. Standard names are controlled vocabularies and not every variable in the earth system sciences contains a standard name. Because of this, ESMF implemented this optional Attribute in its own package. This package nests the CF General package (below) within it; this is described in Section 38.3.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>StandardName</td>
<td>The approved CF standard name for a variable if it exists.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

### 4. Climate Forecast (CF) Convention General

- Specify with:
  - `convention = "CF"`
  - `purpose = "General"`
- Output Options:
  - Tab-delimited
  - Simple XML
• Description: The climate and forecast (CF) convention contains metadata that is designed to promote the processing and sharing of files created with the NetCDF API. The CF conventions are increasingly gaining acceptance and have been adopted by a number of projects and groups as a primary standard. The conventions define metadata that provide a definitive description of what the data in each variable represents, and the spatial and temporal properties of the data. This enables users of data from different sources to decide which quantities are comparable, and facilitates building applications with powerful extraction, regridding, and display capabilities.

The ESMF CF Attribute package contains the three mandatory Attributes required to describe fields.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>LongName</td>
<td>An ad-hoc long descriptive name which may, for example, be used for labeling plots</td>
<td>N/A</td>
</tr>
<tr>
<td>ShortName*</td>
<td>The short_name is technically not part of the CF standard but is commonly the name of the variable on the output file and so is distinct from the long_name</td>
<td>N/A</td>
</tr>
<tr>
<td>Units</td>
<td>The value of the units attribute is a string that can be recognized by UNIDATA’s Udunits package</td>
<td>N/A</td>
</tr>
</tbody>
</table>

* Attribute required to be set, if any attributes are set within this package, the CF/Extended, or ESMF/General package, to produce valid CIM XML output. It is valid to set none of the attributes in this package, the CF/Extended, or ESMF/General package, in which case no field CIM output will be produced.

### 38.2.4 Array Attribute packages

At this time the Array packages are the same as the Field packages.

### 38.2.5 Grid Attribute packages

There are 2 grid attribute packages in ESMF.

1. CIM 1.5.1 grids
2. ESMF Grid

1. grids

- Specify with:
  - convention = "CIM 1.5.1"
  - purpose = "grids"
• CIM Version: CIM 1.5.1
• CIM Schema URL: [http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5.1/](http://metaforclimate.eu/trac/browser/CIM/tags/version-1.5.1/)
• Output Options:
  – Simple XML
  – This package can be used to create a CIM 1.5.1 compliant grids XML file.
• Description: This package contains the information necessary to create a CIM 1.5.1 compliant grids XML file. The Attributes in this package are populated entirely by internal ESMF Grid information, no user intervention beyond the addition of the package is needed to create this package.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>A unique name used to identify this Grid, this is taken from the internal name of the Grid object</td>
<td>N/A</td>
</tr>
<tr>
<td>isLeaf</td>
<td>A boolean value used to describe whether there are any nested mosaics inside of this mosaic</td>
<td>true, false</td>
</tr>
<tr>
<td>gridType</td>
<td>A text description of the the type of the grid</td>
<td>cubed_sphere, displaced_pole, icosahedral_geodesic, reduced_gaussian, regular_lat_lon, spectral_gaussian, tripolar, yin_yang, composite, other</td>
</tr>
<tr>
<td>numTiles</td>
<td>The number of tiles in this Grid</td>
<td>N/A</td>
</tr>
<tr>
<td>shortName</td>
<td>A short name to identify this Grid</td>
<td>N/A</td>
</tr>
<tr>
<td>longName</td>
<td>A long name describing this Grid in detail</td>
<td>N/A</td>
</tr>
<tr>
<td>gridTile</td>
<td>The specific number for this tile of the Grid</td>
<td>N/A</td>
</tr>
<tr>
<td>discretizationType</td>
<td>The type of discretization that is used in this Grid</td>
<td>logically_rectangular, structured_rectangular, unstructured_rectangular, pixel_based_catchment, unstructured_polygonal, spherical_harmonics, other</td>
</tr>
<tr>
<td>geometryType</td>
<td>The type of geometry that best describes this Grid</td>
<td>ellipsoid, plane, sphere</td>
</tr>
<tr>
<td>numDims</td>
<td>The number of dimensions in this Grid</td>
<td>N/A</td>
</tr>
<tr>
<td>xcoords</td>
<td>The x (or longitude) coordinates of this Grid</td>
<td>N/A</td>
</tr>
<tr>
<td>ycoords</td>
<td>The y (or latitude) coordinates of the Grid</td>
<td>N/A</td>
</tr>
</tbody>
</table>
2. ESMF Grid

- Specify with:
  - `convention = "ESMF"
  - `purpose = "General"

- Description: This package is used by ESMF to track internal ESMF Grid information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Controlled Vocabulary</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegDecompX</td>
<td>The number of DEs in X a particular grid is decomposed into.</td>
<td>N/A</td>
</tr>
<tr>
<td>RegDecompY</td>
<td>The number of DEs in Y a particular grid is decomposed into.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

38.2.6 Table of available Attributes

The following is an alphabetical list of all the attributes implemented in ESMF, their definitions, and which packages they are contained within.

<table>
<thead>
<tr>
<th>Name</th>
<th>Definition</th>
<th>Attribute Package</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agency</td>
<td>An administrative unit of government.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td>CodingLanguage</td>
<td>The computer language in which a unit of software is written.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td>CompilerName</td>
<td>The brand of the software that takes source code and turns it into an executable.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>CompilerVersion</td>
<td>The specific configuration value of the software used to take source code and turn it into executable code.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>CouplingPurpose</td>
<td>The form of the input condition (e.g. initial condition or boundary condition).</td>
<td>CIM Inputs</td>
</tr>
<tr>
<td>CouplingSource</td>
<td>The component the input condition is coming from.</td>
<td>CIM Inputs</td>
</tr>
<tr>
<td>CouplingTarget</td>
<td>The component the input condition is going to.</td>
<td>CIM Main, CIM Inputs</td>
</tr>
<tr>
<td>Description</td>
<td>A multi-line description of a component or input.</td>
<td></td>
</tr>
<tr>
<td>Date</td>
<td>The date of the citation.</td>
<td>ISO Citation</td>
</tr>
<tr>
<td>DOI</td>
<td>The assigned Digital Object Identifier (DOI) of the citation.</td>
<td>ISO Citation</td>
</tr>
<tr>
<td>EmailAddress</td>
<td>The email address that others can use to ask questions about a model component.</td>
<td>ISO Responsible Party</td>
</tr>
<tr>
<td>Frequency</td>
<td>The frequency (e.g. months, days) that a field from one component is input to another.</td>
<td>CIM Inputs</td>
</tr>
<tr>
<td>FullName</td>
<td>The name of a model, model component, simulation, experiment, or dataset with all acronyms spelled out.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td>Institution</td>
<td>An organization associated with a model component, simulation, or dataset.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td>Intent</td>
<td>An indication of whether a field or state is imported into or exported from a particular model component. This refers to coupling, and not history output.</td>
<td>ESMF State, ESMF Field</td>
</tr>
<tr>
<td>LongName</td>
<td>The name of an object with all acronyms spelled out. For fields, it is an ad-hoc long descriptive name which may, for example, be used for labeling plots.</td>
<td>CIM Main, CF General</td>
</tr>
<tr>
<td>LongTitle</td>
<td>The text of the citation or pointer (e.g. URL) that further describes a model component or simulation.</td>
<td>ISO Citation</td>
</tr>
<tr>
<td>MachineCoresPerProcessor</td>
<td>The number of sub-divided elements or mini-chips on a computer chip.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineDescription</td>
<td>A short note about the machine.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineInterconnectType</td>
<td>The technology used to associate each node in a supercomputer with every other node.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineMaximumProcessors</td>
<td>The highest number of computer chips on a computer system.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineName</td>
<td>The name given to a computer by its system administrators. This is not the brand name of the system.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineOperatingSystem</td>
<td>The software that is responsible for the management and coordination of activities and the sharing of resources of a computer.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineProcessorType</td>
<td>The type of computer chip used in a particular computer platform.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td>MachineSystem</td>
<td>The type of computer system (e.g. vector, parallel, cluster, etc.).</td>
<td>CIM Platform</td>
</tr>
<tr>
<td><strong>MachineVendor</strong></td>
<td>The brand name of a computer system.</td>
<td>CIM Platform</td>
</tr>
<tr>
<td><strong>MetadataVersion</strong></td>
<td>The version number of the simulation metadata.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>ModelComponentFramework</strong></td>
<td>The software package or mechanism used to transfer and transform data between model components.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td><strong>ModelType</strong></td>
<td>A short string describing the discipline of a model component.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>The name of an author, contact, funder, centre, or principal investigator.</td>
<td>ISO Responsible Party</td>
</tr>
<tr>
<td><strong>NameType</strong></td>
<td>The type of entity that Name references.</td>
<td>ISO Responsible Party</td>
</tr>
<tr>
<td><strong>PhysicalAddress</strong></td>
<td>The address of the person designated to provide information about a model component.</td>
<td>ISO Responsible Party</td>
</tr>
<tr>
<td><strong>PhysicalDomain</strong></td>
<td>A description of the geographic range being simulated.</td>
<td>ESMF Basic Component</td>
</tr>
<tr>
<td><strong>PresentationForm</strong></td>
<td>A description of the type of citation.</td>
<td>ISO Citation</td>
</tr>
<tr>
<td><strong>PreviousVersion</strong></td>
<td>Name of the previous version of a model or model component.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>PreviousVersionDescription</strong></td>
<td>A short note about the previous version of the model or model component.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>ReleaseDate</strong></td>
<td>The year a model component was issued.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>RegDecompX</strong></td>
<td>The number of DEs in X a particular grid is decomposed into.</td>
<td>ESMF Grid</td>
</tr>
<tr>
<td><strong>RegDecompY</strong></td>
<td>The number of DEs in Y a particular grid is decomposed into.</td>
<td>ESMF Grid</td>
</tr>
<tr>
<td><strong>ResponsiblePartyRole</strong></td>
<td>A flag to define the role of the Responsible Party.</td>
<td>ISO Responsible Party</td>
</tr>
<tr>
<td><strong>ShortName</strong></td>
<td>For component: a version of the component name that contains acronyms. For field: The short_name is technically not part of the CF standard but is commonly the name of the variable on the output file and so is distinct from the long_name.</td>
<td>CIM Main, CF General</td>
</tr>
<tr>
<td><strong>ShortTitle</strong></td>
<td>An abbreviation for the citation. This could be the short scientific citation (e.g. Murphy, 2009) or the title of a web page.</td>
<td>ISO Citation</td>
</tr>
<tr>
<td><strong>SimulationDuration</strong></td>
<td>The length of time a simulation runs.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationEndDate</strong></td>
<td>The date in simulated time of the end of a model simulation.</td>
<td>CIM Main</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td><strong>SimulationEnsembleID</strong></td>
<td>The reference name or number of the ensemble to which a simulation belongs.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationLongName</strong></td>
<td>The name of the simulation with any acronyms spelled out.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationNumberOfProcessingElements</strong></td>
<td>The number of PEs used in the simulation.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationProjectName</strong></td>
<td>A campaign, such as a model intercomparison project, that may involve multiple groups and experiments.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationRationale</strong></td>
<td>The reason for performing a simulation.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationStartDate</strong></td>
<td>The date in simulated time of the start of a model simulation.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SimulationShortName</strong></td>
<td>The name of the simulation.</td>
<td>CIM Main</td>
</tr>
<tr>
<td><strong>SpatialRegriddingMethod</strong></td>
<td>Method used to interpolate a field from one grid (source grid) to another (target grid).</td>
<td>CIM Inputs</td>
</tr>
<tr>
<td><strong>SpatialRegriddingDimension</strong></td>
<td>Dimension of the regridding method.</td>
<td>CIM Inputs</td>
</tr>
<tr>

<td>URL of the object being described. Exists in multiple packages.</td>
<td>CIM Main, ISO Responsible Party, ISO Citation</td>
</tr>
<tr>
<td><strong>Units</strong></td>
<td>The value of the units attribute is a string that can be recognized by UNIDATA’s Udunits package.</td>
<td>CF General</td>
</tr>
<tr>
<td><strong>Version</strong></td>
<td>A specific form or variation of an artifact i.e. a unit of software or metadata.</td>
<td>CIM Main, ESMF Basic Component</td>
</tr>
</tbody>
</table>
38.2.7 Custom Attribute packages

ESMF allows for the creation of custom attribute packages, each of which has a user-defined convention and purpose, as well as a set of user-defined attributes. This can be done to augment one of the pre-defined packages (via package nesting 38.3) or to create a suite of attributes unique to the user. A custom attribute package currently outputs only in simple XML format, when used as a stand-alone package (not when used to augment a pre-defined package). Examples of how to create such custom packages are contained in Sections 38.7.2 and 38.7.3.

38.3 Attribute Packages Nesting

Nesting is a way of creating larger Attribute packages out of smaller ones and allows users to add the attributes they want to an existing package. It is very useful when combining a custom package with a pre-defined package. One or more child Attribute packages can be nested within a parent package, and this can be repeated multiple times, allowing a full Attribute tree (hierarchical) structure to be created. Breaking Attributes up into smaller packages that are then nested also allows for the construction of complex attribute trees where certain structures repeat themselves, allowing for Attribute package reusability.

Several of the ESMF pre-defined packages, when added to an ESMF object, are created with nested packages:

CIM Main – Component package – is a nest with three child packages:

1. CIM Platform
2. CIM Responsible Party (one or more – user specifiable)
3. CIM Citation (one or more – user specifiable)

CIM Inputs – Field package – is a nest with one child package:

1. ESMF General (with CF Extended and CF General packages nested within it)

ESMF General – Field package – is a nest with one child package:

1. CF Extended (with a CF General package nested within it)

CF Extended – Field package – is a nest with one child package:

1. CF General

An explanation of the Attribute packages specifiers is in order at this point. The purpose specifier is really just meant as an additional means, beyond the use of "convention", to specify Attribute packages. One could imagine that the CF convention would want to be able to have Attribute packages divided up in some fashion, which ESMF could then keep track of with the purpose specifier. It was added with the intention of allowing Attributes, and packages, maximum flexibility. Take the Field’s ESMF standard Attribute package for example. This package is made up of three nested Attribute packages. The lowest one is made up of three Attributes with convention=CF and purpose=General. The next level contains one Attribute with convention=CF but purpose=Extended. On top of this is the convention=ESMF package, also with purpose=General.
38.4 Export Formats

The ESMF_AttributeWrite() interface is used to write the contents of an Attribute package to a file. This routine can be called on any ESMF object that is capable of holding Attribute packages. It can also write out all Attributes in Attribute packages with the same convention and purpose throughout an entire ESMF object hierarchy.

There are three primary ways of exporting Attributes:

1. Tab-delimited ASCII
2. Simple XML
3. CIM XML

The flag that is used in the ESMF_AttributeWrite() interface to determine which format for writing the Attribute packages is called the ESMF_AttWriteFlag, with values as described below. The resulting file will be placed in the execution directory after it is written and closed.

38.4.1 Tab-delimited ASCII

When ESMF_AttWriteFlag is set to ESMF_ATTWRITE_TAB (the default), a tab-delimited ascii file containing name-value pairs of attributes in the packages will be written. The file will be named for the name of the ESMF object from which ESMF_AttributeWrite() is called. The suffix will be .stdout.

38.4.2 Simple XML

When ESMF_AttWriteFlag is set to ESMF_ATTWRITE_XML, an XML file containing name-value pairs of attributes in the packages will be written. The file will be named for the name of the ESMF object from which ESMF_AttributeWrite() is called. The suffix will be .xml.

38.4.3 CIM XML

When the ESMF object from which ESMF_AttributeWrite() is called is a Component, and the Attribute package convention="CIM1.5", and the purpose="ModelComp", and ESMF_AttWriteFlag is set to ESMF_ATTWRITE_XML, an XML file conforming to the CIM standard will be written. The file will contain Attributes from the entire Component tree and their contained Fields. The file will be named for the name of the ESMF Component object from which ESMF_AttributeWrite() is called, and the suffix will be .xml.

There is a deviation from the standard CIM in the ESMF code: if the top-level object is not a component, or the proper convention ("CIM 1.5") or purpose ("ModelComp") are not used, then the simple XML logic will be followed, and elements such as, "variable_set" and "variable" may be found in the exported XML.

38.4.4 CIM 1.5.1 grids XML

** This is a prototype capability.

When the ESMF object from which ESMF_AttributeWrite() is called is a Grid (or it contains a Grid), and the Attribute package convention="CIM 1.5.1", and the purpose="grids", and ESMF_AttWriteFlag is set to ESMF_ATTWRITE_XML, an XML file conforming to the CIM 1.5.1 grids standard will be written. The file will
be named for the name of the ESMF Component object from which `ESMF_AttributeWrite()` is called, and the suffix will be `.xml`. This file is written by pulling internal information out of the Grid object. It is currently functional for one- and two-dimensional Grids.

### 38.5 Accessing object information through Attribute

Internal ESMF class information can be retrieved through the Attribute class with the `ESMF_AttributeGet()` interface. The Grid class is the prototype for this capability. Internal information is retrieved by specifying the name in `ESMF_AttributeGet()` as the keyword of the desired argument from one of the `ESMF_GridGet()` interfaces. The ‘value’ of the Attribute must be of the corresponding type that is required to retrieve the desired piece of information. There are a few pieces of information that cannot be retrieved from the Grid through the Attribute interface at this time, see Tables 13-15 to determine what is currently available.

The name of an Attribute that represents internal class information must have ‘ESMF:’ prepended. This is to indicate that the information should be retrieved directly from class methods. The input arguments must not have the ‘ESMF:’ string prepended, and they should be specified as a character string with the name and value separated by an equal sign. For example, the `localDe=0` would be specified like this: ‘localDe=0’.

Note: Attribute access to internal class information does not have the normal Attribute restriction that the values of the Attributes must be consistent across the current VM.

There is an example of how to use this capability in Section 38.7.5.

The name, type, input arguments and original Grid interface for each of the pieces of internal Grid information that can be retrieved through the Attribute class are listed in Tables 13-15. The name of the Attribute is specified by the character strings in the first column, and the type of the output is specified in the second column. The third column specifies which input information is required (or optional) to retrieve the information and the fourth column gives a link to a detailed description of the input arguments.

Note: The following pieces of Grid information cannot be retrieved with this method: `distgrid`, `coordDimMap`, `arbIndexList`, and `coord`.

### 38.6 Constants

#### 38.6.1 ESMF.AttGetCount

**DESCRIPTION:**
Indicates which type of Attribute object count to return.

The type of this flag is:

type(ESMF_AttGetCountFlag)

The valid values are:

- **ESMF_AttGetCount_Attribute** This option will allow the routine to return the number of single Attributes.
- **ESMF_AttGetCount_AttributePackage** This option will allow the routine to return the number of Attribute packages.
- **ESMF_AttGetCount_AttributeLink** This option will allow the routine to return the number of Attribute links.
Table 13: This table shows general Grid information that can be retrieved with character string inputs to the ESMF_AttributeGet() interface

38.6.2 ESMF_ATTGETCOUNT_TOTAL

This option will allow the routine to return the total number of Attributes.

38.6.2 ESMF_ATTTREE

DESCRIPTION:
Indicates whether or not to descend the Attribute hierarchy for the present operation.

The type of this flag is:
\texttt{type(ESMF\_AttTreeFlag)}

The valid values are:

\texttt{ESMF\_ATTTREE\_OFF} This option will allow the routine to only descend the first base level of the Attribute hierarchy.

\texttt{ESMF\_ATTTREE\_ON} This option will allow the routine to descend the entire Attribute hierarchy.

38.6.3 ESMF_ATTWRITE

DESCRIPTION:
Indicates which file format to use in the write operation.

The type of this flag is:
\texttt{type(ESMF\_AttWriteFlag)}

The valid values are:

\texttt{ESMF\_ATTWRITE\_XML} This option will allow the routine to write in xml format.

\texttt{ESMF\_ATTWRITE\_TAB} This option will allow the routine to write in tab-delimited format.

38.7 Use and Examples

This section describes the use of the Attribute class. There are eight examples that follow, which outline the use of Attributes at three increasing levels of difficulty. The first example covers basic Attribute manipulations on the gridded

</table>
Component. The second example covers the Attribute package capabilities, including Attribute package nesting and Attribute hierarchy linking. The third example covers Attribute management in a distributed environment and the I/O utilities. These examples will be best understood if followed in an ascending order from basic to advanced. The fourth example shows how to use the CIM Attribute packages. The last four examples cover setting of Attribute packages and custom Attributes from an XML file.

38.7.1 Basic Attribute usage

This example illustrates the most basic usage of the Attribute class. This demonstration of Attribute manipulation is limited to the gridded Component, but the same principles apply to the coupler Component, State, Grid, FieldBundle, Field, ArrayBundle and Array. The functionality that is demonstrated includes setting and getting Attributes, working with Attributes of different types and lists, removing Attributes, and getting default Attributes. Various other uses of ESMF_AttributeGet() is covered in detail in the last section. The first thing we must do is declare variables and initialize ESMF:

```fortran
! Use ESMF framework module
use ESMF
use ESMF_TestMod
implicit none

! Local variables
integer          :: rc, finalrc, petCount, localPet, &
                 itemCount, count, result

! Local variables
integer(ESMF_KIND_I4) :: inI4
integer(ESMF_KIND_I4), dimension(3) :: inI4l
integer(ESMF_KIND_I8) :: inI8
integer(ESMF_KIND_I8), dimension(3) :: inI8l
real(ESMF_KIND_R4)    :: inR4
real(ESMF_KIND_R4), dimension(3) :: inR4l
real(ESMF_KIND_R8)    :: inR8
real(ESMF_KIND_R8), dimension(3) :: inR8l
character(ESMF_MAXSTR) :: inChar
character(ESMF_MAXSTR), dimension(3) :: inCharl, &
                                     defaultCharl, dfltoutCharl
character(ESMF_MAXSTR), dimension(8) :: outCharl
logical                     :: inLog
logical, dimension(3)      :: inLogl, value
character(ESMF_MAXSTR)     :: testname
character(ESMF_MAXSTR)     :: failMsg

! initialize ESMF
finalrc = ESMF_SUCCESS
call ESMF_Initialize(vm=vm, defaultlogfilename="AttributeEx.Log", &
                     logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
```

811
! get the vm
  call ESMF_VMGet(vm, petCount=petCount, localPet=localPet, rc=rc)

We will construct the gridded Component which will be responsible for all of the Attributes we will be manipulating.

if (petCount<4) then
  gridcomp = ESMF_GridCompCreate(name="gridcomp", &
  petList=(/0/), rc=rc)
else
  gridcomp = ESMF_GridCompCreate(name="gridcomp", &
  petList=(/0,1,2,3/), rc=rc)
endif

We can set Attributes using the ESMF_AttributeSet() command. Attributes can be any of several different types, all of which are demonstrated here.

inI4 = 4
inI4l = (/1,2,3/)
inI8 = 4
inI8l = (/1,2,3/)
inR4 = 4
inR4l = (/1,2,3/)
inR8 = 4
inR8l = (/1,2,3/)
inChar = "Character string 4"
inCharl = (/"Character string 1", &
  "Character string 2", &
  "Character string 3" /)
inLog = .true.
inLogl = (/.true., .false., .true. /)

  call ESMF_AttributeSet(gridcomp, name="ESMF_I4name", value=inI4, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_I4namelist", &
    valueList=inI4l, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_I8name", value=inI8, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_I8namelist", &
    valueList=inI8l, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_R4name", value=inR4, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_R4namelist", &
    valueList=inR4l, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_R8name", value=inR8, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_R8namelist", &
    valueList=inR8l, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_Charname", value=inChar, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_Charnamelist", &
    valueList=inCharl, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_Logname", value=inLog, rc=rc)

  call ESMF_AttributeSet(gridcomp, name="ESMF_Lognamelist", &
    valueList=inLogl, rc=rc)
We can retrieve Attributes by issuing the ESMF_AttributeGet() command. This command can also be used with an optional default value (or value list) so that if the Attribute is not found a value is returned without an error code. Removal of Attributes is also possible, and is demonstrated here as well. One of the Attributes previously created will be retrieved, then removed, then retrieved again using a default return value. In order to use the default return value capabilities, we must first set up a default parameter.

defaultCharl = (/ "Character string 4", &
                  "Character string 5", &
                  "Character string 6" /)

itemCount=3
call ESMF_AttributeGet(gridcomp, name="Character_namelist", &
                        valueList=outCharl(1:5), itemCount=itemCount, rc=rc)

call ESMF_AttributeRemove(gridcomp, name="Character_namelist", rc=rc)
call ESMF_AttributeGet(gridcomp, name="Character_namelist", &
valueList=dfltoutCharl, defaultvalueList=defaultCharl,rc=rc)

There are more overloaded instances of ESMF_AttributeGet() which allow the retrieval of Attribute information by name or index number, or a query for the count of the Attributes on a certain object. These capabilities are demonstrated here by first retrieving the name of an Attribute using the index number, keep in mind that these index numbers start from 1. Then the name that is retrieved is used to get other information about the Attribute, such as the typekind, and the number of items in the value of the Attribute. This information is then used to actually retrieve the Attribute value. Then the count of the number of Attributes on the object will be retrieved.

call ESMF_AttributeGet(gridcomp, attributeIndex=11 , name=name, rc=rc)

call ESMF_AttributeGet(gridcomp, name=name, typekind=tk, &
ItemCount=itemCount, rc=rc)

if (tk==ESMF_TYPEKIND_Logical .AND. itemCount==3) then
    call ESMF_AttributeGet(gridcomp, name=name, valueList=value, rc=rc)
endif

call ESMF_AttributeGet(gridcomp, count=count, rc=rc)

38.7.2 Attribute packages

This example is slightly more complex than the example presented in section 38.7.1 and illustrates the use of the Attribute class to create Attribute hierarchies using Attribute packages. A gridded Component is used in conjunction with two States, a FieldBundle, and various realistic Fields to create an Attribute hierarchy and copy it from one State to another. Attribute packages are created on the Component and Fields, and the standard Attributes in each package are used in the Attribute hierarchy. The Attribute package nesting capability is demonstrated by nesting the standard ESMF supplied packages for the Fields inside a user specified Attribute package with a customized convention.

We must construct the ESMF objects that will be responsible for the Attributes we will be manipulating. These objects include the gridded Component, two States, a FieldBundle, and 10 Fields. In this trivial example we are constructing empty Fields with no underlying Grid.

if (petCount<4) then
    gridcomp = ESMF_GridCompCreate(name="gridded_comp_ex2", &
    petList=(/0/), rc=rc)
else
    gridcomp = ESMF_GridCompCreate(name="gridded_comp_ex2", &
        petList=([0,1,2,3]), rc=rc)
endif

importState = ESMF_StateCreate(name="importState", &
    stateintent=ESMF_STATEINTENT_IMPORT, rc=rc)

exportState = ESMF_StateCreate(name="exportState", &
    stateintent=ESMF_STATEINTENT_EXPORT, rc=rc)

DPEDT = ESMF_FieldEmptyCreate(name='DPEDT', rc=rc)

DTDT = ESMF_FieldEmptyCreate(name='DTDT', rc=rc)

DUDT = ESMF_FieldEmptyCreate(name='DUDT', rc=rc)

DVDT = ESMF_FieldEmptyCreate(name='DVDT', rc=rc)

PHIS = ESMF_FieldEmptyCreate(name='PHIS', rc=rc)

QTR = ESMF_FieldEmptyCreate(name='QTR', rc=rc)

CNV = ESMF_FieldEmptyCreate(name='CNV', rc=rc)

CONVCPT = ESMF_FieldEmptyCreate(name='CONVCPT', rc=rc)

CONVKE = ESMF_FieldEmptyCreate(name='CONVKE', rc=rc)

CONVPHI = ESMF_FieldEmptyCreate(name='CONVPHI', rc=rc)

fbundle = ESMF_FieldBundleCreate(name="fbundle", rc=rc)
Now we can add Attribute packages to all of the appropriate objects. We will use the ESMF supplied Attribute packages for the Fields and the Component. On the Fields, we will first use \texttt{ESMF\_AttributeAdd()} to create standard Attribute packages, then we will nest customized Attribute packages around the ESMF standard Attribute packages. In this simple example the purpose for the Attribute packages will be specified as "General" in all cases.

\begin{verbatim}
convESMF = 'ESMF'
convCC = 'CustomConvention'
purpGen = 'General'

attrList(1) = 'Coordinates'
attrList(2) = 'Mask'

! DPEDT
call ESMF\_AttributeAdd(DPEDT, convention=convESMF, purpose=purpGen, &
                       rc=rc)

call ESMF\_AttributeAdd(DPEDT, convention=convCC, purpose=purpGen, &
                       attrList=attrList, nestConvention=convESMF, nestPurpose=purpGen, &
                       rc=rc)

... and so on for the other 9 Fields.
\end{verbatim}

The standard Attribute package currently supplied by ESMF for Field contains 6 Attributes, 2 of which are set automatically. The remaining 4 Attributes in the standard Field Attribute package must be set manually by the user. We must also set the Attributes of our own custom Attribute package, which is built around the ESMF standard Attribute package.

\begin{verbatim}
name1 = 'ShortName'
name2 = 'StandardName'
name3 = 'LongName'
name4 = 'Units'

! DPEDT
value1 = 'DPEDT'
value2 = 'tendency_of_air_pressure'
value3 = 'Edge pressure tendency'
value4 = 'Pa s\(^{-1}\)'
! Custom Attributes

! retrieve Attribute package
call ESMF\_AttributeGetAttPack(DPEDT, convCC, purpGen, &
                       attpack=attpack, rc=rc)

call ESMF\_AttributeSet(DPEDT, name='Coordinates', value='latlon', &
                       convention=convCC, purpose=purpGen, rc=rc)

call ESMF\_AttributeSet(DPEDT, name='Mask', value='yes', &
                       convention=convCC, purpose=purpGen, rc=rc)
\end{verbatim}
! ESMF Attributes

! retrieve Attribute package
call ESMF_AttributeGetAttrPack(DPEDT, convESMF, purpGen, &
attpack=attpack, rc=rc)

call ESMF_AttributeSet(DPEDT, name2, value2, convention=convESMF, &
purpose=purpGen, rc=rc)

call ESMF_AttributeSet(DPEDT, name3, value3, convention=convESMF, &
purpose=purpGen, rc=rc)

call ESMF_AttributeSet(DPEDT, name4, value4, convention=convESMF, &
purpose=purpGen, rc=rc)

... and so on for the other 9 Fields.
The standard Attribute package currently supplied by ESMF for Component contains 10 Attributes. These Attributes
conform to both the ESG and CF conventions, and must be set manually.

! retrieve Attribute package
call ESMF_AttributeGetAttrPack(gridcomp, convESMF, purpGen, attpack=attpack, rc=rc)

call ESMF_AttributeSet(gridcomp, 'Agency', 'NASA', &
convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp, 'Author', 'Max Suarez', &
convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp, 'CodingLanguage', &
'Fortran 90', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp, 'Discipline', &
'Atmosphere', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp, 'ComponentLongName', &
'Goddard Earth Observing System Version 5 Finite Volume Dynamical Core', &
convention=convESMF, purpose=purpGen, rc=rc)
Adding the Fields to the FieldBundle will automatically “link” the Attribute hierarchies. The same type of link will be generated when adding a FieldBundle to a State.

call ESMF_FieldBundleAdd(fbundle, (/DPEDT/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/DTDT/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/DUDT/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/DVDT/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/PHIS/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/QTR/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/CNV/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/CONVCPT/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/CONVKE/), rc=rc)
call ESMF_FieldBundleAdd(fbundle, (/CONVPHI/), rc=rc)
call ESMF_StateAdd(exportState, fieldbundleList=(/fbundle/), rc=rc)

The link between a State and the Component of interest must be set manually.

call ESMF_AttributeLink(gridcomp, exportState, rc=rc)

There are currently two different formats available for writing the contents of the Attribute packages in an Attribute hierarchy. There is an XML formatted write, which generates an .xml file in the execution directory with the contents of the write. There is also a tab-delimited write which writes to standard out, a file generated in the execution directory with the extension .stdout. Either of the ESMF_AttributeWrite() formats can be called on any of the objects which are capable of manipulating Attributes, but only from objects in an Attribute hierarchy which contain ESMF standard Attribute packages can it be confirmed that any relevant information be written. The ESMF_AttributeWrite() capability is only functional for single-item Attributes at this point, it will be more robust in future releases. A flag is used to specify which format to write, the default is tab-delimited.

call ESMF_AttributeWrite(gridcomp,convESMF,purpGen, &
attwriteflag=ESMF_ATTWRITE_XML,rc=rc)

call ESMF_AttributeWrite(gridcomp,convESMF,purpGen,rc=rc)

38.7.3 Custom Attribute package

This example illustrates how to create a user-defined, custom Attribute package. The package is created on a gridded Component with three custom Attributes.

We must construct the ESMF gridded Component object that will be responsible for the custom Attribute package we will be manipulating.

```plaintext
if (petCount<4) then
   gridcomp = ESMF_GridCompCreate(name="gridded_comp_ex3", &
   petList=(/0/), rc=rc)
else
   gridcomp = ESMF_GridCompCreate(name="gridded_comp_ex3", &
   petList=(/0,1,2,3/), rc=rc)
endif
```

Now we can add a custom Attribute package to the gridded Component object.

```plaintext
customConv = 'CustomConvention'
customPurp = 'CustomPurpose'
customAttrList(1) = 'CustomAttrName1'
customAttrList(2) = 'CustomAttrName2'
```
customAttrList(3) = 'CustomAttrName3'
call ESMF_AttributeAdd(gridcomp, convention=customConv, &
purpose=customPurp, attrList=customAttrList, rc=rc)

We must set the Attribute values of our custom Attribute package.

call ESMF_AttributeSet(gridcomp, 'CustomAttrName1', 'CustomAttrValue1', &
convention=customConv, purpose=customPurp, rc=rc)
call ESMF_AttributeSet(gridcomp, 'CustomAttrName2', 'CustomAttrValue2', &
convention=customConv, purpose=customPurp, rc=rc)
call ESMF_AttributeSet(gridcomp, 'CustomAttrName3', 'CustomAttrValue3', &
convention=customConv, purpose=customPurp, rc=rc)

Write out the contents of our custom Attribute package to an XML file, which is generated with a .xml file extension in the execution directory.

call ESMF_AttributeWrite(gridcomp,customConv,customPurp, &
attwriteflag=ESMF_ATTWRITE_XML,rc=rc)

38.7.4 Updating Attributes in a distributed environment

This advanced example illustrates the proper methods of Attribute manipulation in a distributed environment to ensure consistency of metadata across the VM. This example is much more complicated than the previous two because we will be following the flow of control of a typical model run with two gridded Components and one coupling Component. We will start out in the application driver, declaring Components, States, and the routines used to initialize, run and finalize the user’s model Components. Then we will follow the control flow into the actual Component level through initialize, run, and finalize examining how Attributes are used to organize the metadata.

This example follows a simple user model with two gridded Components and one coupling Component. The initialize routines are used to set up the application data and the run routines are used to manipulate the data. Accordingly, most of the Attribute manipulation will take place in the initialize phase of each of the three Components. The two gridded Components will be running on exclusive pieces of the VM and the coupler Component will encompass the entire VM so that it can handle the Attribute communications.

The control flow of this example will start in the application driver, after which it will complete three cycles through the three Components. The first cycle will be through the initialize routines, from the first gridded Component to the second gridded Component to the coupler Component. The second cycle will go through the run routines, from the
first gridded Component to the coupler Component to the second Gridded component. The third cycle will be through the finalize routines in the same order as the first cycle.

In the application driver, we must now construct some ESMF objects, such as the gridded Components, the coupler Component, and the States. This is also where it is determined which subsets of the PETs of the VM the Components will be using to run their initialize, run, and finalize routines.

```python
gridcomp1 = ESMF_GridCompCreate(name="gridcomp1", &
    petList=(/0,1/), rc=rc)

gridcomp2 = ESMF_GridCompCreate(name="gridcomp2", &
    petList=(/2,3/), rc=rc)

cplcomp = ESMF_CplCompCreate(name="cplcomp", &
    petList=(/0,1,2,3/), rc=rc)
```

Before the individual components are initialized, run, and finalized Attributes should be set at the Component level. Here we are going to use the ESG Attribute package on the first gridded Component. The Attribute package is added, and then each of the Attributes is set. The Attribute hierarchy of the Component is then linked to the Attribute hierarchy of the export State in a manual fashion.

```python
convESMF = 'ESMF'
purpGen = 'General'
call ESMF_AttributeAdd(gridcomp1, &
    convention=convESMF, purpose=purpGen, attpack=attpack, &
    rc=rc)

call ESMF_AttributeSet(gridcomp1, 'Agency', 'NASA', attpack, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'Author', 'Max Suarez', &
    convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'CodingLanguage', &
    'Fortran 90', convention=convESMF, purpose=purpGen, rc=rc)
```
call ESMF_AttributeSet(gridcomp1, 'Discipline', &
   'Atmosphere', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'ComponentLongName', &
   'Goddard Earth Observing System Version 5 Finite Volume Dynamical Core', &
   convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'ModelComponentFramework', &
   'ESMF', &
   convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'ComponentShortName', &
   'GEOS-5 FV dynamical core', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'PhysicalDomain', &
   'Earth system', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeSet(gridcomp1, 'Version', &
   'GEOSagcm-EROS-beta7p12', convention=convESMF, purpose=purpGen, rc=rc)

call ESMF_AttributeLink(gridcomp1, c1exp, rc=rc)

Now the individual Components will be run. First we will initialize the two gridded Components, then we will initialize the coupler Component. During each of these Component initialize routines Attribute packages will be added, and the Attributes set. The Attribute hierarchies will also be linked. As the gridded Components will be running on exclusive portions of the VM, the Attributes will need to be made available across the VM using an ESMF_StateReconcile() call in the coupler Component. The majority of the work with Attributes will take place in this portion of the model run, as metadata rarely needs to be changed during run time.

What follows are the calls from the driver code that run the initialize, run, and finalize routines for each of the Components. After these calls we will step through the first cycle as explained in the introduction, through the initialize routines of gridded Component 1 to gridded Component 2 to the coupler Component.

call ESMF_GridCompInitialize(gridcomp1, exportState=c1exp, rc=rc)
call ESMF_GridCompInitialize(gridcomp2, importState=c2imp, rc=rc)
call ESMF_CplCompInitialize(cplcomp, importState=c1exp, &
   exportState=c2imp, rc=rc)
call ESMF_GridCompRun(gridcomp1, exportState=c1exp, rc=rc)

call ESMF_CplCompRun(cplcomp, importState=c1exp, &
    exportState=c2imp, userRc=urc, rc=rc)

call ESMF_GridCompRun(gridcomp2, importState=c2imp, rc=rc)

call ESMF_GridCompFinalize(gridcomp1, exportState=c1exp, rc=rc)

call ESMF_GridCompFinalize(gridcomp2, importState=c2imp, rc=rc)

call ESMF_CplCompFinalize(cplcomp, importState=c1exp, &
    exportState=c2imp, rc=rc)

In the first gridded Component initialize routine we need to create some Attribute packages and set all of the Attributes. These Attributes will be attached to realistic Fields, containing a Grid, which are contained in a FieldBundle. The first thing to do is declare variables and make the Grid.

type(ESMF_AttPack) :: attpack
    type(ESMF_VM) :: vm
    integer :: petCount, status, myPet
    character(ESMF_MAXSTR) :: name1,name2,name3,name4,value1,value2, &
        value3,value4,convESMF,purpGen,convCC
    type(ESMF_ArraySpec) :: arrayspec
    type(ESMF_Grid) :: grid
    type(ESMF_Field) :: DPEDT,DTDT,DUDT,DVDT,PHIS,QTR,CNV,CONVCPT, &
        CONVKE,CONVPHI
    type(ESMF_FieldBundle) :: fieldbundle
    character(ESMF_MAXSTR),dimension(2) :: attrList
    
rc = ESMF_SUCCESS

call ESMF_GridCompGet(comp, vm=vm, rc=status)
call ESMF_VMGet(vm, petCount=petCount, localPet=myPet, rc=status)
call ESMF_ArraySpecSet(arrayspec, typekind=ESMF_TYPEKIND_R8, rank=2, &
grid = ESMF_GridCreateNoPeriDim(minIndex=(/1,1/), maxIndex=(/100,150/), &
reg Decomp=(/1,petCount/), &
gridEdgeLWidth=(/0,0/), gridEdgeUWidth=(/0,0/), &
indexflag=ESMF_INDEX_GLOBAL, rc=rc)

At this point the Fields will need to have Attribute packages attached to them, and the Attributes will be set with appropriate values.

convCC = 'CustomConvention'
convESMF = 'ESMF'
purpGen = 'General'
name1 = 'ShortName'
name2 = 'StandardName'
name3 = 'LongName'
name4 = 'Units'

value1 = 'DPEDT'
value2 = 'tendency_of_air_pressure'
value3 = 'Edge pressure tendency'
value4 = 'Pa s-1'

DPEDT = ESMF_FieldCreate(grid, arrayspec=arrayspec, &
    staggerloc=ESMF_STAGGERLOC_CENTER, rc=status)
call ESMF_AttributeAdd(DPEDT, convention=convESMF, purpose=purpGen, &
    attpack=attpack, rc=status)
call ESMF_AttributeSet(DPEDT, name=name1, value=value1, attpack=attpack, rc=status)
call ESMF_AttributeSet(DPEDT, name=name2, value=value2, attpack=attpack, rc=status)
call ESMF_AttributeSet(DPEDT, name=name3, value=value3, attpack=attpack, rc=status)
call ESMF_AttributeSet(DPEDT, name=name4, value=value4, attpack=attpack, rc=status)

... and so on for the other 9 Fields.

Now the Fields will be added to the FieldBundle, at which point the Attribute hierarchies of the Fields will also be attached to the Attribute hierarchy of the FieldBundle. After that, the FieldBundle will be attached to the export State, again at which time the Attribute hierarchy of the FieldBundle will be attached to the Attribute hierarchy of the export State.

fieldbundle = ESMF_FieldBundleCreate(name="fieldbundle", rc=status)
call ESMF_FieldBundleSet(fieldbundle, grid=grid, rc=status)

call ESMF_FieldBundleAdd(fieldbundle, (/DPEDT/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/DTDT/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/DUDT/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/DVDT/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/PHIS/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/QTR/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/CNV/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/CONVCP/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/CONVKE/), rc=status)
call ESMF_FieldBundleAdd(fieldbundle, (/CONVPHI/), rc=status)
At this point, the driver of the model run will transfer control to the initialize phase of the second gridded Component.

In the second gridded Component initialize routine we don’t have anything to do. The data that was created in the initialize routine of the first gridded Component will be passed to this Component through the coupler Component. The data will not be used in this Component until the run phase of the model. So now the application driver transfers control to the initialize phase of the coupler Component.

In the coupler Component initialize routine all that is required is to ensure consistent data across the VM. The data created in the first gridded Component on one set of the PETs in the VM is intended to be read and manipulated by the second gridded Component which runs on an exclusive set of the PETs of the VM for this application. We need to first make that data consistent across the entire VM with the ESMF_StateReconcile() call. This State level call handles both the data – Fields and FieldBundles, and the metadata – Attribute and Attribute packages. There is a flag in this call to allow the user to specify whether they want the metadata to be reconciled or not.

At this point, the driver of the model run will transfer control to the run phase of the first gridded Component.

In the run phase of the first gridded Component is typically where the data contained in the Fields is manipulated. For this simple example we will do no actual data manipulation because all we are interested in at this point is the metadata. What we will do is add a nested Attribute package inside the currently existing Attribute package on each Field. We will also change the value of one of the Attributes in the original Attribute package, and remove another of the Attributes from the original Attribute package on each of the Fields. The first thing is to declare variables and get the Component, VM, State, and FieldBundle.

```fortran
  type(ESMF_VM) :: vm

  rc = ESMF_SUCCESS

  call ESMF_CplCompGet(comp, vm=vm, rc=rc)
  call ESMF_StateReconcile(importState, vm=vm, &
                            attreconflag=ESMF_ATTRECONCILE_ON, rc=rc)
  call ESMF_StateReconcile(exportState, vm=vm, &
                            attreconflag=ESMF_ATTRECONCILE_ON, rc=rc)
```

At this point, the driver of the model run will transfer control to the run phase of the first gridded Component.

In the run phase of the first gridded Component is typically where the data contained in the Fields is manipulated. For this simple example we will do no actual data manipulation because all we are interested in at this point is the metadata. What we will do is add a nested Attribute package inside the currently existing Attribute package on each Field. We will also change the value of one of the Attributes in the original Attribute package, and remove another of the Attributes from the original Attribute package on each of the Fields. The first thing is to declare variables and get the Component, VM, State, and FieldBundle.

```fortran
type(ESMF_AttPack) :: attpack, attpackGen
type(ESMF_VM) :: vm
integer :: petCount, status, myPet, k
character(ESMF_MAXSTR) :: name2,value2,convESMF,purpGen,purp2,name3
character(ESMF_MAXSTR),dimension(2) :: attrList
type(ESMF_Field) :: field(10)
type(ESMF_FieldBundle) :: fieldbundle
type(ESMF_Grid) :: grid

rc = ESMF_SUCCESS

convESMF = 'ESMF'
purpGen = 'General'
name2 = 'StandardName'
value2 = 'default_standard_name'
name3 = 'LongName'
```
purp2 = 'Extended'
attrList(1) = 'Coordinates'
attrList(2) = 'Mask'

call ESMF_GridCompGet(comp, vm=vm, rc=status)
call ESMF_VMGet(vm, petCount=petCount, localPet=myPet, rc=status)
call ESMF_StateGet(exportState, "fieldbundle", fieldbundle, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_FieldBundleGet(fieldbundle, grid=grid, rc=rc)
if (rc .ne. ESMF_SUCCESS) return

At this point we will extract each of the Fields in the FieldBundle in turn and change the value of one Attribute in
the original Attribute package, add a nested Attribute package, and delete one other of the Attributes in the original
Attribute package. These three changes represent, respectively, a value change and two structural changes to the
Attribute hierarchy during run time, which must be reconciled across the VM before the second gridded Component
can be allowed to further manipulate the Attribute hierarchy.

call ESMF_FieldBundleGet(fieldbundle, fieldList=field, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
do k = 1, 10
call ESMF_AttributeGetAttPack(field(k), convESMF, purpGen, &
attpack=attpackGen, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_AttributeSet(field(k), name=name2, value=value2, &
attpack=attpackGen, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_AttributeAdd(field(k), attrList=attrList, &
convention=convESMF, purpose=purp2, &
nestConvention=convESMF, nestPurpose=purpGen, &
attpack=attpack, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_AttributeSet(field(k), name='Coordinates', value='Latlon', &
attpack=attpack, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_AttributeSet(field(k), name='Mask', value='Yes', &
attpack=attpack, rc=rc)
if (rc .ne. ESMF_SUCCESS) return
call ESMF_AttributeRemove(field(k), name=name3, &
attpack=attpackGen, rc=status)
if (rc .ne. ESMF_SUCCESS) return
endo

At this point, the driver of the model run will transfer control to the run phase of the coupler Component.

In the run phase of the coupler Component we must now ensure that the entire VM again has a consistent view of the
Attribute hierarchy. This is different from the communication done in the initialize phase of the model run because the
only structural change that has occurred is in the Attribute hierarchy. Therefore an ESMF_AttributeUpdate() call
can be used at this point to reconcile these changes. It should be noted that the ESMF_AttributeUpdate() call
will reconcile value changes to the Attribute hierarchy as well as structural changes.

The first thing to do is to retrieve the Component, VM, and States. Then ESMF_AttributeUpdate() will be
called on the import State to accomplish a VM wide communication. Afterwards, the Attribute hierarchy can be
transfered, in a local sense, from the import State to the export State using an ESMF_AttributeCopy() call.
At this point the entire VM has a consistent view of the Attribute hierarchy that was recently modified during run time in the first gridded component and the driver of the model run will transfer control to the run phase of the second gridded Component.

In the run phase of the second gridded Component is normally where a user model would again manipulate the data it was given. In this simple example we are only dealing with the metadata, which has already been ensured for consistency across the VM, including the exclusive piece of which is being used in this Component. Therefore we are free to use the metadata as we wish, considering only that any changes we make to it during run time will have to first be reconciled before other parts of the VM can use them. However, this is not our concern at this point because we will now explore the capabilities of ESMF_AttributeWrite().

First we will get the Component and VM. Then we will write out the Attribute hierarchy to an .xml file, after which we will write out the Attribute hierarchy to a more reader friendly tab-delimited format. Both of these write calls will output their respective data into files in the execution directory, in either a .xml or .stdout file.
At this point the driver of the model run would normally transfer control to the finalize phase of the first gridded Component. However, there is not much of interest as far as metadata is concerned in this portion of the model run. So with that we will conclude this example.

38.7.5 Accessing object information through Attribute

This example demonstrates the ability to access object information through the Attribute class. This capability is enabled only in the Grid class at this point. Internal Grid information is retrieved through the ESMF_AttributeGet() interface by specifying the name as a character string holding the keyword of the desired piece of Grid information. Information that requires input arguments is retrieved by specifying the input argument in a character array.

Some examples of this capability are given in this section. The first shows how to get the name of a Grid, and the second shows how to get a more complex parameter which requires inputs. First, we must initialize ESMF, declare some variables, and create a Grid:

```fortran
! Use ESMF framework module
use ESMF
use ESMF_TestMod
implicit none

! Local variables
integer :: rc, finalrc, petCount, localPet, result
type(ESMF_VM) :: vm
type(ESMF_Grid) :: grid
type(ESMF_DistGrid) :: distgrid
character(ESMF_MAXSTR) :: name
character(ESMF_MAXSTR),dimension(3) :: inputList
integer(ESMF_KIND_I4) :: exclusiveLBound(2), exclusiveUBound(2)
integer(ESMF_KIND_I4) :: exclusiveCount(2)
character(ESMF_MAXSTR) :: testname
character(ESMF_MAXSTR) :: failMsg

! initialize ESMF
finalrc = ESMF_SUCCESS
call ESMF_Initialize(vm=vm, &
  defaultlogfilename="AttributeInternalInfoEx.Log", &
  logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

distgrid=ESMF_DistGridCreate(minIndex=(/1,1/),maxIndex=(/10,10/), rc=rc)

grid=ESMF_GridCreate(distgrid=distgrid, &
  coordTypeKind=ESMF_TYPEKIND_I4, &
  name="AttributeTestGrid", rc=rc)
```

This first call shows how to retrieve the name of a Grid. The return value is a character string in this case, which must be provided as the argument to 'value'. The 'name' of the Attribute is specified as a character string whose
value is the keyword of the piece of Grid information to retrieve preceded by a special tag. This tag, 'ESMF:', tells
the ESMF_AttributeGet() routine that it should be looking for class information, rather than an Attribute that was
previously created with the ESMF_AttributeSet() call.

call ESMF_AttributeGet(grid, name="ESMF:name", value=name, rc=rc)

This second call demonstrates how to retrieve the exclusiveCount from a Grid. As before, the 'name' of the Attribute
is specified as the keyword of the information to retrieve, preceded by the 'ESMF:' tag. The value is an integer
array, which must be allocated to a sufficient size to hold all of the requested information. The exclusiveCount of a
Grid requires three pieces of input information: localDe, itemflag, and staggerloc. These are specified in an array of
character strings. The name of the input parameter is separated from the value by a ':'.

inputList(:) = ''
inputList(1) = 'localDe:0'
inputList(2) = 'itemflag:ESMF_GRIDITEM_MASK'
inputList(3) = 'staggerloc:ESMF_STAGGERLOC_CENTER'
call ESMF_AttributeGet(grid, name="ESMF:exclusiveCount", 
    valueList=exclusiveCount, inputList=inputList, rc=rc)

That all there is to it! Now we just have to Finalize ESMF:

call ESMF_Finalize(rc=rc)

38.7.6 CIM Attribute packages

This example illustrates the use of the Metafor CIM Attribute packages, supplied by ESMF, to create an Attribute
hierarchy on an ESMF object tree. Gridded, coupler and science Components are used together with a State and a
realistic Field to create a simple ESMF object tree. CIM Attributes packages are created on the Components and Field,
and then the individual Attributes within the packages are populated with values. Finally, all the Attributes are written
to a CIM-formatted XML file. For a more comprehensive example, see the ESMF_AttributeCIM system test.

! Use ESMF framework module
use ESMF
use ESMF_TestMod
implicit none

! Local variables
integer :: rc, finalrc, petCount, localPet, result
type(ESMF_AttPack) :: attpack
type(ESMF_VM) :: vm
type(ESMF_Field) :: ozone
type(ESMF_State) :: exportState
type(ESMF_CplComp) :: cplcomp
type(ESMF_GridComp) :: gridcomp
type(ESMF_SciComp) :: scicomp
character(ESMF_MAXSTR) :: convCIM, purpComp, purpProp, purpSci
character(ESMF_MAXSTR) :: purpField, purpPlatform
character(ESMF_MAXSTR) :: convISO, purpRP, purpCitation
character(ESMF_MAXSTR), dimension(2) :: compPropAtt
character(ESMF_MAXSTR), dimension(2) :: rad_sciPropAtt
character(ESMF_MAXSTR) :: testname
character(ESMF_MAXSTR) :: failMsg

! initialize ESMF
finalrc = ESMF_SUCCESS
call ESMF_Initialize(vm=vm, defaultlogfilename="AttributeCIMEx.Log", &
  logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

! get the vm
call ESMF_VMGet(vm, petCount=petCount, localPet=localPet, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

Create the ESMF objects that will hold the CIM Attributes. These objects include all three Component types (coupler, gridded, and science Components) as well as a State, and a Field. In this example we are constructing empty Fields without an underlying Grid.

! Create top-level Coupler Component
cplcomp = ESMF_CplCompCreate(name="coupler_component", &
  petList=(/0/), rc=rc)

! Create Gridded Component as a child of the Coupler Component
gridcomp = ESMF_GridCompCreate(name="gridded_component", &
  petList=(/0/), rc=rc)
call ESMF_AttributeLink(cplcomp, gridcomp, rc=rc)

! Create Science Component as a child of the Gridded Component
scicomp = ESMF_SciCompCreate(name="science_component", rc=rc)
call ESMF_AttributeLink(gridcomp, scicomp, rc=rc)

! Create State
exportState = ESMF_StateCreate(name="exportState", &
  stateintent=ESMF_STATEINTENT_EXPORT, rc=rc)
! Create Field
ozone = ESMF_FieldEmptyCreate(name='ozone', rc=rc)

convCIM = 'CIM 1.5'
purpComp = 'ModelComp'
purpProp = 'CompProp'
purpSci = 'SciProp'
purpField = 'Inputs'
purpPlatform = 'Platform'

convISO = 'ISO 19115'
purpRP = 'RespParty'
purpCitation = 'Citation'

Add CIM Component package and Attributes to the Coupler Component.

call ESMF_AttributeAdd(cplcomp, &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, "ShortName", "Driver", &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, "LongName", &
    "Model Driver", &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, "ModelType", &
    "climate", &
    convention=convCIM, purpose=purpComp, rc=rc)

! Simulation run attributes

call ESMF_AttributeSet(cplcomp, 'SimulationShortName', &
    'SMS.f09_g16.X.hector', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, 'SimulationLongName', &
    'EarthSys - Earth System Modeling Framework Earth System Model 1.0', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, 'SimulationRationale', &
    'EarthSys-ESMF simulation run in repsect to CMIP5 core experiment 1.1 ()', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, 'SimulationStartDate', &
    '1960-01-01T00:00:00Z', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(cplcomp, 'SimulationDuration', 'P10Y', &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeSet(cplcomp, &
    'SimulationNumberOfProcessingElements', '16', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeGetAttPack(cplcomp, convCIM, purpPlatform, &
    attpack=attpack, rc=rc)

call ESMF_AttributeSet(cplcomp, 'MachineName', 'HECToR', &
    convention=convCIM, purpose=purpPlatform, rc=rc)

Now add CIM Attribute packages and Attributes to the Gridded Component and Field. Also, add a CIM Component Properties package, to contain two custom attributes.

! Add CIM Attribute package to the gridded Component
call ESMF_AttributeAdd(gridcomp, convention=convCIM, &
    purpose=purpComp, rc=rc)

! Specify the gridded Component to have a Component Properties
! package with two custom attributes, with user-specified names
compPropAtt(1) = 'SimulationType'
compPropAtt(2) = 'SimulationURL'
call ESMF_AttributeAdd(gridcomp, convention=convCIM, purpose=purpProp, &
    attrList=compPropAtt, rc=rc)

! Add CIM Attribute package to the Field
call ESMF_AttributeAdd(ozone, convention=convCIM, purpose=purpField, &
    rc=rc)

The standard Attribute package supplied by ESMF for a CIM Component contains several Attributes, grouped into sub-packages. These Attributes conform to the CIM convention as defined by Metafor and their values are set individually.

! Top-level model component attributes, set on gridded component
! call ESMF_AttributeSet(gridcomp, 'ShortName', 'EarthSys_Atmos', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'LongName', &
    'Earth System High Resolution Global Atmosphere Model', &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeSet(gridcomp, 'Description', &
    'EarthSys brings together expertise from the global community in a concerted effort to develop coupled climate models with increased horizontal resolutions. Increasing the horizontal resolution of coupled climate models will allow us to capture climate processes and weather systems in much greater detail.', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'Version', '2.0', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'ReleaseDate', '2009-01-01T00:00:00Z', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'ModelType', 'aerosol', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'URL', &
    'www.earthsys.org', convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MetadataVersion', '1.1', &
    convention=convCIM, purpose=purpComp, rc=rc)

! Document genealogy
call ESMF_AttributeSet(gridcomp, 'PreviousVersion', &
    'EarthSys1 Atmosphere', &
    convention=convCIM, purpose=purpComp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'PreviousVersionDescription', &
    'Horizontal resolution increased to 1.20 x 0.80 degrees; Timestep reduced from 30 minutes to 15 minutes.', &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeGetAttPack(gridcomp, convCIM, purpPlatform, &
attpack=attpack, rc=rc)

! Platform description attributes
call ESMF_AttributeSet(gridcomp, 'CompilerName', 'Pathscale', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'CompilerVersion', '3.0', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineName', 'HECToR', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineDescription', &
'HECToR (Phase 2a) is currently an integrated system known ' // &
'as Rainier, which includes a scalar MPP XT4 system, a vector ' // &
'system known as BlackWidow, and storage systems.', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineSystem', 'Parallel', &
convention=convCIM, purpose=purpPlatform, rc=rc)
call ESMF_AttributeSet(gridcomp, 'MachineOperatingSystem', 'Unicos', &
convention=convCIM, purpose=purpPlatform, rc=rc)
call ESMF_AttributeSet(gridcomp, 'MachineVendor', 'Cray Inc', &
convention=convCIM, purpose=purpPlatform, rc=rc)
call ESMF_AttributeSet(gridcomp, 'MachineInterconnectType', &
'Cray Interconnect', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineMaximumProcessors', '22656', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineCoresPerProcessor', '4', &
convention=convCIM, purpose=purpPlatform, rc=rc)

call ESMF_AttributeSet(gridcomp, 'MachineProcessorType', 'AMD X86_64', &
convention=convCIM, purpose=purpPlatform, rc=rc)
call ESMF_AttributeGetAttPack(gridcomp, convCIM, purpProp, &
attpack=attpack, rc=rc)

! Component Properties: custom attributes

call ESMF_AttributeSet(gridcomp, 'SimulationType', 'branch', &
    convention=convCIM, purpose=purpProp, rc=rc)

call ESMF_AttributeSet(gridcomp, 'SimulationURL', &
    'http://earthsys.org/simulations', &
    convention=convCIM, purpose=purpProp, rc=rc)

Set the attribute values of the Responsible Party sub-package, created above for the gridded Component in the ESMF_AttributeAdd(gridcomp,...) call.

call ESMF_AttributeGetAttPack(gridcomp, convISO, purpRP, &
attpack=attpack, rc=rc)

! Responsible party attributes (for Principal Investigator)
call ESMF_AttributeSet(gridcomp, 'Name', 'John Doe', &
    convention=convISO, purpose=purpRP, rc=rc)
call ESMF_AttributeSet(gridcomp, 'Abbreviation', 'JD', &
    convention=convISO, purpose=purpRP, rc=rc)
call ESMF_AttributeSet(gridcomp, 'PhysicalAddress', &
    'Department of Meteorology, University of ABC', &
    convention=convISO, purpose=purpRP, rc=rc)
call ESMF_AttributeSet(gridcomp, 'EmailAddress', &
    'john.doe@earthsys.org', &
    convention=convISO, purpose=purpRP, rc=rc)
call ESMF_AttributeSet(gridcomp, 'ResponsiblePartyRole', 'PI', &
    convention=convISO, purpose=purpRP, rc=rc)

call ESMF_AttributeSet(gridcomp, 'URL', 'www.earthsys.org', &
    convention=convISO, purpose=purpRP, rc=rc)

Set the attribute values of the Citation sub-package, created above for the gridded Component in the ESMF_AttributeAdd(gridcomp,...) call.

call ESMF_AttributeGetAttPack(gridcomp, convISO, purpCitation, &
attpack=attpack, rc=rc)

! Citation attributes
call ESMF_AttributeSet(gridcomp, 'ShortTitle', 'Doe_2009', &
    convention=convISO, purpose=purpCitation, rc=rc)
call ESMF_AttributeSet(gridcomp, 'LongTitle', &
Add Component attributes to the Science Component and then add scientific properties to it.

call ESMF_AttributeAdd(scicomp, &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeSet(scicomp, "ShortName", "AtmosRadiation", &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeSet(scicomp, "LongName", &
    "Atmosphere Radiation", &
    convention=convCIM, purpose=purpComp, rc=rc)
call ESMF_AttributeSet(scicomp, "ModelType", &
    "radiation", &
    convention=convCIM, purpose=purpComp, rc=rc)

rad_sciPropAtt(1) = ‘LongwaveSchemeType’
rad_sciPropAtt(2) = ‘LongwaveSchemeMethod’

call ESMF_AttributeAdd(scicomp, &
    convention=convCIM, purpose=purpSci, &
    attrList=rad_sciPropAtt, rc=rc)
call ESMF_AttributeSet(scicomp, &
    'LongwaveSchemeType', &
    'wide-band model', &
    convention=convCIM, purpose=purpSci, rc=rc)
call ESMF_AttributeSet(scicomp, &
    'LongwaveSchemeMethod', &
    'two-stream', &
    convention=convCIM, purpose=purpSci, rc=rc)

The standard Attribute package currently supplied by ESMF for CIM Fields contains a standard CF-Extended package nested within it.

call ESMF_AttributeGetAttPack(ozone, convCIM, purpField, &
    attpack=attpack, rc=rc)

! ozone CF-Extended Attributes
call ESMF_AttributeSet(ozone, 'ShortName', 'Global_O3_mon', &
    convention=convCIM, purpose=purpField, rc=rc)
call ESMF_AttributeSet(ozone, 'StandardName', 'ozone', &
    convention=convCIM, purpose=purpField, rc=rc)
call ESMF_AttributeSet(ozone, 'LongName', 'ozone', &
    convention=convCIM, purpose=purpField, rc=rc)
call ESMF_AttributeSet(ozone, 'Units', 'unknown', &
    convention=convCIM, purpose=purpField, rc=rc)

! ozone CIM Attributes
call ESMF_AttributeSet(ozone, 'CouplingPurpose', 'Boundary', &
    convention=convCIM, purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'CouplingSource', 'EarthSys_Atmos', &
    convention=convCIM, purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'CouplingTarget', &
    'EarthSys_AtmosDynCore', convention=convCIM, &
    purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'Description', &
    'Global Ozone concentration' // &
    'monitoring in the atmosphere.', &
    convention=convCIM, purpose=purpField, rc=rc)
call ESMF_AttributeSet(ozone, 'SpatialRegriddingMethod', &
    'Conservative-First-Order', &
    convention=convCIM, purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'SpatialRegriddingDimension', '3D', &
    convention=convCIM, purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'Frequency', '15 Minutes', &
    convention=convCIM, purpose=purpField, rc=rc)

call ESMF_AttributeSet(ozone, 'TimeTransformationType', &
    'TimeInterpolation', &
    convention=convCIM, purpose=purpField, rc=rc)

Adding the Field to the State will automatically link the Attribute hierarchies from the State to the Field

! Add the Field directly to the State
call ESMF_StateAdd(exportState, fieldList=(/ozone/), rc=rc)

The Attribute link between a Component and a State must be set manually.

! Link the State to the gridded Component
call ESMF_AttributeLink(gridcomp, exportState, rc=rc)

Write the entire CIM Attribute hierarchy, beginning at the gridded Component (the top), to an XML file formatted to conform to CIM specifications. The CIM output tree structure differs from the internal Attribute hierarchy in that it has all the attributes of the fields within its top-level <modelComponent> record. The filename used, gridded_component.xml, is derived from the name of the gridded Component, given as an input argument in the ESMF_GridCompCreate() call above. The file is written to the examples execution directory.

call ESMF_AttributeWrite(cplcomp, convCIM, purpComp, &
    attwriteflag=ESMF_ATTWRITE_XML, rc=rc)

call ESMF_StateDestroy(exportState, rc=rc)
call ESMF_SciCompDestroy(scicomp, rc=rc)
call ESMF_GridCompDestroy(gridcomp, rc=rc)
call ESMF_CplCompDestroy(cplcomp, rc=rc)

call ESMF_Finalize(rc=rc)

38.7.7  Read an XML file-based ESG Attribute package for a Gridded Component

This example shows how to read an ESG Attribute Package for a Gridded Component from an XML file. The XML file contains Attribute values filled-in by the user. The standard ESG Component Attribute Package is supplied with ESMF and is defined in an XSD file, which is used to validate the XML file. See

ESMF_DIR/src/Superstructure/Component/etc/esmf_gridcomp.xml (Attribute Package values) and
ESMF_DIR/src/Superstructure/Component/etc/esmf_comp.xsd (Attribute Package definition).

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! Get custom "MyAttribute5" from CplComp
call ESMF_AttributeGet(cplcomp, name='MyAttribute5', value=attrValue, &
   rc=rc)

call ESMF_CplCompDestroy(cplcomp, rc=rc)

! finalize ESMF framework
call ESMF_Finalize(rc=rc)

38.8 Restrictions and Future Work

38.8.1 Attributes

- Case insensitive Attribute names, conventions, purposes, and values will be enabled in a future release.

38.8.2 Attribute packages

- A future capability may be to automatically create default object Attribute packages upon ESMF object creation, this is being prototyped with the CIM 1.5.1 grids package in the present release.
- The implementation of Grids is still in flux within the CIM. In particular, this will affect the final appearance of the CIM 1.5.1 grids package in ESMF.
- A CIM Scientific Property Attribute Package will be added. For CMIP5, hundreds of Scientific Properties have been identified. All of these will be added to ESMF.
- The Attribute packages ISO Responsible Party, ISO Citation, and CIM Platform can only be created automatically within a CIM Main component Attribute package. In a future release, it will be possible to create these within other CIM Attribute packages as required, or as separate, standalone packages.

38.8.3 Attribute hierarchies

- The option of "deep" copies of an Attribute hierarchy will be added.

38.8.4 Attribute import and export

- The CIM XML output in this release validates against the official CIM v1.5 release. CIM development is continuing, with further releases expected. ESMF, in its future releases, will conform to these future CIM releases.
- CIM Attribute packages can only be output (to CIM XML); they may be inputtable (via XML) in a future release.
38.9 Design and Implementation Notes

This section covers Attribute memory deallocation, the use of ESMF_AttributeGet(), Attribute package nesting capabilities, issues with Attributes in a distributed environment, and reading/writing of Attributes via XML files. Issues and procedures dealing with Attribute memory deallocation, using ESMF_AttributeGet() to retrieve Attribute lists, and nested Attribute package capabilities are discussed to help avoid misuse. The limitations with Attributes in a distributed environment are also discussed, with an outline of the future work to be done in this area.

38.9.1 Attribute memory deallocation

The Attribute class presents a somewhat different paradigm with respect to memory deallocation than other ESMF objects. The ESMF_AttributeRemove() call can be issued to remove any Attribute from an ESMF object or an Attribute package on an ESMF object. This call is also enabled to remove entire Attribute packages with one call, which would remove any nested Attributes packages as well. The user is not required to remove all Attributes that are used in a model run. The entire Attribute hierarchy will be removed automatically by ESMF, provided the ESMF objects which contain them are properly destroyed.

The decision to remove either an Attribute or an Attribute package is made by calling ESMF_AttributeRemove() with the correct optional arguments. If an Attribute which is not associated with any Attribute package should be removed, then the call must be issued without a convention or purpose argument. If an Attribute in an Attribute package is to be removed, then the call should be issued with all three of name, convention, and purpose. Finally, if an entire Attribute package is to be removed the call should be issued with a convention and purpose, but no Attribute name.

38.9.2 Using ESMF_AttributeGet() to retrieve Attribute lists

The behavior of the ESMF_AttributeGet() routine, when retrieving an Attribute containing a value list, follows a slightly different convention than other similar ESMF routines. This routine requires the input of a Fortran array as a place to store the retrieved values of the Attribute list. If the array that is given is longer that the list of Attribute values, the first part of the array will be filled, leaving the extra space untouched. If, however, the array passed in is shorter than the number of Attribute values, the routine will exit with a return code which is not equal to ESMF_SUCCESS. It is suggested that if it is required by the user to use a Fortran array that is longer than the number of Attribute values returned, only the indices of the array which the user desires to be filled with retrieved Attribute values should be passed into the routine.

Similar behavior is exhibited with the defaultValueList argument in the ESMF_AttributeGet() routine. The difference here is that if the valueList is shorter than the defaultValueList only the appropriate values will be filled in, and the routine will exit without error. Likewise, if the valueList is longer than the defaultValueList then the entire valueList will be populated with the beginning section of the defaultValueList that is given.

38.9.3 Using Attribute package nesting capabilities

There is a recommended practice to organizing metadata conventions when using nested Attribute packages. The most general Attribute packages should always be added first, followed by the more specific ones. For instance, when adding Attribute packages to a Field, it is recommended that the CF convention be added first, followed by the ESMF convention, followed by any additional customized Attribute packages.

At this time there are several ESMF supplied Attribute packages, with a convention of ESMF and a purpose of General. These Attribute packages are generated by calling ESMF_AttributeAdd() with the appropriate convention and
purpose. The ESMF standard Attribute packages can be customized by nesting a custom Attribute package around them; they can also be modified in other ways but this is not suggested practice at this time.

Another consideration when using nested Attribute packages is to remember that when a nested Attribute package is removed every nested Attribute package below the point of removal will also be removed (like pruning a tree branch). Thus, by removing the ESMF Attribute package on a Field, the CF Attribute package contained within it will also be removed.

### 38.9.4 Attributes in a distributed environment

This section discusses the methods of building a consistent view of the metadata across the VM of a model run. To better explain the ESMF capabilities for ensuring the integrity of Attributes in a distributed environment, a small working vocabulary of ESMF Attributes will be presented. Three types of changes to an Attribute hierarchy need to be specified, these are: 1. **link changes** are structural links created when two separate Attribute hierarchies are linked, 2. **structural changes** are changes which occur when Attributes or Attribute packages are added or removed within a single level of an Attribute hierarchy, and 3. **value changes** occur when the value portion of any single Attribute is modified. These definitions will help to describe how ESMF _StateReconcile_() and ESMF _AttributeUpdate_() can be effectively used to ensure a consistent view of the metadata throughout a model run.

The ESMF _StateReconcile_() call is used to create a consistent view of ESMF objects over the entire VM in the initialization phase of a model run. All Attributes that are attached to an ESMF object contained in the State, i.e. an object that is being reconciled, can also be reconciled. This is done by setting a flag in the ESMF _StateReconcile_() call, see the State documentation for details. This means that, at the conclusion of ESMF _StateReconcile_() there is a one-to-one correspondence between Attribute hierarchies and the ESMF objects they represent. This is the only place where link changes in an Attribute hierarchy can be resolved.

The ESMF _AttributeUpdate_() call can be used any time during the run phase of a model to insure that either structural or value changes made to an Attribute hierarchy on a subset of the VM are consistently represented across the remainder of the VM. At this time, link changes cannot be resolved by ESMF _AttributeUpdate_() as this would represent a departure from the one-to-one correspondence between the Attribute hierarchy and the ESMF objects it represents. This means that ESMF _AttributeUpdate_() will only work if it is called after ESMF _StateReconcile_() when link changes have been made.

ESMF _AttributeUpdate_() is similar to ESMF _StateReconcile_() in that it must be called from a location that has a view of the entire VM across which to update the Attribute hierarchy, such as a coupler Component. The main difference is that ESMF _AttributeUpdate_() operates only on the underlying Attribute hierarchy of the given ESMF object. The Attribute hierarchy may be updated as many times as necessary, this call is much more efficient than ESMF _StateReconcile_() for this reason.

The specification of a list of PETs that are to be used as the basis for the update is a key feature of this interface. This allows a many-to-many communication, as well as the direct specification of which PETs are to be updated and which are to be used as the "real" values. The information is basically transported from the Attributes on the PETs specified in the rootList to their counterparts on the PETs which are not specified in the rootList. This means that care must be taken to ensure that the data on the PETs in the rootList is consistent.

One caveat with this routine is that upon completion the destination PETs will have all of the missing Attributes from the source PETs, but this is not true the other way around. This basically boils down to the fact that the end product of calling ESMF _AttributeUpdate_() is not the union of the Attributes on both source and destination PETs. This can be achieved, however, by calling ESMF _AttributeUpdate_() twice, once from source to destination, and then again from destination to source.
38.9.5 Writing Attribute packages to file

The ESMF_AttributeWrite() interface is in limited form at the present time, as it can only be used reliably on the ESMF standard Attribute packages. Chances are that it will perform as expected for most Attribute packages, but for now it is only guaranteed for the ESMF standard Attribute packages. This routine is also not yet enabled to handle multi-valued Attributes. One thing to remember when using this interface is that if you are writing an Attribute package that contains nested Attribute packages then all Attribute nested below the top level Attribute package will be written.

38.9.6 Copying Attribute hierarchies

The ability to copy an Attribute hierarchy is limited at this time. The ESMF_AttributeCopy() routine can be used to locally copy an Attribute hierarchy between two States or Components. It is important to note that this is a local copy, and no inter-PET communication is carried out. Another thing to note is that when this functionality is based on a reference copy any further changes made to some portions of the original Attribute hierarchy will also affect the new Attribute hierarchy.

There are two flags in the ESMF_AttributeCopy() routine which specify which type of copy is desired. At this point there are only two different varieties of Attribute hierarchy copies available. One of the requires the ESMF_Copy_Flag to be set to ESMF_COPY_VALUE and the ESMF_AttTreeFlag to be set to ESMF_ATTTREE_OFF. This does a copy of only the first level of an Attribute hierarchy, by value.

The second available copy can be applied by setting the ESMF_Copy_Flag to ESMF_COPY_ALIAS and the ESMF_AttTreeFlag to ESMF_ATTTREE_ON. This copy is more of a hybrid approach of reference and value copies. In this case the Attributes which belong to the object being copied are actually copied in full (by value), while the Attributes which are linked to the object being copied are referenced by a pointer (by reference). This means that after copying an Attribute hierarchy from ESMF object A to ESMF object B with this approach, the changes made to the lower portion of either A or B’s Attribute hierarchy will be reflected on both object A and object B.

38.9.7 Reading and writing Attributes from XML files

The Xerces C++ library, v3.1.0 or better, is used to read XML files. More specifically, the SAX2 API is currently used, although future releases may also use the DOM API. The Xerces C++ website is http://xerces.apache.org/xerces-c/. For more details, see the "ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, Xerces". Also please see the section on Attribute I/O, Writing Attribute XML files is performed with the standard C++ output file stream facility.

38.10 Object Model

Each Attribute contains a name-value pair in which the value can be any of several numeric, character, and logical types. Each value type is implemented as a vector, and can hold one or several values. The available ESMF Attribute value types include:

- ESMF_TYPEKIND_I4
- ESMF_TYPEKIND_I8
- ESMF_TYPEKIND_R4
- ESMF_TYPEKIND_R8
• ESMF_TYPEKIND_Logical
• ESMF_TYPEKIND_Character

The other members of the Attribute class can be seen in Figure 23 below, which shows a UML representation of the ESMF Attribute class.

In addition to a name, all Attributes within an Attribute package are identified by a convention, purpose, and the ESMF object type with which they are associated. These are additional strings that are initialized as empty until specified.

Also, all Attributes contain three vectors of pointers to other Attributes, which are empty until specified otherwise. These vectors of Attribute pointers hold the Attributes, Attribute packages, and Attribute links. This feature is what allows the Attribute class to self assemble complex structures for representing and organizing the metadata of an ESMF object hierarchy.

For a more detailed view of how Attribute packages and hierarchies are formed, see Figures 24 and 25 respectively.

38.11 Class API

38.11.1 ESMF_AttributeAdd - Add an ESMF standard Attribute package using a specification list

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttrAddPackStdSL(<object>, specList, &
attpack, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: specList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_AttPack), intent(inout), optional :: attpack
integer, intent(out), optional :: rc

DESCRIPTION:

Add an ESMF standard Attribute package. See Section[38.2] for a description of Attribute packages.
Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_Field), intent(inout) :: field
type(ESMF_Grid), intent(inout) :: grid
type(ESMF_State), intent(inout) :: state

The arguments are:

<object> An ESMF object
specList A character list of values which identify the Attribute package, such as convention, purpose, and instance-name
[attpack] An optional handle to the Attribute package that is to be created
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.2 ESMF_AttributeAdd - Add a custom Attribute package or modify an existing Attribute package using a specification list

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttAddPackCstSL(<object>, specList, & attrList, count, attpack, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: specList(:)
character (len = *), intent(in) :: attrList(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: count
type(ESMF_AttPack), intent(inout), optional :: attpack
integer, intent(out), optional :: rc

DESCRIPTION:

Add a custom Attribute package to <object>. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_DistGrid), intent(inout) :: distgrid
type(ESMF_Field), intent(inout) :: field
type(ESMF_FieldBundle), intent(inout) :: fieldbundle
type(ESMF_Grid), intent(inout) :: grid
type(ESMF_State), intent(inout) :: state

The arguments are:

<object> An ESMF object
specList A character list of values which identify the Attribute package, such as convention, purpose, and instance-name
attrList The list of Attribute names to specify the custom Attribute package
[count] The number of Attributes to add to the custom Attribute package
[attpack] An optional handle to the Attribute package that is to be created
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.3 ESMF_AttributeAdd - Add an ESMF standard Attribute package

INTERFACE:

! Private name; call using ESMF_AttributeAdd() subroutine ESMF_AttAddPackStd(<object>, convention, purpose, attpack, rc)

ARGUMENTS:

<object>, see below for supported values character (len = *), intent(in) :: convention character (len = *), intent(in) :: purpose type(ESMF_AttPack), intent(inout), optional :: attpack integer, intent(out), optional :: rc

DESCRIPTION:

Add an ESMF standard Attribute package. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

- type(ESMF_Array), intent(inout) :: array
- type(ESMF_CplComp), intent(inout) :: comp
- type(ESMF_GridComp), intent(inout) :: comp
- type(ESMF_SciComp), intent(inout) :: comp
- type(ESMF_Field), intent(inout) :: field
- type(ESMF_Grid), intent(inout) :: grid
- type(ESMF_State), intent(inout) :: state

The arguments are:

<object> An ESMF object
convention The convention of the new Attribute package
purpose The purpose of the new Attribute package
[attpack] An optional handle to the Attribute package that is to be created
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.4 ESMF_AttributeAdd - Add an ESMF standard Attribute package containing nested standard Attribute packages

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttAddPackStdN(<object>, convention, purpose, &
nestConvention, nestPurpose, nestAttPackInstanceCountList, &
nestAttPackInstanceNameList, nestCount, &
nestAttPackInstanceNameCount, attpack, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: convention
character (len = *), intent(in) :: purpose
character (len = *), intent(in) :: nestConvention(:)
character (len = *), intent(in) :: nestPurpose(:)
integer, intent(in) :: nestAttPackInstanceCountList(:)
character (len =* ), intent(out) :: nestAttPackInstanceNameList(:)
integer, intent(in), optional :: nestCount
integer, intent(out), optional :: nestAttPackInstanceNameCount
integer, intent(out), optional :: attpack
integer, intent(out), optional :: rc

description:

Add an ESMF standard Attribute package which contains a user-specified number of nested standard Attribute packages. ESMF generates and returns default instance names for the nested Attribute packages. These names can be used later to distinguish among multiple nested Attribute packages of the same type in calls to ESMF_AttributeGet(), ESMF_AttributeSet(), and ESMF_AttributeRemove(). See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_CplComp), intent(inout) :: comp

type(ESMF_GridComp), intent(inout) :: comp

type(ESMF_SciComp), intent(inout) :: comp

The arguments are:

<object> An ESMF object

convention The convention of the new Attribute package

purpose The purpose of the new Attribute package

nestConvention The convention(s) of the standard Attribute package(s) around which to nest the new Attribute package

nestPurpose The purpose(s) of the standard Attribute package(s) around which to nest the new Attribute package
nestAttPackInstanceCountList  The desired number of nested Attribute package instances for each nested (nest-Convention, nestPurpose) package type. Note: if only one of each nested package type is desired, then the ESMF_AttributeAdd() overloaded method ESMF_AttAddPackStd() should be used.

nestAttPackInstanceNameList  The name(s) of the nested Attribute package instances, generated by ESMF, used to distinguish between multiple instances of the same convention and purpose.

[nestCount]  The count of the number of nested Attribute package types to add to the new Attribute package.

[nestAttPackInstanceNameCount]  The number of nested Attribute package instance names.

[attpack]  An optional handle to the Attribute package that is to be created

[rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.5  ESMF_AttributeAdd - Add a custom Attribute package or modify an existing Attribute package

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttAddPackCst(<object>, convention, purpose, &
attrList, count, attpack, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: convention
character (len = *), intent(in) :: purpose
character (len = *), intent(in) :: attrList(:)
integer, intent(in), optional :: count
type(ESMF_AttPack), intent(inout), optional :: attpack
integer, intent(out), optional :: rc

DESCRIPTION:

Add a custom Attribute package to <object>. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_DistGrid), intent(inout) :: distgrid
type(ESMF_Field), intent(inout) :: field
type(ESMF_FieldBundle), intent(inout) :: fieldbundle

type(ESMF_Grid), intent(inout) :: grid

type(ESMF_State), intent(inout) :: state

The arguments are:

<object>   An ESMF object

convention  The convention of the Attribute package

purpose     The purpose of the Attribute package

attrList    The list of Attribute names to specify the custom Attribute package

[count]    The number of Attributes to add to the custom Attribute package

[attpack]  An optional handle to the Attribute package that is to be created

[rc]       Return code; equals ESMF_SUCCESS if there are no errors

38.11.6   ESMF_AttributeAdd - Add a custom Attribute package with nested Attribute packages or modify an existing Attribute package

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttAddPackCstN(<object>, convention, purpose, &
attrList, count, nestConvention, nestPurpose, nestCount, attpack, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: convention
character (len = *), intent(in) :: purpose
character (len = *), intent(in), optional :: attrList(:)
integer, intent(in), optional :: count
character (len = *), intent(in) :: nestConvention(:)
character (len = *), intent(in) :: nestPurpose(:)
integer, intent(in), optional :: nestCount

type(ESMF_AttPack), intent(inout), optional :: attpack

integer, intent(out), optional :: rc

DESCRIPTION:

Add a custom Attribute package, with one or more nested Attribute packages, to <object>. Allows for building full multiple-child Attribute hierarchies (multi-child trees). See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:
The arguments are:

<object> An ESMF object

convention The convention of the Attribute package

purpose The purpose of the Attribute package

[attrList] The list of Attribute names to specify the custom Attribute package

[count] The number of Attributes to add to the custom Attribute package

nestConvention The convention(s) of the Attribute package(s) around which to nest the new Attribute package

nestPurpose The purpose(s) of the Attribute package(s) around which to nest the new Attribute package

[nestCount] The number of nested Attribute packages to add to the custom Attribute package

[attpack] An optional handle to the Attribute package that is to be created

[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.7 ESMF_AttributeAdd - Add a custom Attribute package with a single nested Attribute package, or modify an existing Attribute package

INTERFACE:

! Private name; call using ESMF_AttributeAdd()
subroutine ESMF_AttAddPackCstN1(<object>, convention, purpose, &
attrList, count, nestConvention, nestPurpose, attpack, rc)

ARGUMENTS:

Supported values for <object> are:

- type(ESMF_Array), intent(inout) :: array
- type(ESMF_ArrayBundle), intent(inout) :: arraybundle
- type(ESMF_CplComp), intent(inout) :: comp
- type(ESMF_GridComp), intent(inout) :: comp
- type(ESMF_SciComp), intent(inout) :: comp
- type(ESMF_DistGrid), intent(inout) :: distgrid
- type(ESMF_Field), intent(inout) :: field
- type(ESMF_FieldBundle), intent(inout) :: fieldbundle
- type(ESMF_Grid), intent(inout) :: grid
- type(ESMF_State), intent(inout) :: state

The arguments are:

<object> An ESMF object

convention The convention of the Attribute package

purpose The purpose of the Attribute package

[attrList] The list of Attribute names to specify the custom Attribute package

[count] The number of Attributes to add to the custom Attribute package

nestConvention The convention of the Attribute package around which to nest the new Attribute package

nestPurpose The purpose of the Attribute package around which to nest the new Attribute package

[attpack] An optional handle to the Attribute package that is to be created

[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.8 ESMF_AttributeCopy - Copy an Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeCopy()
subroutine ESMF_AttributeCopy(<object1>, <object2>, copyflag, &
attreeflag, rc)

ARGUMENTS:

<object1>, see below for supported values
<object2>, see below for supported values
type(ESMF_Copy_Flag), intent(in) :: copyflag
type(ESMF_AttTreeFlag), intent(in) :: atttreeflag
integer, intent(out), optional :: rc

DESCRIPTION:

Copy an Attribute hierarchy from <object1> to <object2>.
Supported values for <object1> are:

  type(ESMF_CplComp), intent(in) :: comp1
  type(ESMF_GridComp), intent(in) :: comp1
  type(ESMF_SciComp), intent(in) :: comp1
  type(ESMF_State), intent(in) :: state

Supported values for <object2> are:

  type(ESMF_CplComp), intent(inout) :: comp2
  type(ESMF_GridComp), intent(inout) :: comp2
  type(ESMF_SciComp), intent(inout) :: comp2
  type(ESMF_State), intent(inout) :: state

NOTE: Copies between different ESMF object types are not possible at this time.
The arguments are:

<object1> An ESMF object
<object2> An ESMF object
copyflag A flag to determine if the copy is to be by reference, value, or both. This flag is documented in section 50.11
atttreeflag A flag to determine if the copy is supposed to descend the Attribute hierarchy. This flag is documented in section 38.6.2
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.9  ESMF_AttributeGet - Get an Attribute from an ESMF_AttPack

INTERFACE:

    subroutine ESMF_AttributeGet(<object>, name, attpack, <value> &
    <defaultvalue>, isPresent, rc)

ARGUMENTS:

    <object>, see below for supported values
    character (len = *), intent(in) :: name
    type(ESMF_AttPack), intent(inout) :: attpack
    <value>, see below for supported values
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    <defaultvalue>, see below for supported values
    logical, intent(out), optional :: isPresent
    integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute value from the <object>, or from an Attribute package on the <object>, specified by attpack. Internal information can also be retrieved from Grid objects by prepending 'ESMF:' to the name of the piece of information that is requested. See Section 38.5 for more information on which pieces of Grid data can be retrieved through this interface. A defaultvalue argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

    type(ESMF_Array), intent(in) :: array
    type(ESMF_ArrayBundle), intent(in) :: arraybundle
    type(ESMF_CplComp), intent(in) :: comp
    type(ESMF_GridComp), intent(in) :: comp
    type(ESMF_SciComp), intent(in) :: comp
    type(ESMF_DistGrid), intent(in) :: distgrid
    type(ESMF_Field), intent(in) :: field
    type(ESMF_FieldBundle), intent(in) :: fieldbundle
    type(ESMF_Grid), intent(in) :: grid
    type(ESMF_State), intent(in) :: state

Supported values for <value> are:

    integer(ESMF_KIND_I4), intent(out) :: value
    integer(ESMF_KIND_I8), intent(out) :: value
    real (ESMF_KIND_R4), intent(out) :: value
real (ESMF_KIND_R8), intent(out) :: value
logical, intent(out) :: value
character (len = *), intent(out) :: value

Supported values for <defaultvalue> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultvalue
integer(ESMF_KIND_I8), intent(in), optional :: defaultvalue
real (ESMF_KIND_R4), intent(in), optional :: defaultvalue
real (ESMF_KIND_R8), intent(in), optional :: defaultvalue
logical, intent(in), optional :: defaultvalue
character (len = *), intent(in), optional :: defaultvalue

The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
attpack A handle to the Attribute package
)value The value of the named Attribute
[<defaultvalue>] The default value of the named Attribute
[isPresent] A logical flag to tell if this Attribute is present or not
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.10 ESMF_AttributeGet - Get an Attribute pointing to internal class information from an ESMF_AttPack

INTERFACE:

subroutine ESMF_AttributeGet(<object>, name, attpack, <value>, &
<defaultvalue>, inputList, isPresent, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
type(ESMF_AttPack), intent(inout) :: attpack
'value>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
<defaultvalue>, see below for supported values
character (len = *), intent(in), optional :: inputList(:)
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc
DESCRIPTION:

Return an Attribute value from the <object>, or from an Attribute package on the <object>, specified by attpack. Internal class information can be retrieved by prepending ’ESMF:’ to the name of the piece of information that is requested. See Section 38.5 for more information on this capability. A defaultvalue argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

\[
\text{type(ESMF\_Grid), intent(in)} :: \text{grid}
\]

Supported values for <value> are:

\[
\text{integer(ESMF\_KIND\_I4), intent(out)} :: \text{value}
\]

\[
\text{character (len = *), intent(out)} :: \text{value}
\]

Supported values for <defaultvalue> are:

\[
\text{integer(ESMF\_KIND\_I4), intent(in), optional :: defaultvalue}
\]

\[
\text{character (len = *), intent(in), optional :: defaultvalue}
\]

The arguments are:

\[
<\text{object}>\text{ An ESMF object}
\]

name The name of the Attribute to retrieve

attpack A handle to the Attribute package

<value argument> The value of the named Attribute

[<defaultvalue argument>] The default value of the named Attribute

[inputList] A list of the input parameters required to retrieve internal info

[isPresent] A logical flag to tell if this Attribute is present or not

[rc] Return code; equals ESMF\_SUCCESS if there are no errors

38.11.11  ESMF\_AttributeGet - Get an Attribute from an ESMF\_AttPack

INTERFACE:

\[
\text{subroutine ESMF\_AttributeGet (<object>, name, attpack, <valueList>, \&}<\text{<defaultvalueList>}, \text{itemCount, isPresent, rc})
\]

ARGUMENTS:
<object>, see below for supported values
class (len = *), intent(in) :: name
type(ESMF_AttPack), intent(inout) :: attpack
<valueList>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
<defaultvalueList>, see below for supported values
integer, intent(out), optional :: itemCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute valueList from the <object>, or from an Attribute package on the <object>, specified by attpack. Internal information can also be retrieved from Grid objects by prepending 'ESMF:' to the name of the piece of information that is requested. See Section 38.5 for more information on which pieces of Grid data can be retrieved through this interface. A defaultvalueList list argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Array), intent(in) :: array
type(ESMF_ArrayBundle), intent(in) :: arraybundle
type(ESMF_CplComp), intent(in) :: comp
type(ESMF_GridComp), intent(in) :: comp
type(ESMF_SciComp), intent(in) :: comp
type(ESMF_DistGrid), intent(in) :: distgrid
type(ESMF_Field), intent(in) :: field
type(ESMF_FieldBundle), intent(in) :: fieldbundle
type(ESMF_Grid), intent(in) :: grid
type(ESMF_State), intent(in) :: state

Supported values for <valueList> are:

integer(ESMF_KIND_I4), intent(out) :: valueList()
integer(ESMF_KIND_I8), intent(out) :: valueList()
real (ESMF_KIND_R4), intent(out) :: valueList()
real (ESMF_KIND_R8), intent(out) :: valueList()
logical, intent(out) :: valueList()
character (len = *), intent(out) :: valueList()

Supported values for <defaultvalueList> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultvalueList()
The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
attpack A handle to the Attribute package
<valueList> The valueList of the named Attribute
[<defaultvalueList>] The default value list of the named Attribute
[itemCount] The number of items in a multi-valued Attribute
[isPresent] A logical flag to tell if this Attribute is present or not
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.12 ESMF_AttributeGet - Get an Attribute pointing to internal class information from an ESMF_AttPack

INTERFACE:

subroutine ESMF_AttributeGet(<object>, name, attpack, <valueList>, &
<defaultvalueList>, inputList, itemCount, isPresent, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
type(ESMF_AttPack), intent(inout) :: attpack
<valueList>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
<defaultvalueList>, see below for supported values
character (len = *), intent(in), optional :: inputList(:)
integer, intent(out), optional :: itemCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc
DESCRIPTION:

Return an Attribute valueList from the <object>, or from an Attribute package on the <object>, specified by attpack. Internal class information can be retrieved by prepending `ESMF:` to the name of the piece of information that is requested. See Section 38.5 for more information on this capability. A defaultvalueList list argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

```
  type(ESMF_Grid), intent(in) :: grid
```

Supported values for <valueList> are:

```
  integer(ESMF_KIND_I4), intent(out) :: valueList()
  real (ESMF_KIND_R8), intent(out) :: valueList()
  logical, intent(out) :: valueList()
```

Supported values for <defaultvalueList> are:

```
  integer(ESMF_KIND_I4), intent(in), optional :: defaultvalueList()
  real (ESMF_KIND_R8), intent(in), optional :: defaultvalueList()
  logical, intent(in), optional :: defaultvalueList()
```

The arguments are:

- `<object>` An ESMF object
- `<name>` The name of the Attribute to retrieve
- `<attpack>` A handle to the Attribute package
- `<valueList>` The valueList of the named Attribute
- `<defaultvalueList>` The default value list of the named Attribute
- `<inputList>` A list of the input parameters required to retrieve internal info
- `<ItemCount>` The number of items in a multi-valued Attribute
- `<isPresent>` A logical flag to tell if this Attribute is present or not
- `<rc>` Return code; equals ESMF_SUCCESS if there are no errors
38.11.13 ESMF_AttributeGet - Get an Attribute

INTERFACE:

    subroutine ESMF_AttributeGet(<object>, name, <value>, <defaultvalue>, &
    convention, purpose, attPackInstanceName, isPresent, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
<value>, see below for supported values
<defaultvalue>, see below for supported values
character (len = *), intent(in), optional :: convention
class (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute value from the <object>, or from an Attribute package on the <object>, specified by
convention, purpose, and attPackInstanceName. Internal information can also be retrieved from Grid
objects by prepending ‘ESMF:’ to the name of the piece of information that is requested. See Section [38.5] for more
information on which pieces of Grid data can be retrieved through this interface. A defaultvalue argument may
be given if a return code is not desired when the Attribute is not found. See Section [38.2] for a description of Attribute
packages.

Supported values for <object> are:

type(ESMF_Array), intent(in) :: array
type(ESMF_ArrayBundle), intent(in) :: arraybundle
type(ESMF_CplComp), intent(in) :: comp
type(ESMF_GridComp), intent(in) :: comp
type(ESMF_SciComp), intent(in) :: comp
type(ESMF_DistGrid), intent(in) :: distgrid
type(ESMF_Field), intent(in) :: field
type(ESMF_FieldBundle), intent(in) :: fieldbundle
type(ESMF_Grid), intent(in) :: grid
type(ESMF_State), intent(in) :: state

Supported values for <value> are:

integer(ESMF_KIND_I4), intent(out) :: value
integer(ESMF_KIND_I8), intent(out) :: value

867
real (ESMF_KIND_R4), intent(out) :: value
real (ESMF_KIND_R8), intent(out) :: value
logical, intent(out) :: value
character (len = *), intent(out) :: value

Supported values for <defaultvalue> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultvalue
integer(ESMF_KIND_I8), intent(in), optional :: defaultvalue
real (ESMF_KIND_R4), intent(in), optional :: defaultvalue
real (ESMF_KIND_R8), intent(in), optional :: defaultvalue
logical, intent(in), optional :: defaultvalue
character (len = *), intent(in), optional :: defaultvalue

The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
<value> The value of the named Attribute
[<defaultvalue>] The default value of the named Attribute
[convention] The convention of the Attribute package.
[purpose] The purpose of the Attribute package.
[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.
[isPresent] A logical flag to tell if this Attribute is present or not
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.14 ESMF_AttributeGet - Get an Attribute pointing to internal class information

INTERFACE:

    subroutine ESMF_AttributeGet(<object>, name, <value>, <defaultvalue>, &
inputList, convention, purpose, attPackInstanceName, isPresent, rc)

ARGUMENTS:
<object>, see below for supported values
character (len = *), intent(in) :: name
<value>, see below for supported values
<defaultvalue>, see below for supported values
character (len = *), intent(in), optional :: inputList(:)
character (len = *), intent(in), optional :: convention
character (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute value from the <object>, or from an Attribute package on the <object>, specified by convention, purpose, and attPackInstanceName. Internal class information can be retrieved by prepending 'ESMF:' to the name of the piece of information that is requested. See Section 38.5 for more information on this capability. A defaultvalue argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Grid), intent(in) :: grid

Supported values for <value> are:

integer(ESMF_KIND_I4), intent(out) :: value
character (len = *), intent(out) :: value

Supported values for <defaultvalue> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultvalue
character (len = *), intent(in), optional :: defaultvalue

The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
<value argument> The value of the named Attribute
[<defaultvalue argument>] The default value of the named Attribute
[inputList] A list of the input parameters required to retrieve internal info
[convention] The convention of the Attribute package.
[purpose] The purpose of the Attribute package.
[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.
[isPresent] A logical flag to tell if this Attribute is present or not
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.15 ESMF_AttributeGet - Get an Attribute

INTERFACE:

```
subroutine ESMF_AttributeGet(<object>, name, <valueList>, &
<defaultValueList>, convention, purpose, attPackInstanceName, &
itemCount, isPresent, rc)
```

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name

<valueList>, see below for supported values
<defaultValueList>, see below for supported values
character (len = *), intent(in), optional :: convention
character (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
integer, intent(out), optional :: itemCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute valueList from the <object>, or from an Attribute package on the <object>, specified by convention, purpose, and attPackInstanceName. Internal information can also be retrieved from Grid objects by prepending 'ESMF:' to the name of the piece of information that is requested. See Section 38.5 for more information on which pieces of Grid data can be retrieved through this interface. A defaultvalueList list argument may be given if a return code is not desired when the Attribute is not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

- type(ESMF_Array), intent(in) :: array
- type(ESMF_ArrayBundle), intent(in) :: arraybundle
- type(ESMF_CplComp), intent(in) :: comp
- type(ESMF_GridComp), intent(in) :: comp
- type(ESMF_SciComp), intent(in) :: comp
- type(ESMF_DistGrid), intent(in) :: distgrid
- type(ESMF_Field), intent(in) :: field
- type(ESMF_FieldBundle), intent(in) :: fieldbundle
- type(ESMF_Grid), intent(in) :: grid
- type(ESMF_State), intent(in) :: state

Supported values for <valueList> are:

integer(ESMF_KIND_I4), intent(out) :: valueList()
integer(ESMF_KIND_I8), intent(out) :: valueList(:)
real (ESMF_KIND_R4), intent(out) :: valueList(:)
real (ESMF_KIND_R8), intent(out) :: valueList(:)
logical, intent(out) :: valueList(:)
character (len = *), intent(out) :: valueList(:)

Supported values for <defaultvalueList> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultValueList(:)
integer(ESMF_KIND_I8), intent(in), optional :: defaultValueList(:)
real (ESMF_KIND_R4), intent(in), optional :: defaultValueList(:)
real (ESMF_KIND_R8), intent(in), optional :: defaultValueList(:)
logical, intent(in), optional :: defaultValueList(:)
character (len = *), intent(in), optional :: defaultValueList(:)

The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
<valueList> The valueList of the named Attribute
[<defaultvalueList>] The default value list of the named Attribute
[convention] The convention of the Attribute package.
[purpose] The purpose of the Attribute package.
[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.
[itemCount] The number of items in a multi-valued Attribute
[isPresent] A logical flag to tell if this Attribute is present or not
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.16 ESMF_AttributeGet - Get an Attribute pointing to internal class information

INTERFACE:

subroutine ESMF_AttributeGet(<object>, name, <valueList>, &
<defaultvalueList>, inputList, convention, purpose, attPackInstanceName, &
itemCount, isPresent, rc)
ARGUMENTS:

<object>, see below for supported values
component type (len = *), intent(in) :: name
<valueList>, see below for supported values
<defaultvalueList>, see below for supported values
component character (len = *), intent(in), optional :: inputList(:)
component character (len = *), intent(in), optional :: convention
component character (len = *), intent(in), optional :: purpose
component character (len = *), intent(in), optional :: attPackInstanceName
component integer, intent(out), optional :: itemCount
component logical, intent(out), optional :: isPresent
component integer, intent(out), optional :: rc

DESCRIPTION:

Return an Attribute valueList from the <object>, or from an Attribute package on the <object>, specified by
convention, purpose, and attPackInstanceName. Internal class information can be retrieved by prepending
"ESMF:" to the name of the piece of information that is requested. See Section 38.5 for more information on this
capability. A defaultvalueList list argument may be given if a return code is not desired when the Attribute is
not found. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Grid), intent(in) :: grid

Supported values for <valueList> are:

integer(ESMF_KIND_I4), intent(out) :: valueList(:)
real (ESMF_KIND_R8), intent(out) :: valueList(:)
logical, intent(out) :: valueList(:)

Supported values for <defaultvalueList> are:

integer(ESMF_KIND_I4), intent(in), optional :: defaultvalueList(:)
real (ESMF_KIND_R8), intent(in), optional :: defaultvalueList(:)
logical, intent(in), optional :: defaultvalueList(:)

The arguments are:

<object> An ESMF object
name The name of the Attribute to retrieve
<valueList> The valueList of the named Attribute
[<defaultvalueList>] The default value list of the named Attribute
[inputList] A list of the input parameters required to retrieve internal info
[convention] The convention of the Attribute package.
[purpose] The purpose of the Attribute package.

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.

[itemCount] The number of items in a multi-valued Attribute

[isPresent] A logical flag to tell if this Attribute is present or not

[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.17 ESMF_AttributeGet - Get the Attribute count

INTERFACE:

! Private name; call using ESMF_AttributeGet()
subroutine ESMF_AttributeGetCount(<object>, count, attcountflag, rc)

ARGUMENTS:

<object>, see below for supported values
integer, intent(out) :: count
type(ESMF_AttGetCountFlag), intent(in), optional :: attcountflag
integer, intent(out), optional :: rc

DESCRIPTION:

Return the Attribute count for <object>.

Supported values for <object> are:

type(ESMF_Array), intent(in) :: array
type(ESMF_ArrayBundle), intent(in) :: arraybundle
type(ESMF_CplComp), intent(in) :: comp
type(ESMF_GridComp), intent(in) :: comp
type(ESMF_SciComp), intent(in) :: comp
type(ESMF_DistGrid), intent(in) :: distgrid
type(ESMF_Field), intent(in) :: field
type(ESMF_FieldBundle), intent(in) :: fieldbundle
type(ESMF_Grid), intent(in) :: grid
type(ESMF_State), intent(in) :: state

The arguments are:
**<object>** An ESMF object

count  The Attribute count for <object>

[attcountflag]  The flag to specify which attribute count to return, the default is ESMF_ATTGETCOUNT_ATTRIBUTE. This flag is documented in section 38.6.1.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors

---

**38.11.18 ESMF_AttributeGet - Get Attribute info by name from an ESMF_AttPack**

**INTERFACE:**

```fortran
! Private name; call using ESMF_AttributeGet()
subroutine ESMF_AttributeGetInfoByNameAP(<object>, name, attpack, &
typekind, itemCount, isPresent, rc)
```

**ARGUMENTS:**

- `<object>`, see below for supported values
- character (len = *), intent(in) :: name
- type(ESMF_AttPack), intent(inout) :: attpack

**DESCRIPTION:**

Return information associated with an Attribute in an Attribute package, including typekind and itemCount.

Supported values for `<object>` are:

- type(ESMF_Array), intent(in) :: array
- type(ESMF_ArrayBundle), intent(in) :: arraybundle
- type(ESMF_CplComp), intent(in) :: comp
- type(ESMF_GridComp), intent(in) :: comp
- type(ESMF_SciComp), intent(in) :: comp
- type(ESMF_DistGrid), intent(in) :: distgrid
- type(ESMF_Field), intent(in) :: field
- type(ESMF_FieldBundle), intent(in) :: fieldbundle
- type(ESMF_Grid), intent(in) :: grid
- type(ESMF_State), intent(in) :: state
The arguments are:

<object>  An ESMF object
name  The name of the Attribute to query
attpack  A handle to the Attribute package
[typekind]  The typekind of the Attribute
[itemCount]  The number of items in this Attribute
[isPresent]  A logical flag to tell if this Attribute is present or not
[rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.19  ESMF_AttributeGet - Get Attribute info by name

INTERFACE:

! Private name; call using ESMF_AttributeGet()
subroutine ESMF_AttributeGetInfoByNam(<object>, name, &
  convention, purpose, attPackInstanceName, &
  typekind, itemCount, isPresent, rc)

ARGUMENTS:

<object>, see below for supported values
class (len = *), intent(in) :: name
--  The following arguments require argument keyword syntax (e.g. rc=rc). --
class (len=*), intent(in), optional :: convention
class (len=*), intent(in), optional :: purpose
class (len=*), intent(in), optional :: attPackInstanceName
type(ESMF_TypeKind_Flag), intent(out), optional :: typekind
integer, intent(out), optional :: itemCount
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Return information associated with the named Attribute, including typekind and itemCount. Supported values for <object> are:

type(ESMF_Array), intent(in) :: array
type(ESMF_ArrayBundle), intent(in) :: arraybundle
type(ESMF_CplComp), intent(in) :: comp
type(ESMF_GridComp), intent(in) :: comp
The arguments are:

<object> An ESMF object

name The name of the Attribute to query

[convention] The convention of the Attribute package.

[purpose] The purpose of the Attribute package.

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance. (Not implemented yet)

[typekind] The typekind of the Attribute

[itemCount] The number of items in this Attribute

[isPresent] A logical flag to tell if this Attribute is present or not

[rc] Return code; equals ESMF_SUCCESS if there are no errors
DESCRIPTION:

Returns information associated with the indexed Attribute, including name, typekind and itemCount. Keep in mind that these indexes start from 1, as expected in a Fortran API.

Supported values for <object> are:

- type(ESMF_Array), intent(in) :: array
- type(ESMF_ArrayBundle), intent(in) :: arraybundle
- type(ESMF_CplComp), intent(in) :: comp
- type(ESMF_GridComp), intent(in) :: comp
- type(ESMF_SciComp), intent(in) :: comp
- type(ESMF_DistGrid), intent(in) :: distgrid
- type(ESMF_Field), intent(in) :: field
- type(ESMF_FieldBundle), intent(in) :: fieldbundle
- type(ESMF_Grid), intent(in) :: grid
- type(ESMF_State), intent(in) :: state

The arguments are:

<object> An ESMF object
attributeIndex The index number of the Attribute to query
name The name of the Attribute
[typekind] The typekind of the Attribute
[itemCount] The number of items in this Attribute
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.21  ESMF_AttributeGet - Get Attribute package instance names from an ESMF_AttPack

INTERFACE:

! Private name; call using ESMF_AttributeGet()
subroutine ESMF_AttributeGetAPinstNamesAP(<object>, attpack, &
attPackInstanceNameList, attPackInstanceNameCount, rc)

ARGUMENTS:
Get the Attribute package instance names of the ESMF_AttPack. Also get the number of such names. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

- type(ESMF_CplComp), intent(in) :: comp
- type(ESMF_GridComp), intent(in) :: comp
- type(ESMF_SciComp), intent(in) :: comp

The arguments are:

<object> An ESMF object
attpack A handle to the Attribute package
attPackInstanceNameList The name(s) of the Attribute package instances of the given convention and purpose.
attpackInstanceNameCount The number of Attribute package instance names.
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.22 ESMF_AttributeGet - Get Attribute package instance names

INTERFACE:

! Private name; call using ESMF_AttributeGet()
subroutine ESMF_AttributeGetAPInstNames(<object>, convention, purpose, &
attPackInstanceNameList, attPackInstanceNameCount, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in), :: convention
character (len = *), intent(in), :: purpose
character (len = *), intent(out) :: attPackInstanceNameList(:)
integer, intent(out) :: attPackInstanceNameCount
integer, intent(out), optional :: rc

878
DESCRIPTION:

Get the Attribute package instance names of the specified convention and purpose. Also get the number of such names. See Section 38.2 for a description of Attribute packages and their conventions, purposes, and object types.

Supported values for <object> are:

- type(ESMF_CplComp), intent(in) :: comp
- type(ESMF_GridComp), intent(in) :: comp
- type(ESMF_SciComp), intent(in) :: comp

The arguments are:

- <object> An ESMF object
- convention The convention of the Attribute package instances.
- purpose The purpose of the Attribute package instances.
- attPackInstanceNameList The name(s) of the Attribute package instances of the given convention and purpose.
- attPackInstanceNameCount The number of Attribute package instance names.
- [rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.23 ESMF_AttributeGetAttPack - Get an ESMF Attribute package object using a specification list

INTERFACE:

! Private name; call using ESMF_AttributeGetAttPack()
subroutine ESMF_AttGetAttPackSL(<object>, specList, keywordEnforcer, attpack, isPresent, rc)

ARGUMENTS:

- <object>, see below for supported values
  character (len = *), intent(in) :: specList(:)
- -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_AttPack), intent(inout), optional :: attpack
  logical, intent(out), optional :: isPresent
  integer, intent(out), optional :: rc

DESCRIPTION:

Get an ESMF Attribute package object. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

- type(ESMF_Array), intent(inout) :: array
The arguments are:

<object> An ESMF object

specList A character list of values which identify the Attribute package, such as convention, purpose, and instance-name.

[attpack] A handle to the Attribute package

[isPresent] A logical flag to tell if this Attribute package is present or not

[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.24 ESMF_AttributeGetAttPack - Get an ESMF Attribute package object

INTERFACE:

! Private name; call using ESMF_AttributeGetAttPack()
subroutine ESMF_AttributeGetAttPack(<object>, convention, purpose, keywordEnforcer
attPackInstanceName, attpack, isPresent, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: convention
character (len = *), intent(in) :: purpose
-- The following arguments require argument keyword syntax (e.g. rc=rc).
-- character (len = *), intent(in), optional :: attPackInstanceName
type(ESMF_AttPack), intent(inout), optional :: attpack
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

DESCRIPTION:

Get an ESMF Attribute package object. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:
The arguments are:

<object> An ESMF object

convention The convention of the Attribute package

purpose The purpose of the Attribute package

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.

[attpack] A handle to the Attribute package

[isPresent] A logical flag to tell if this Attribute package is present or not

[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.25 ESMF_AttributeLink - Link a Component Attribute hierarchy to that of a Component or State

INTERFACE:

! Private name; call using ESMF_AttributeLink()
subroutine ESMF_CompAttLink(<object1>, <object2>, rc)

ARGUMENTS:

<object1>, see below for supported values
<object2>, see below for supported values
integer, intent(out), optional :: rc
DESCRIPTION:

Attach a CplComp, GridComp, or SciComp Attribute hierarchy to the hierarchy of a CplComp, GridComp, SciComp, or State.

Supported values for the <object1> are:

- type(ESMF_CplComp), intent(inout) :: comp1
- type(ESMF_GridComp), intent(inout) :: comp1
- type(ESMF_SciComp), intent(inout) :: comp1

Supported values for the <object2> are:

- type(ESMF_CplComp), intent(in) :: comp2
- type(ESMF_GridComp), intent(in) :: comp2
- type(ESMF_SciComp), intent(in) :: comp2
- type(ESMF_State), intent(in) :: state

The arguments are:

<object1> The “parent” object in the Attribute hierarchy link  
<object2> The “child” object in the Attribute hierarchy link  
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.26 ESMF_AttributeLink - Link a State Attribute hierarchy with the hierarchy of an Array, ArrayBundle, Field, FieldBundle, or State

INTERFACE:

! Private name; call using ESMF_AttributeLink()  
subroutine ESMF_StateAttLink(state, <object>, rc)

ARGUMENTS:

- type(ESMF_State), intent(inout) :: state
- <object>, see below for supported values
- integer, intent(out), optional :: rc

DESCRIPTION:

Attach a State Attribute hierarchy to the hierarchy of a Fieldbundle, Field, or another State. 

Supported values for the <object> are:
The arguments are:

state  An ESMF_State object
<object> The object with which to link hierarchies
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.27 ESMF_AttributeLink - Link a FieldBundle and Field Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeLink()
subroutine ESMF_FieldBundleAttLink(fieldbundle, field, rc)

ARGUMENTS:

type(ESMF_FieldBundle), intent(inout) :: fieldbundle
type(ESMF_Field), intent(in) :: field
integer, intent(out), optional :: rc

DESCRIPTION:

Attach a FieldBundle Attribute hierarchy to the hierarchy of a Field.

The arguments are:

fieldbundle An ESMF_FieldBundle object
field An ESMF_Field object
[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.28  ESMF_AttributeLink - Link a Field and Grid Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeLink()
subroutine ESMF_FieldAttLink(field, grid, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_Grid), intent(in) :: grid
integer, intent(out), optional :: rc

DESCRIPTION:

Attach a Field Attribute hierarchy to the hierarchy of a Grid.
The arguments are:

field  An ESMF_Field object
grid   An ESMF_Grid object
[rc]   Return code; equals ESMF_SUCCESS if there are no errors

38.11.29  ESMF_AttributeLink - Link an ArrayBundle and Array Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeLink()
subroutine ESMF_ArrayBundleAttLink(arraybundle, array, rc)

ARGUMENTS:

  type(ESMF_ArrayBundle), intent(inout) :: arraybundle
  type(ESMF_Array), intent(in) :: array
  integer, intent(out), optional :: rc

DESCRIPTION:

Attach an ArrayBundle Attribute hierarchy to the hierarchy of an Array.
The arguments are:

arraybundle  An ESMF_ArrayBundle object
array    An ESMF_Array object
[rc]   Return code; equals ESMF_SUCCESS if there are no errors
38.11.30  ESMF_AttributeLinkRemove - Unlink a Component Attribute hierarchy from that of a Component or State

INTERFACE:

! Private name; call using ESMF_AttributeLinkRemove()
subroutine ESMF_CompAttLinkRemove(<object1>, <object2>, rc)

ARGUMENTS:

<object1>, see below for supported values
<object2>, see below for supported values
integer, intent(out), optional :: rc

DESCRIPTION:

Unattach a CplComp, GridComp, or SciComp Attribute hierarchy from the hierarchy of a CplComp, GridComp, SciComp, or State.

Supported values for the <object1> are:

  type(ESMF_CplComp), intent(inout) :: comp1
  type(ESMF_GridComp), intent(inout) :: comp1
  type(ESMF_SciComp), intent(inout) :: comp1

Supported values for the <object2> are:

  type(ESMF_CplComp), intent(in) :: comp2
  type(ESMF_GridComp), intent(in) :: comp2
  type(ESMF_SciComp), intent(in) :: comp2
  type(ESMF_State), intent(in) :: state

The arguments are:

<object1>  The “parent” object in the Attribute hierarchy link
<object2>  The “child” object in the Attribute hierarchy link
[rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.31  ESMF_AttributeLinkRemove - Unlink a State Attribute hierarchy from the hierarchy of an Array, ArrayBundle, Field, FieldBundle, or State

INTERFACE:
subroutine ESMF_StateAttLinkRemove(state, <object>, rc)

ARGUMENTS:

  type(ESMF_State), intent(inout) :: state
  <object>, see below for supported values
  integer, intent(out), optional :: rc

DESCRIPTION:

Unattach a State Attribute hierarchy from the hierarchy of a Fieldbundle, Field, or another State.
Supported values for the <object> are:

  type(ESMF_Array), intent(in) :: array
  type(ESMF_ArrayBundle), intent(in) :: arraybundle
  type(ESMF_Field), intent(in) :: field
  type(ESMF_FieldBundle), intent(in) :: fieldbundle
  type(ESMF_State), intent(in) :: state

The arguments are:

  state  An ESMF_State object
  <object>  The object with which to unlink hierarchies
  [rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.32  ESMF_AttributeLinkRemove - Unlink a FieldBundle and Field Attribute hierarchy

INTERFACE:

subroutine ESMF_FieldBundleAttLinkRemove(fieldbundle, field, rc)

ARGUMENTS:

  type(ESMF_FieldBundle), intent(inout) :: fieldbundle
  type(ESMF_Field), intent(in) :: field
  integer, intent(out), optional :: rc

DESCRIPTION:

Unattach a FieldBundle Attribute hierarchy from the hierarchy of a Field.

The arguments are:
fieldbundle An ESMF_FieldBundle object
field An ESMF_Field object
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.33 ESMF_AttributeLinkRemove - Unlink a Field and Grid Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeLinkRemove()
subroutine ESMF_FieldAttLinkRemove(field, grid, rc)

ARGUMENTS:

type(ESMF_Field), intent(inout) :: field
type(ESMF_Grid), intent(in) :: grid
integer, intent(out), optional :: rc

DESCRIPTION:

Unattach a Field Attribute hierarchy from the hierarchy of a Grid.

The arguments are:

field An ESMF_Field object
grid An ESMF_Grid object
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.34 ESMF_AttributeLinkRemove - Unlink an ArrayBundle and Array Attribute hierarchy

INTERFACE:

! Private name; call using ESMF_AttributeLinkRemove()
subroutine ESMF_ArrayBundleAttLinkRemove(arraybundle, array, rc)

ARGUMENTS:

type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_Array), intent(in) :: array
integer, intent(out), optional :: rc
DESCRIPTION:

Unattach an ArrayBundle Attribute hierarchy from the hierarchy of an Array.

The arguments are:

arraybundle  An ESMF_ArrayBundle object

array  An ESMF_Array object

[rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.35  ESMF_AttributeRead - Read Attributes from an XML file

INTERFACE:

    subroutine ESMF_AttributeRead(<object>, fileName, schemaFileName, rc)

ARGUMENTS:

    <object>, see below for supported values
    character (len = *), intent(in), optional :: fileName
    character (len = *), intent(in), optional :: schemaFileName
    integer, intent(out), optional :: rc

DESCRIPTION:

Read Attributes for <object> from fileName, whose format is XML. schemaFileName format is XSD. If present, the
schemaFileName is used to validate the contents of fileName. schemaFileName must be specified for a fileName
containing custom, user-defined Attributes.

Requires the third party Xerces C++ XML Parser library to be installed, v3.1.0 or better. For more details, see the
"ESMF Users Guide", "Building and Installing the ESMF, Third Party Libraries, Xerces" and the website
"http://xerces.apache.org/xerces-c". Also please see the section on Attribute I/O.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array ! not yet implemented

type(ESMF_ArrayBundle), intent(inout) :: arrayBundle ! not yet implemented

type(ESMF_CplComp), intent(inout) :: cplComp

type(ESMF_GridComp), intent(inout) :: gridComp

type(ESMF_SciComp), intent(inout) :: gridComp

type(ESMF_Field), intent(inout) :: field

type(ESMF_FieldBundle), intent(inout) :: fieldbundle ! not yet implemented

type(ESMF_Grid), intent(inout) :: grid
The arguments are:

<object>  The ESMF object onto which the read Attributes will be placed
[fileName]  The name of the XML file to read
[schemaFileName]  The name of the XSD file to validate the contents of fileName
[rc]  Return code; equals ESMF_SUCCESS if there are no errors

38.11.36  ESMF_AttributeRemove - Remove an Attribute or Attribute package using an ESMF_AttPack

INTERFACE:

subroutine ESMF_AttributeRemove(<object>, name, &
   attpack, rc)

ARGUMENTS:

<object>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character (len = *), intent(in), optional :: name
type(ESMF_AttPack), intent(inout) :: attpack
integer, intent(out), optional :: rc

DESCRIPTION:

Remove an Attribute, or Attribute package on <object>. See Section[38.2 for a description of Attribute packages and their conventions, purposes, and object types.

Supported values for <object> are:

   type(ESMF_Array), intent(inout) :: array
   type(ESMF_ArrayBundle), intent(inout) :: arraybundle
   type(ESMF_CplComp), intent(inout) :: comp
   type(ESMF_GridComp), intent(inout) :: comp
   type(ESMF_SciComp), intent(inout) :: comp
   type(ESMF_DistGrid), intent(inout) :: distgrid
   type(ESMF_Field), intent(inout) :: field
   type(ESMF_FieldBundle), intent(inout) :: fieldbundle
   type(ESMF_Grid), intent(inout) :: grid
type(ESMF_State), intent(inout) :: state

The arguments are:

<object> An ESMF object

[name] The name of the Attribute to remove

attpack A handle to the Attribute package

[rc] Return code; equals ESMF_SUCCESS if there are no errors

NOTE: An entire Attribute package can be removed by specifying attpack only, without name. By specifying attpack an Attribute will be removed from the corresponding Attribute package, if it exists. An Attribute can be removed directly from <object> by specifying name, without attpack.

38.11.37 ESMF_AttributeRemove - Remove an Attribute or Attribute package

INTERFACE:

subroutine ESMF_AttributeRemove(<object>, name, convention, purpose, &
attPackInstanceName, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in), optional :: name
character (len = *), intent(in), optional :: convention
character (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
integer, intent(out), optional :: rc

DESCRIPTION:

Remove an Attribute, or Attribute package on <object>. See Section 38.2 for a description of Attribute packages and their conventions, purposes, and object types.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_DistGrid), intent(inout) :: distgrid
type(ESMF_Field), intent(inout) :: field
type(ESMF_FieldBundle), intent(inout) :: fieldbundle

The arguments are:

<object> An ESMF object

[name] The name of the Attribute to remove

[convention] The convention of the Attribute package.

[purpose] The purpose of the Attribute package.

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance.

[rc] Return code; equals ESMF_SUCCESS if there are no errors

NOTE: An entire Attribute package can be removed by specifying convention, purpose, and attPackInstanceName only, without name. An Attribute can be removed directly from <object> by specifying name, without convention, purpose, and attPackInstanceName.

38.11.38 ESMF_AttributeSet - Set an Attribute in an ESMF_AttPack

INTERFACE:

subroutine ESMF_AttributeSet(<object>, name, <value>, attpack, & rc)

ARGUMENTS:

<object>, see below for supported values
classer (len = *), intent(in) :: name
<value>, see below for supported values
type(ESMF_AttPack), intent(inout) :: attpack
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and value, and, if in an Attribute package, a attpack. See Section 38.11 for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array

type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_DistGrid), intent(inout) :: distgrid
type(ESMF_Field), intent(inout) :: field
type(ESMF_FieldBundle), intent(inout) :: fieldbundle
type(ESMF_Grid), intent(inout) :: grid
type(ESMF_State), intent(inout) :: state

Supported values for the <value> are:

integer(ESMF_KIND_I4), intent(in) :: value
integer(ESMF_KIND_I8), intent(in) :: value
real (ESMF_KIND_R4), intent(in) :: value
real (ESMF_KIND_R8), intent(in) :: value
logical, intent(in) :: value
character (len = *), intent(in) :: value

The arguments are:

<object> An ESMF object
name The name of the Attribute to set
<value argument> The value of the Attribute to set
attpack A handle to the Attribute package
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.39 ESMF_AttributeSet - Set an Attribute to point to internal class information in an ESMF_AttPack

INTERFACE:

    subroutine ESMF_AttributeSet(<object>, name, <value>, attpack, &
    inputList, rc)

ARGUMENTS:
<object>, see below for supported values
character (len = *), intent(in) :: name
$value$, see below for supported values
type(ESMF_AttPack), intent(inout) :: attpack

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character (len = *), intent(in), optional :: inputList(:)
integer, intent(out), optional :: rc

DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and value, and, if in an Attribute package, an attpack. See Section 38.2 for a description of Attribute packages. The Attribute can also be set to be a pointer to internal class information. See Section 38.5 for a description of this capability.

Supported values for <object> are:

type(ESMF_Grid), intent(inout) :: grid

Supported values for the <value> are:

character (len = *), intent(in), :: value

The arguments are:

<object> An ESMF object
name The name of the Attribute to set
$value$ argument The value of the Attribute to set
attpack A handle to the Attribute package
$inputList$ A list of the input parameters required to set internal info
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.40 ESMF_AttributeSet - Set an Attribute in an ESMF_AttPack

INTERFACE:

subroutine ESMF_AttributeSet(<object>, name, <valueList>, attpack, & itemCount, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
$valueList$, see below for supported values
type(ESMF_AttPack), intent(in) :: attpack

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: itemCount
integer, intent(out), optional :: rc
DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and a valueList, with an itemCount, and, if in an Attribute package, an attpack. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

- `type(ESMF_Array), intent(inout) :: array`
- `type(ESMF_ArrayBundle), intent(inout) :: arraybundle`
- `type(ESMF_CplComp), intent(inout) :: comp`
- `type(ESMF_GridComp), intent(inout) :: comp`
- `type(ESMF_SciComp), intent(inout) :: comp`
- `type(ESMF_DistGrid), intent(inout) :: distgrid`
- `type(ESMF_Field), intent(inout) :: field`
- `type(ESMF_FieldBundle), intent(inout) :: fieldbundle`
- `type(ESMF_Grid), intent(inout) :: grid`
- `type(ESMF_State), intent(inout) :: state`

Supported values for the <valueList> are:

- `integer(ESMF_KIND_I4), intent(in) :: valueList(:)`
- `integer(ESMF_KIND_I8), intent(in) :: valueList(:)`
- `real (ESMF_KIND_R4), intent(in) :: valueList(:)`
- `real (ESMF_KIND_R8), intent(in) :: valueList(:)`
- `logical, intent(in) :: valueList(:)`
- `character (len = *), intent(in) :: valueList(:)`

The arguments are:

- `<object>` An ESMF object
- `name` The name of the Attribute to set
- `<valueList argument>` The valueList of the Attribute to set
- `attpack` A handle to the Attribute package
- `[itemCount]` The number of items in a multi-valued Attribute
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors

EOP!—

894
38.11.41 ESMF_AttributeSet - Set an Attribute

INTERFACE:

    subroutine ESMF_AttributeSet(<object>, name, <value>, &
    convention, purpose, attPackInstanceName, rc)

ARGUMENTS:

    <object>, see below for supported values
character (len = *), intent(in) :: name
    <value>, see below for supported values
character (len = *), intent(in), optional :: convention
character (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
integer, intent(out), optional :: rc

DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and value, and, if in an Attribute package, convention, purpose, and attPackInstanceName. See Section 38.2 for a description of Attribute packages.

Supported values for <object> are:

    type(ESMF_Array), intent(inout) :: array
    type(ESMF_ArrayBundle), intent(inout) :: arraybundle
    type(ESMF_CplComp), intent(inout) :: comp
    type(ESMF_GridComp), intent(inout) :: comp
    type(ESMF_SciComp), intent(inout) :: comp
    type(ESMF_DistGrid), intent(inout) :: distgrid
    type(ESMF_Field), intent(inout) :: field
    type(ESMF_FieldBundle), intent(inout) :: fieldbundle
    type(ESMF_Grid), intent(inout) :: grid
    type(ESMF_State), intent(inout) :: state

Supported values for the <value> are:

    integer(ESMF_KIND_I4), intent(in) :: value
    integer(ESMF_KIND_I8), intent(in) :: value
    real (ESMF_KIND_R4), intent(in) :: value
    real (ESMF_KIND_R8), intent(in) :: value
    logical, intent(in) :: value
character (len = *), intent(in) :: value

The arguments are:

<object>   An ESMF object
name The name of the Attribute to set
<value argument> The value of the Attribute to set
[convention] The convention of the Attribute package.
[purpose] The purpose of the Attribute package.
[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance. (Not implemented yet)
[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.42  ESMF_AttributeSet - Set an Attribute to point to internal class information

INTERFACE:

subroutine ESMF_AttributeSet(<object>, name, <value>, inputList, convention, purpose, attPackInstanceName, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
<value>, see below for supported values
character (len = *), intent(in), optional :: inputList(:)
character (len = *), intent(in), optional :: convention
class (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
integer, intent(out), optional :: rc

DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and value, and, if in an Attribute package, convention, purpose, and attPackInstanceName. See Section 38.2 for a description of Attribute packages. The Attribute can also be set to be a pointer to internal class information. See Section 38.3 for a description of this capability.

Supported values for <object> are:

type(ESMF_Grid), intent(inout) :: grid

Supported values for the <value> are:
The arguments are:

<object> An ESMF object

name The name of the Attribute to set

<value argument> The value of the Attribute to set

[inputList] A list of the input parameters required to set internal info

[convention] The convention of the Attribute package.

[purpose] The purpose of the Attribute package.

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance. (Not implemented yet)

[rc] Return code; equals ESMF_SUCCESS if there are no errors

38.11.43 ESMF_AttributeSet - Set an Attribute

INTERFACE:

subroutine ESMF_AttributeSet(<object>, name, <valueList>, &
   convention, purpose, attPackInstanceName, itemCount, rc)

ARGUMENTS:

<object>, see below for supported values
character (len = *), intent(in) :: name
<valueList>, see below for supported values
character (len = *), intent(in), optional :: convention
character (len = *), intent(in), optional :: purpose
character (len = *), intent(in), optional :: attPackInstanceName
integer, intent(in), optional :: itemCount
integer, intent(out), optional :: rc

DESCRIPTION:

Attach an Attribute to <object>, or set an Attribute in an Attribute package. The Attribute has a name and a valueList, with an itemCount, and, if in an Attribute package, convention, purpose, and attPackInstanceName. See Section [38.2] for a description of Attribute packages.

Supported values for <object> are:

type(ESMF_Array), intent(inout) :: array
type(ESMF_ArrayBundle), intent(inout) :: arraybundle
type(ESMF_CplComp), intent(inout) :: comp
type(ESMF_GridComp), intent(inout) :: comp
type(ESMF_SciComp), intent(inout) :: comp
type(ESMF_DistGrid), intent(inout) :: distgrid

type(ESMF_Field), intent(inout) :: field
type(ESMF_FieldBundle), intent(inout) :: fieldbundle
type(ESMF_Grid), intent(inout) :: grid
type(ESMF_State), intent(inout) :: state

Supported values for the `<valueList>` are:

integer(ESMF_KIND_I4), intent(in) :: valueList(:)
integer(ESMF_KIND_I8), intent(in) :: valueList(:)
real (ESMF_KIND_R4), intent(in) :: valueList(:)
real (ESMF_KIND_R8), intent(in) :: valueList(:)
logical, intent(in) :: valueList(:)
character (len = *), intent(in) :: valueList(:)

The arguments are:

`<object>` An ESMF object

`name` The name of the Attribute to set

`<valueList argument>` The valueList of the Attribute to set

[convention] The convention of the Attribute package.

[purpose] The purpose of the Attribute package.

[attPackInstanceName] The name of an Attribute package instance, specifying which one of multiple Attribute package instances of the same convention and purpose, within a nest. If not specified, defaults to the first instance. (Not implemented yet)

[itemCount] The number of items in a multi-valued Attribute

[rc] Return code; equals ESMF_SUCCESS if there are no errors
38.11.44 ESMF_AttributeUpdate - Update an Attribute hierarchy

INTERFACE:

    subroutine ESMF_AttributeUpdate(<object>, vm, rootList, rc)

ARGUMENTS:

    <object>, see below for supported values
    type(ESMF_VM), intent(in) :: vm
    integer, intent(in) :: rootList(:)
    integer, intent(out), optional :: rc

DESCRIPTION:

Update an Attribute hierarchy during runtime. This call will not work if changes have been made to the underlying object hierarchy and ESMF_StateReconcile() has not already been called. There is a check that will fail if this case is encountered. The information from the PETs in the 'rootList' is transferred to the PETs that are not in the 'rootList'. Care should be taken to ensure that the information contained in the Attributes on the PETs in the 'rootList' is consistent.

Supported values for <object> are:

    type(ESMF_Array), intent(inout) :: array
    type(ESMF_ArrayBundle), intent(inout) :: arraybundle
    type(ESMF_CplComp), intent(inout) :: comp
    type(ESMF_GridComp), intent(inout) :: comp
    type(ESMF_SciComp), intent(inout) :: comp
    type(ESMF_Field), intent(inout) :: field
    type(ESMF_FieldBundle), intent(inout) :: fieldbundle
    type(ESMF_State), intent(inout) :: state

The arguments are:

    <object>  An ESMF object
    vm        The virtual machine over which this Attribute hierarchy should be updated
    rootList  The list of “root” PETs that are to be used to update
    [rc]      Return code; equals ESMF_SUCCESS if there are no errors
38.11.45 ESMF_AttributeWrite - Write an Attribute package

INTERFACE:

    subroutine ESMF_AttributeWrite(<object>, convention, purpose, &
    attwriteflag, rc)

ARGUMENTS:

    <object>, see below for supported values
    character (len = *), intent(in), optional :: convention
    character (len = *), intent(in), optional :: purpose
    type(ESMF_AttWriteFlag), intent(in), optional :: attwriteflag
    integer, intent(out), optional :: rc

DESCRIPTION:

Write the Attribute package for <object>. The Attribute package defines the convention, purpose, and object type of the associated Attributes. Either tab-delimited or xml format is achieved by using attwriteflag. Currently, only ESMF/ESG/CF Field Attribute packages can be written in tab-delimited format. See Section 38.2 for a description of Attribute packages and their conventions, purposes, and object types.

This call is collective across the current VM.

Writing Attribute XML files is performed with the standard C++ output file stream facility.

Note: For an object type of ESMF_GridComp, convention='WaterML', purpose='TimeSeries', and attwriteflag=ESMF_ATTRWRITE_XML, an XML file conforming to a hydrologic standard called WaterML will be written. See the following for more information:

"http://his.cuahsi.org/wofws.html"
"http://www.earthsystemcurator.org/projects/waterml.shtml"

An ESMF Use Test Case is available which showcases an example of how to write a WaterML file; please see

"http://esmf.cvs.sourceforge.net/viewvc/esmf/use_test_cases/ESMF_WaterML"
"http://esmf.cvs.sourceforge.net/viewvc/esmf/use_test_cases/README"

Supported values for <object> are:

type(ESMF_Array), intent(in) :: array

type(ESMF_ArrayBundle), intent(in) :: arraybundle

type(ESMF_CplComp), intent(in) :: comp

type(ESMF_GridComp), intent(in) :: comp

type(ESMF_SciComp), intent(in) :: comp

900
The arguments are:

<object> An ESMF object

[convention] The convention of the Attribute package

[purpose] The purpose of the Attribute package

[attwriteflag] The flag to specify which format is desired for the write, the default is ESMF_ATTWRITE_TAB. This flag is documented in section 38.6.3.

[rc] Return code; equals ESMF_SUCCESS if there are no errors

39 Time Manager Utility

The ESMF Time Manager utility includes software for time and date representation and calculations, model time advancement, and the identification of unique and periodic events. Since multi-component geophysical applications often require synchronization across the time management schemes of the individual components, the Time Manager’s standard calendars and consistent time representation promote component interoperability.

Key Features
Drift-free timekeeping through an integer-based internal time representation. Both integers and reals can be specified at the interface.
The ability to represent time as a rational fraction, to support exact timekeeping in applications that involve grid refinement.
Support for many calendar kinds, including user-customized calendars.
Support for both concurrent and sequential modes of component execution.
Support for varying and negative time steps.

39.1 Time Manager Classes

There are five ESMF classes that represent time concepts:

- **Calendar** A Calendar can be used to keep track of the date as an ESMF Gridded Component advances in time. Standard calendars (such as Gregorian and 360-day) and user-specified calendars are supported. Calendars can be queried for quantities such as seconds per day, days per month, and days per year.

- **Time** A Time represents a time instant in a particular calendar, such as November 28, 1964, at 7:31pm EST in the Gregorian calendar. The Time class can be used to represent the start and stop time of a time integration.

- **TimeInterval** TimeIntervals represent a period of time, such as 300 milliseconds. Time steps can be represented using TimeIntervals.

- **Clock** Clocks collect the parameters and methods used for model time advancement into a convenient package. A Clock can be queried for quantities such as start time, stop time, current time, and time step. Clock methods include incrementing the current time, and determining if it is time to stop.
- **Alarm** Alarms identify unique or periodic events by “ringing” - returning a true value - at specified times. For example, an Alarm might be set to ring on the day of the year when leaves start falling from the trees in a climate model.

The ESMF Time Manager utility includes software to manage model calendars, advance model time, and perform time and date calculations. The software classes that handle these functions are **Times**, **TimeIntervals**, **Clocks**, **Alarms**, and **Calendars**.
In the remainder of this section, we briefly summarize the functionality that the Time Manager classes provide. Detailed descriptions and usage examples precede the API listing for each class.

### 39.2 Calendar

An ESMF Calendar can be queried for seconds per day, days per month and days per year. The flexible definition of Calendars allows them to be defined for planetary bodies other than Earth. The set of supported calendars includes:

- **Gregorian** The standard Gregorian calendar.
- **no-leap** The Gregorian calendar with no leap years.
- **Julian** The standard Julian date calendar.
- **Julian Day** The standard Julian days calendar.
- **Modified Julian Day** The Modified Julian days calendar.
- **360-day** A 30-day-per-month, 12-month-per-year calendar.
- **no calendar** Tracks only elapsed model time in hours, minutes, seconds.

See Section 40.1 for more details on supported standard calendars, and how to create a customized ESMF Calendar.

### 39.3 Time Instants and TimeIntervals

TimeIntervals and Time instants (simply called Times) are the computational building blocks of the Time Manager utility. TimeIntervals support operations such as add, subtract, compare size, reset value, copy value, and subdivide by a scalar. Times, which are moments in time associated with specific Calendars, can be incremented or decremented by TimeIntervals, compared to determine which of two Times is later, differenced to obtain the TimeInterval between two Times, copied, reset, and manipulated in other useful ways. Times support a host of different queries, both for values of individual Time components such as year, month, day, and second, and for derived values such as day of year, middle of current month and Julian day. It is also possible to retrieve the value of the hardware realtime clock in the form of a Time. See Sections 41.1 and 42.1 respectively, for use and examples of Times and TimeIntervals.

Since climate modeling, numerical weather prediction and other Earth and space applications have widely varying time scales and require different sorts of calendars, Times and TimeIntervals must support a wide range of time specifiers, spanning nanoseconds to years. The interfaces to these time classes are defined so that the user can specify a time using a combination of units selected from the list shown in Table 39.4.

### 39.4 Clocks and Alarms

Although it is possible to repeatedly step a Time forward by a TimeInterval using arithmetic on these basic types, it is useful to identify a higher-level concept to represent this function. We refer to this capability as a Clock, and include in its required features the ability to store the start and stop times of a model run, to check when time advancement should cease, and to query the value of quantities such as the current time and the time at the previous time step. The Time Manager includes a class with methods that return a true value when a periodic or unique event has taken place; we refer to these as Alarms. Applications may contain temporary or multiple Clocks and Alarms. Sections 43.1 and 44.1 describe the use of Clocks and Alarms in detail.

39.5 Design and Implementation Notes

1. **Base TimeIntervals and Times on the same integer representation.** It is useful to allow both TimeIntervals and Times to inherit from a single class, BaseTime. In C++, this can be implemented by using inheritance. In Fortran, it can be implemented by having the derived types TimeIntervals and Times contain a derived type BaseTime. In both cases, the BaseTime class can be made private and invisible to the user.

   The result of this strategy is that Time Intervals and Times gain a consistent core representation of time as well a set of basic methods.

   The BaseTime class can be designed with a minimum number of elements to represent any required time. The design is based on the idea used in the real-time POSIX 1003.1b-1993 standard. That is, to represent time simply as a pair of integers: one for seconds (whole) and one for nanoseconds (fractional). These can then be converted at the interface level to any desired format.

   For ESMF, this idea can be modified and extended, in order to handle the requirements for a large time range (>$200,000$ years) and to exactly represent any rational fraction, not just nanoseconds. To handle the large time range, a 64-bit or greater integer is used for whole seconds. Any rational fractional second is expressed using two additional integers: a numerator and a denominator. Both the whole seconds and fractional numerator are signed to handle negative time intervals and instants. For arithmetic consistency both must carry the same sign (both positive or both negative), except, of course, for zero values. The fractional seconds element (numerator) is bounded with respect to whole seconds. If the absolute value of the numerator becomes greater than or equal to the denominator, whole seconds are incremented or decremented accordingly and the numerator is reset to the remainder. Conversions are performed upon demand by interface methods within the TimeInterval and Time classes. This is done because different applications require different representations of time intervals and time instances. Floating point values as well as integers can be specified for the various time units in the interfaces, see Table 39.4. Floating point values are represented internally as integer-based rational fractions.

   The BaseTime class defines increment and decrement methods for basic TimeInterval calculations between Time instants. It is done here rather than in the Calendar class because it can be done with simple second-based
arithmetic that is calendar independent. Comparison methods can also be defined in the BaseTime class. These perform equality/inequality, less than, and greater than comparisons between any two TimeIntervals or Times. These methods capture the common comparison logic between TimeIntervals and Times and hence are defined here for sharing.

2. **The Time class depends on a calendar.** The Time class contains an internal Calendar class. Upon demand by a user, the results of an increment or decrement operation are converted to user units, which may be calendar-dependent, via methods obtained from their internal Calendar.
39.6 Object Model

The following is a simplified UML diagram showing the structure of the Time Manager utility. See Appendix A, *A Brief Introduction to UML*, for a translation table that lists the symbols in the diagram and their meaning.
40 Calendar Class

40.1 Description

The Calendar class represents the standard calendars used in geophysical modeling: Gregorian, Julian, Julian Day, Modified Julian Day, no-leap, 360-day, and no-calendar. It also supports a user-customized calendar. Brief descriptions are provided for each calendar below. For more information on standard calendars, see [24] and [18].

40.2 Constants

40.2.1 ESMF_CALKIND

DESCRIPTION:
Supported calendar kinds.

The type of this flag is:

\[
\text{type(ESMF_Calkind_Flag)}
\]

The valid values are:

**ESMF_CALKIND_360DAY**  
*Valid range: machine limits*  
In the 360-day calendar, there are 12 months, each of which has 30 days. Like the no-leap calendar, this is a simple approximation to the Gregorian calendar sometimes used by modelers.

**ESMF_CALKIND_CUSTOM**  
*Valid range: machine limits*  
The user can set calendar parameters in the generic calendar.

**ESMF_CALKIND_GREGORIAN**  
*Valid range: 3/1/4801 BC to 10/29/292,277,019,914*  
The Gregorian calendar is the calendar currently in use throughout Western countries. Named after Pope Gregory XIII, it is a minor correction to the older Julian calendar. In the Gregorian calendar every fourth year is a leap year in which February has 29 and not 28 days; however, years divisible by 100 are not leap years unless they are also divisible by 400. As in the Julian calendar, days begin at midnight.

**ESMF_CALKIND_JULIAN**  
*Valid range: 3/1/4713 BC to 4/24/292,271,018,333*  
The Julian calendar was introduced by Julius Caesar in 46 B.C., and reached its final form in 4 A.D. The Julian calendar differs from the Gregorian only in the determination of leap years, lacking the correction for years divisible by 100 and 400 in the Gregorian calendar. In the Julian calendar, any year is a leap year if divisible by 4. Days are considered to begin at midnight.

**ESMF_CALKIND_JULIANDAY**  
*Valid range: +/- 1x10^{14}*  
Julian days simply enumerate the days and fraction of a day which have elapsed since the start of the Julian era, defined as beginning at noon on Monday, 1st January of year 4713 B.C. in the Julian calendar. Julian days, unlike the dates in the Julian and Gregorian calendars, begin at noon.

**ESMF_CALKIND_MODJULIANDAY**  
*Valid range: +/- 1x10^{14}*  
The Modified Julian Day (MJD) was introduced by space scientists in the late 1950’s. It is defined as an offset from the Julian Day (JD):

\[
\text{MJD} = \text{JD} - 2400000.5
\]

The half day is subtracted so that the day starts at midnight.
**ESMF_CALKIND_NOCALENDAR**  *Valid range: machine limits*

The no-calendar option simply tracks the elapsed model time in seconds.

**ESMF_CALKIND_NOLEAP**  *Valid range: machine limits*

The no-leap calendar is the Gregorian calendar with no leap years - February is always assumed to have 28 days. Modelers sometimes use this calendar as a simple, close approximation to the Gregorian calendar.

### 40.3 Use and Examples

In most multi-component Earth system applications, the timekeeping in each component must refer to the same standard calendar in order for the components to properly synchronize. It therefore makes sense to create as few ESMF Calendars as possible, preferably one per application. A typical strategy would be to create a single Calendar at the start of an application, and use that Calendar in all subsequent calls that accept a Calendar, such as `ESMF_TimeSet`.

The following example shows how to set up an ESMF Calendar:

```fortran
! PROGRAM: ESMF_CalendarEx - Calendar creation examples
!
! DESCRIPTION:
!
! This program shows examples of how to create different calendar kinds
!------------------------------------------------------------------------
#include "ESMF.h"

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! instantiate calendars
type(ESMF_Calendar) :: gregorianCalendar
type(ESMF_Calendar) :: julianDayCalendar
type(ESMF_Calendar) :: marsCalendar

! local variables for Get methods
integer :: sols
integer(ESMF_KIND_I8) :: dl
type(ESMF_Time) :: time, marsTime
type(ESMF_TimeInterval) :: marsTimeStep

! return code
integer:: rc

! initialize ESMF framework
call ESMF_Initialize(defaultlogfilename="CalendarEx.Log", &
logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

40.3.1 Calendar creation

This example shows how to create three ESMF_Calendars.
! create a Gregorian calendar
gregorianCalendar = ESMF_CalendarCreate(ESMF_CALKIND_GREGORIAN, &
    name="Gregorian", rc=rc)

! create a Julian Day calendar
julianDayCalendar = ESMF_CalendarCreate(ESMF_CALKIND_JULIANDAY, &
    name="JulianDay", rc=rc)

! create a Custom calendar for the planet Mars
! 1 Mars solar day = 24 hours, 39 minutes, 35 seconds = 88775 seconds
! 1 Mars solar year = 668.5921 Mars solar days = 668 5921/10000 sols/year
! http://www.giss.nasa.gov/research/briefs/allison_02
! http://www.giss.nasa.gov/tools/mars24/help/notes.html
marsCalendar = ESMF_CalendarCreate(secondsPerDay=88775, &
    daysPerYear=668, &
    daysPerYearDn=5921, &
    daysPerYearDd=10000, &
    name="MarsCalendar", rc=rc)

\section{Calendar comparison}

This example shows how to compare an \texttt{ESMF\_Calendar} with a known calendar kind.

! compare calendar kind against a known type
if (gregorianCalendar == ESMF_CALKIND_GREGORIAN) then
    print *, "gregorianCalendar is of type ESMF\_CALKIND\_GREGORIAN."
else
    print *, "gregorianCalendar is not of type ESMF\_CALKIND\_GREGORIAN."
end if

\section{Time conversion between Calendars}

This example shows how to convert a time from one \texttt{ESMF\_Calendar} to another.

call ESMF_TimeSet(time, yy=2004, mm=4, dd=17, &
    calendar=gregorianCalendar, rc=rc)

call ESMF_TimeGet(time, d_i8=dl, rc=rc)
print *, "Gregorian date 2004/4/17 is ", dl, &
    " days in the Julian Day calendar."
40.3.4 Add a time interval to a time on a Calendar

This example shows how to increment a time using a custom ESMF_Calendar.

! Set a time to Mars solar year 3, sol 100
call ESMF_TimeSet(marsTime, yy=3, d=100, &
    calendar=marsCalendar, rc=rc)

! Set a 1 solar year time step
call ESMF_TimeIntervalSet(marsTimeStep, yy=1, rc=rc)

! Perform the increment
marsTime = marsTime + marsTimeStep

! Get the result in sols (2774 = (3+1)*668.5921 + 100)
call ESMF_TimeGet(marsTime, d=sols, rc=rc)
print *, "For Mars, 3 solar years, 100 sols + 1 solar year = ", &
    sols, "sols."

40.3.5 Calendar destruction

This example shows how to destroy three ESMF_Calendars.

call ESMF_CalendarDestroy(julianDayCalendar, rc=rc)
call ESMF_CalendarDestroy(gregorianCalendar, rc=rc)
call ESMF_CalendarDestroy(marsCalendar, rc=rc)

! finalize ESMF framework
call ESMF_Finalize(rc=rc)
end program ESMF_CalendarEx

40.4 Restrictions and Future Work

1. Months per year set to 12. Due to the requirement of only Earth modeling, the number of months per year is hard-coded at 12. However, for easy modification, this is implemented via a C preprocessor #define MONTHS_PER_YEAR in ESMCI_Calendar.h.
2. **Calendar date conversions.** Date conversions are currently defined between the Gregorian, Julian, Julian Day, and Modified Julian Day calendars. Further research and work would need to be done to determine conversion algorithms with and between the other calendars: No Leap, 360 Day, and Custom.

3. **ESMF_CALKIND_CUSTOM.** Currently, there is no provision for a custom calendar to define a leap year rule, so ESMF_CalendarIsLeapYear() will always return .false. in this case. However, the arguments daysPerYear, daysPerYearDn, and daysPerYearDd in ESMF_CalendarCreate() and ESMF_CalendarSet() can be used to set a fractional number of days per year, for example, $365.25 = 365 \frac{25}{100}$. Also, if further timekeeping precision is required, fractional and/or floating point secondsPerDay and secondsPerYear could be added to the interfaces ESMF_CalendarCreate(), ESMF_CalendarSet(), and ESMF_CalendarGet() and implemented.

### 40.5 Class API

#### 40.5.1 ESMF_CalendarAssignment(=) - Assign a Calendar to another Calendar

**INTERFACE:**

```fortran
interface assignment(=)
   calendar1 = calendar2
end interface
```

**ARGUMENTS:**

- type(ESMF_Calendar) :: calendar1
- type(ESMF_Calendar) :: calendar2

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Assign `calendar1` as an alias to the same ESMF_Calendar object in memory as `calendar2`. If `calendar2` is invalid, then `calendar1` will be equally invalid after the assignment.

The arguments are:

- **calendar1** The ESMF_Calendar object on the left hand side of the assignment.
- **calendar2** The ESMF_Calendar object on the right hand side of the assignment.

#### 40.5.2 ESMF_CalendarOperator(==) - Test if Calendar argument 1 is equal to Calendar argument 2

**INTERFACE:**

```fortran
INTERFACE:
   interface operator(==)
      calendar1 == calendar2
   end interface
```

**ARGUMENTS:**

- type(ESMF_Calendar) :: calendar1
- type(ESMF_Calendar) :: calendar2

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Test if `calendar1` is equal to `calendar2`. If both are invalid, then the result is .false. Otherwise, the result is .true.

The arguments are:

- **calendar1** The ESMF_Calendar object on the left hand side of the assignment.
- **calendar2** The ESMF_Calendar object on the right hand side of the assignment.
interface operator(==)
if (<calendar argument 1> == <calendar argument 2>) then ... endif
OR
result = (<calendar argument 1> == <calendar argument 2>)

RETURN VALUE:

logical :: result

ARGUMENTS:

<calendar argument 1>, see below for supported values
<calendar argument 2>, see below for supported values

DESCRIPTION:

Overloads the (==) operator for the ESMF_Calendar class. Compare an ESMF_Calendar object or ESMF_CalKind_Flag with another calendar object or calendar kind for equality. Return .true. if equal, .false. otherwise. Comparison is based on calendar kind, which is a property of a calendar object.

If both arguments are ESMF_Calendar objects, and both are of type ESMF_CALKIND_CUSTOM, then all the calendar’s properties, except name, are compared.

If both arguments are ESMF_Calendar objects, and either of them is not in the ESMF_INIT_CREATED status, an error will be logged. However, this does not affect the return value, which is .true. when both arguments are in the same status, and .false. otherwise.

If one argument is an ESMF_Calendar object, and the other is an ESMF_CalKind_Flag, and the calendar object is not in the ESMF_INIT_CREATED status, an error will be logged and .false. will be returned.

Supported values for <calendar argument 1> are:

type(ESMF_Calendar), intent(in) :: calendar1
type(ESMF_CalKind_Flag), intent(in) :: calkindflag1

Supported values for <calendar argument 2> are:

type(ESMF_Calendar), intent(in) :: calendar2
type(ESMF_CalKind_Flag), intent(in) :: calkindflag2

The arguments are:

<calendar argument 1>  The ESMF_Calendar object or ESMF_CalKind_Flag on the left hand side of the equality operation.
<calendar argument 2>  The ESMF_Calendar object or ESMF_CalKind_Flag on the right hand side of the equality operation.
40.5.3  ESMF_CalendarOperator(/=) - Test if Calendar argument 1 is not equal to Calendar argument 2

INTERFACE:

    interface operator(/=)
    if (<calendar argument 1> /= <calendar argument 2>) then ... endif
    OR
    result = (<calendar argument 1> /= <calendar argument 2>)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    <calendar argument 1>, see below for supported values
    <calendar argument 2>, see below for supported values

DESCRIPTION:

Overloads the (=/=) operator for the ESMF_Calendar class. Compare a ESMF_Calendar object or ESMF_CalKind_Flag with another calendar object or calendar kind for inequality. Return .true. if not equal, .false. otherwise. Comparison is based on calendar kind, which is a property of a calendar object.

If both arguments are ESMF_Calendar objects, and both are of type ESMF_CalKind_FLAG_CUSTOM, then all the calendar’s properties, except name, are compared.

If both arguments are ESMF_Calendar objects, and either of them is not in the ESMF_INIT_CREATED status, an error will be logged. However, this does not affect the return value, which is .true. when both arguments are not in the same status, and .false. otherwise.

If one argument is an ESMF_Calendar object, and the other is an ESMF_CalKind_Flag, and the calendar object is not in the ESMF_INIT_CREATED status, an error will be logged and .true. will be returned.

Supported values for <calendar argument 1> are:

    type(ESMF_Calendar), intent(in) :: calendar1
    type(ESMF_CalKind_Flag), intent(in) :: calkindflag1

Supported values for <calendar argument 2> are:

    type(ESMF_Calendar), intent(in) :: calendar2
    type(ESMF_CalKind_Flag), intent(in) :: calkindflag2

The arguments are:

<calendar argument 1>  The ESMF_Calendar object or ESMF_CalKind_Flag on the left hand side of the non-equality operation.
<calendar argument 2>  The ESMF_Calendar object or ESMF_CalKind_Flag on the right hand side of the non-equality operation.
40.5.4 ESMF_CalendarCreate - Create a new ESMF Calendar of built-in type

INTERFACE:

! Private name; call using ESMF_CalendarCreate()
function ESMF_CalendarCreateBuiltIn(calkindflag, &
   name, rc)

RETURN VALUE:

    type(ESMF_Calendar) :: ESMF_CalendarCreateBuiltIn

ARGUMENTS:

    type(ESMF_CalKind_Flag), intent(in) :: calkindflag
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character (len= * ), intent(in), optional :: name
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Creates and sets a calendar to the given built-in ESMF_CalKind_Flag.
The arguments are:

calkindflag  The built-in ESMF_CalKind_Flag. Valid values are:
ESMF_CALKIND_360DAY,
ESMF_CALKIND_GREGORIAN,
ESMF_CALKIND_JULIAN,
ESMF_CALKIND_JULIANDAY,
ESMF_CALKIND_MODJULIANDAY,
ESMF_CALKIND_NOCALENDAR,
and ESMF_CALKIND_NOLEAP.
See Section 40.2 for a description of each calendar kind.

[name]  The name for the newly created calendar. If not specified, a default unique name will be generated: "CalendarNNN" where NNN is a unique sequence number from 001 to 999.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
40.5.5  ESMF_CalendarCreate - Create a copy of an ESMF Calendar

INTERFACE:

    ! Private name; call using ESMF_CalendarCreate()
    function ESMF_CalendarCreateCopy(calendar, rc)

RETURN VALUE:

    type(ESMF_Calendar) :: ESMF_CalendarCreateCopy

ARGUMENTS:

    type(ESMF_Calendar), intent(in) :: calendar
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Creates a complete (deep) copy of a given ESMF_Calendar.
The arguments are:

calendar  The ESMF_Calendar to copy.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

40.5.6  ESMF_CalendarCreate - Create a new custom ESMF Calendar

INTERFACE:

    ! Private name; call using ESMF_CalendarCreate()
    function ESMF_CalendarCreateCustom(&
        daysPerMonth, secondsPerDay, &
        daysPerYear, daysPerYearDn, daysPerYearDd, name, rc)

RETURN VALUE:
type(ESMF_Calendar) :: ESMF_CalendarCreateCustom

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: daysPerMonth(:)
integer(ESMF_KIND_I4), intent(in), optional :: secondsPerDay
integer(ESMF_KIND_I4), intent(in), optional :: daysPerYear
integer(ESMF_KIND_I4), intent(in), optional :: daysPerYearDn
integer(ESMF_KIND_I4), intent(in), optional :: daysPerYearDd
character (len=*), intent(in), optional :: name
integer, intent(out), optional :: rc

DESCRIPTION:

Creates a custom ESMF_Calendar and sets its properties.

The arguments are:

[daysPerMonth] Integer array of days per month, for each month of the year. The number of months per year is variable and taken from the size of the array. If unspecified, months per year = 0, with the days array undefined.

[secondsPerDay] Integer number of seconds per day. Defaults to 0 if not specified.

[daysPerYear] Integer number of days per year. Use with daysPerYearDn and daysPerYearDd (see below) to specify a days-per-year calendar for any planetary body. Default = 0.

[daysPerYearDn] Integer numerator portion of fractional number of days per year (daysPerYearDn/daysPerYearDd). Use with daysPerYear (see above) and daysPerYearDd (see below) to specify a days-per-year calendar for any planetary body. Default = 0.

[daysPerYearDd] Integer denominator portion of fractional number of days per year (daysPerYearDn/daysPerYearDd). Use with daysPerYear and daysPerYearDn (see above) to specify a days-per-year calendar for any planetary body. Default = 1.

[name] The name for the newly created calendar. If not specified, a default unique name will be generated: "CalendarNNN" where NNN is a unique sequence number from 001 to 999.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

40.5.7 ESMF_CalendarDestroy - Release resources associated with a Calendar

INTERFACE:

    subroutine ESMF_CalendarDestroy(calendar, rc)
type(ESMF_Calendar), intent(inout) :: calendar

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Releases resources associated with this ESMF_Calendar.

The arguments are:

calendar Release resources associated with this ESMF_Calendar and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.

[rc ] Return code; equals ESMF_SUCCESS if there are no errors.

40.5.8 ESMF_CalendarGet - Get Calendar properties

INTERFACE:

subroutine ESMF_CalendarGet(calendar, &
   name, calkindflag, daysPerMonth, monthsPerYear, &
   secondsPerDay, secondsPerYear, &
   daysPerYear, daysPerYearDn, daysPerYearDd, rc)

ARGUMENTS:

 type(ESMF_Calendar), intent(in) :: calendar
 -- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_CalKind_Flag), intent(out), optional :: calkindflag
integer, intent(out), optional :: daysPerMonth(:)
integer, intent(out), optional :: monthsPerYear
integer(ESMF_KIND_I4), intent(out), optional :: secondsPerDay
integer(ESMF_KIND_I4), intent(out), optional :: secondsPerYear
integer(ESMF_KIND_I4), intent(out), optional :: daysPerYear
integer(ESMF_KIND_I4), intent(out), optional :: daysPerYearDn
integer(ESMF_KIND_I4), intent(out), optional :: daysPerYearDd
character (len=*), intent(out), optional :: name
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Gets one or more of an ESMF_Calendar's properties.

The arguments are:

calendar  The object instance to query.

calKindFlag  The CalKind_Flag ESMF_CALKIND_GREGORIAN, ESMF_CALKIND_JULIAN, etc.

daysPerMonth  Integer array of days per month, for each month of the year.

monthsPerYear  Integer number of months per year; the size of the daysPerMonth array.

secondsPerDay  Integer number of seconds per day.

secondsPerYear  Integer number of seconds per year.

daysPerYear  Integer number of days per year. For calendars with intercalations, daysPerYear is the number of days for years without an intercalation. For other calendars, it is the number of days in every year.

daysPerYearDn  Integer fractional number of days per year (numerator). For calendars with intercalations, daysPerYearDn/daysPerYearDd is the average fractional number of days per year (e.g. 25/100 for Julian 4-year intercalation). For other calendars, it is zero.

daysPerYearDd  Integer fractional number of days per year (denominator). See daysPerYearDn above.

name  The name of this calendar.

rc  Return code; equals ESMF_SUCCESS if there are no errors.

40.5.9  ESMF_CalendarIsLeapYear - Determine if given year is a leap year

INTERFACE:

! Private name; call using ESMF_CalendarIsLeapYear()
function ESMF_CalendarIsLeapYear<kind>(calendar, yy, rc)

RETURN VALUE:

logical :: ESMF_CalendarIsLeapYear<kind>

ARGUMENTS:

type(ESMF_Calendar), intent(in) :: calendar

integer(ESMF_KIND_<kind>), intent(in) :: yy

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

integer, intent(out), optional :: rc

STATUS:
• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns .true. if the given year is a leap year within the given calendar, and .false. otherwise. Custom calendars do not define leap years, so .false. will always be returned in this case; see Section [40.4]. See also ESMF_TimeIsLeapYear().

The arguments are:

**calendar** ESMF_Calendar to determine leap year within.

**yy** Year to check for leap year. The type is integer and the <kind> can be either I4 or I8: ESMF_KIND_I4 or ESMF_KIND_I8.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

40.5.10  ESMF_CalendarPrint - Print Calendar information

INTERFACE:

```fortran
subroutine ESMF_CalendarPrint(calendar, options, rc)
```

ARGUMENTS:

```fortran
type(ESMF_Calendar), intent(in) :: calendar  :: calendar
character (len=*) , intent(in), optional :: options
integer, intent(out), optional :: rc
```

DESCRIPTION:

Prints out an ESMF_Calendar's properties to stdout, in support of testing and debugging. The options control the type of information and level of detail.

The arguments are:

**calendar** ESMF_Calendar to be printed out.

[options] Print options. If none specified, prints all calendar property values.
  "calkindflag" - print the calendar's type (e.g. ESMF_CALKIND_GREGORIAN).
  "daysPerMonth" - print the array of number of days for each month.
  "daysPerYear" - print the number of days per year (integer and fractional parts).
  "monthsPerYear" - print the number of months per year.
  "name" - print the calendar's name.
  "secondsPerDay" - print the number of seconds in a day.
  "secondsPerYear" - print the number of seconds in a year.
Return code; equals ESMF_SUCCESS if there are no errors.

---

### 40.5.11 ESMF_CalendarSet - Set a Calendar to a built-in type

**INTERFACE:**

```fortran
subroutine ESMF_CalendarSetBuiltIn(calendar, calcindflag, name, rc)
```

**ARGUMENTS:**

- `calendar`: type(ESMF_Calendar), intent(inout)
- `calcindflag`: type(ESMF_CalKind_Flag), intent(in)
- `name`: character (len=*), intent(in), optional
- `rc`: integer, intent(out), optional

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Sets `calendar` to the given built-in `ESMF_CalKind_Flag`.

The arguments are:

- **calendar**: The object instance to initialize.
- **calcindflag**: The built-in `CalKind_Flag`. Valid values are:
  
  ESMF_CALKIND_360DAY,
  ESMF_CALKIND_GREGORIAN,
  ESMF_CALKIND_JULIAN,
  ESMF_CALKIND_JULIANDAY,
  ESMF_CALKIND_MODJULIANDAY,
  ESMF_CALKIND_NOCALENDAR,
  and ESMF_CALKIND_NOLEAP.
  See Section 40.2 for a description of each calendar kind.

- **name**: The new name for this calendar.

- **rc**: Return code; equals ESMF_SUCCESS if there are no errors.
40.5.12  ESMF_CalendarSet - Set properties of a custom Calendar

INTERFACE:

! Private name; call using ESMF_CalendarSet()
subroutine ESMF_CalendarSetCustom(calendar, &
    daysPerMonth, secondsPerDay, &
    daysPerYear, daysPerYearDn, daysPerYearDd, name, rc)

ARGUMENTS:

type(ESMF_Calendar), intent(inout) :: calendar
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(in), optional :: daysPerMonth(:)
    integer(ESMF_KIND_I4),intent(in), optional :: secondsPerDay
    integer(ESMF_KIND_I4),intent(in), optional :: daysPerYear
    integer(ESMF_KIND_I4),intent(in), optional :: daysPerYearDn
    integer(ESMF_KIND_I4),intent(in), optional :: daysPerYearDd
    character (len= * ), intent(in), optional :: name
    integer, intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets properties in a custom ESMF_Calendar.

The arguments are:

calendar The object instance to initialize.

[daysPerMonth] Integer array of days per month, for each month of the year. The number of months per year is variable and taken from the size of the array. If unspecified, months per year = 0, with the days array undefined.

[secondsPerDay] Integer number of seconds per day. Defaults to 0 if not specified.

[daysPerYear] Integer number of days per year. Use with daysPerYearDn and daysPerYearDd (see below) to specify a days-per-year calendar for any planetary body. Default = 0.

[daysPerYearDn] Integer numerator portion of fractional number of days per year (daysPerYearDn/daysPerYearDd). Use with daysPerYear (see above) and daysPerYearDd (see below) to specify a days-per-year calendar for any planetary body. Default = 0.

[daysPerYearDd] Integer denominator portion of fractional number of days per year (daysPerYearDn/daysPerYearDd). Use with daysPerYear and daysPerYearDn (see above) to specify a days-per-year calendar for any planetary body. Default = 1.

[name] The new name for this calendar.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
40.5.13  ESMF_CalendarSetDefault - Set the default Calendar kind

INTERFACE:

    ! Private name; call using ESMF_CalendarSetDefault()
    subroutine ESMF_CalendarSetDefaultKind(calkindflag, rc)

ARGUMENTS:

    type(ESMF_CalKind_Flag), intent(in) :: calkindflag
    integer, intent(out), optional :: rc

DESCRIPTION:

Sets the default calendar to the given type. Subsequent Time Manager operations requiring a calendar where one isn’t specified will use the internal calendar of this type.

The arguments are:

    calkindflag  The calendar kind to be the default.
    [rc]  Return code; equals ESMF_SUCCESS if there are no errors.

40.5.14  ESMF_CalendarSetDefault - Set the default Calendar

INTERFACE:

    ! Private name; call using ESMF_CalendarSetDefault()
    subroutine ESMF_CalendarSetDefaultCal(calendar, rc)

ARGUMENTS:

    type(ESMF_Calendar), intent(in) :: calendar
    integer, intent(out), optional :: rc

DESCRIPTION:

Sets the default calendar to the one given. Subsequent Time Manager operations requiring a calendar where one isn’t specified will use this calendar.

The arguments are:

    calendar  The object instance to be the default.
    [rc]  Return code; equals ESMF_SUCCESS if there are no errors.
40.5.15 ESMF_CalendarValidate - Validate a Calendar’s properties

INTERFACE:

    subroutine ESMF_CalendarValidate(calendar, rc)

ARGUMENTS:

    type(ESMF_Calendar), intent(in) :: calendar
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Checks whether a calendar is valid. Must be one of the defined calendar kinds. daysPerMonth, daysPerYear, secondsPerDay must all be greater than or equal to zero.

The arguments are:

calendar ESMF_Calendar to be validated.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
41 Time Class

41.1 Description

A Time represents a specific point in time. In order to accommodate the range of time scales in Earth system applications, Times in the ESMF can be specified in many different ways, from years to nanoseconds. The Time interface is designed so that you select one or more options from a list of time units in order to specify a Time. The options for specifying a Time are shown in Table 39.4.

There are Time methods defined for setting and getting a Time, incrementing and decrementing a Time by a TimeInterval, taking the difference between two Times, and comparing Times. Special quantities such as the middle of the month and the day of the year associated with a particular Time can be retrieved. There is a method for returning the Time value as a string in the ISO 8601 format YYYY-MM-DDThh:mm:ss [15].

A Time that is specified in hours, minutes, seconds, or subsecond intervals does not need to be associated with a standard calendar; a Time whose specification includes time units of a day and greater must be. The ESMF representation of a calendar, the Calendar class, is described in Section 40.1. The ESMF_TimeSet method is used to initialize a Time as well as associate it with a Calendar. If a Time method is invoked in which a Calendar is necessary and one has not been set, the ESMF method will return an error condition.

In the ESMF the TimeInterval class is used to represent time periods. This class is frequently used in combination with the Time class. The Clock class, for example, advances model time by incrementing a Time with a TimeInterval.

41.2 Use and Examples

Times are most frequently used to represent start, stop, and current model times. The following examples show how to create, initialize, and manipulate Time.

! !PROGRAM: ESMF_TimeEx - Time initialization and manipulation examples
! !DESCRIPTION:
! ! This program shows examples of Time initialization and manipulation
!-------------------------------------------------- ---------------------------
#include "ESMF.h"

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! instantiate two times
type(ESMF_Time) :: time1, time2

type(ESMF_VM) :: vm

! instantiate a time interval
type(ESMF_TimeInterval) :: timeinterval1

! local variables for Get methods
integer :: YY, MM, DD, H, M, S
! return code
integer:: rc

! initialize ESMF framework
call ESMF_Initialize(vm=vm, defaultCalKind=ESMF_CALKIND_GREGORIAN, &
   defaultlogfilename="TimeEx.Log", &
   logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

41.2.1 Time initialization

This example shows how to initialize an ESMF_Time.

! initialize time1 to 2/28/2000 2:24:45
call ESMF_TimeSet(time1, yy=2000, mm=2, dd=28, h=2, m=24, s=45, rc=rc)

print *, "Time1 = 
call ESMF_TimePrint(time1, options="string", rc=rc)

41.2.2 Time increment

This example shows how to increment an ESMF_Time by an ESMF_TimeInterval.

! initialize a time interval to 2 days, 8 hours, 36 minutes, 15 seconds
call ESMF_TimeIntervalSet(timeinterval1, d=2, h=8, m=36, s=15, rc=rc)

print *, "Timeinterval1 = 
call ESMF_TimeIntervalPrint(timeinterval1, options="string", rc=rc)

! increment time1 with timeinterval1
time2 = time1 + timeinterval1
call ESMF_TimeGet(time2, yy=YY, mm=MM, dd=DD, h=H, m=M, s=S, rc=rc)
print *, "time2 = time1 + timeinterval1 = ", YY, "/", MM, "/", DD, &
   " ", H, ":", M, ":", S

41.2.3 Time comparison

This example shows how to compare two ESMF_Times.

if (time2 > time1) then
   print *, "time2 is larger than time1"
else

925
41.3 Restrictions and Future Work

1. Limits on size and resolution of Time. The limits on the size and resolution of the time representation are based on the 64-bit integer types used. For seconds, a signed 64-bit integer will have a range of $\pm 2^{63} - 1$, or $\pm 9,223,372,036,854,775,807$. This corresponds to a maximum size of $\pm (2^{63} - 1)/(86400 \times 365.25)$ or $\pm 292,271,023,045$ years.

   For fractional seconds, a signed 64-bit integer will handle a resolution of $\pm 2^{31} - 1$, or $\pm 9,223,372,036,854,775,807$ parts of a second.

41.4 Class API

41.4.1 ESMF_TimeAssignment(=) - Assign a Time to another Time

INTERFACE:

```fortran
interface assignment(=)
  time1 = time2
end interface
```

ARGUMENTS:

```fortran
  type(ESMF_Time) :: time1
  type(ESMF_Time) :: time2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Set `time1` equal to `time2`. This is the default Fortran assignment, which creates a complete, independent copy of `time2` as `time1`. If `time2` is an invalid ESMF_Time object then `time1` will be equally invalid after the assignment.

The arguments are:
time1  The ESMF_Time to be set.

time2  The ESMF_Time to be copied.

41.4.2 ESMF_TimeOperator(+) - Increment a Time by a TimeInterval

INTERFACE:

interface operator(+)
    time2 = time1 + timeinterval

RETURN VALUE:

type(ESMF_Time) :: time2

ARGUMENTS:

    type(ESMF_Time), intent(in) :: time1
    type(ESMF_TimeInterval), intent(in) :: timeinterval

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (+) operator for the ESMF_Time class to increment time1 with timeinterval and return the result as an ESMF_Time.

The arguments are:

time1  The ESMF_Time to increment.

timeinterval  The ESMF_TimeInterval to add to the given ESMF_Time.

41.4.3 ESMF_TimeOperator(-) - Decrement a Time by a TimeInterval

INTERFACE:

interface operator(-)
    time2 = time1 - timeinterval
41.4.4 ESMF_TimeOperator(-) - Return the difference between two Times

**INTERFACE:**

```fortran
interface operator(-)
  timeinterval = timel - time2
end interface
```

**RETURN VALUE:**

```fortran
type(ESMF_TimeInterval) :: timeinterval
```

**ARGUMENTS:**

```fortran
type(ESMF_Time), intent(in) :: timel
type(ESMF_Time), intent(in) :: time2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Overloads the (-) operator for the ESMF_Time class to return the difference between time1 and time2 as an ESMF_TimeInterval. It is assumed that time1 is later than time2; if not, the resulting ESMF_TimeInterval will have a negative value.

The arguments are:

**time1**  The first ESMF_Time in comparison.

**time2**  The second ESMF_Time in comparison.

### 41.4.5 ESMF_TimeOperator(==) - Test if Time 1 is equal to Time 2

**INTERFACE:**

```plaintext
interface operator(==)
if (time1 == time2) then ... endif
OR
result = (time1 == time2)
```

**RETURN VALUE:**

```plaintext
logical :: result
```

**ARGUMENTS:**

```plaintext
type(ESMF_Time), intent(in) :: time1

type(ESMF_Time), intent(in) :: time2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Overloads the (==) operator for the ESMF_Time class to return .true. if time1 and time2 represent the same instant in time, and .false. otherwise.

The arguments are:

**time1**  First ESMF_Time in comparison.

**time2**  Second ESMF_Time in comparison.
41.4.6 ESMF_TimeOperator(/=) - Test if Time 1 is not equal to Time 2

INTERFACE:

```plaintext
interface operator(/=)
  if (time1 /= time2) then ... endif
END INTERFACE
```

OR

```plaintext
result = (time1 /= time2)
```

RETURN VALUE:

logical :: result

ARGUMENTS:

- `time1` of type(
  ESMF_Time), intent(in)
- `time2` of type(
  ESMF_Time), intent(in)

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Overloads the (/=) operator for the ESMF_Time class to return .true. if `time1` and `time2` do not represent the same instant in time, and .false. otherwise.

The arguments are:

- `time1` First ESMF_Time in comparison.
- `time2` Second ESMF_Time in comparison.

41.4.7 ESMF_TimeOperator(<) - Test if Time 1 is less than Time 2

INTERFACE:

```plaintext
interface operator(<)
  if (time1 < time2) then ... endif
END INTERFACE
```

OR

```plaintext
result = (time1 < time2)
```

RETURN VALUE:

logical :: result
ARGUMENTS:

type(ESMF_Time), intent(in) :: time1
type(ESMF_Time), intent(in) :: time2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (<) operator for the ESMF_Time class to return .true. if time1 is earlier in time than time2, and .false. otherwise.

The arguments are:

- **time1** First ESMF_Time in comparison.
- **time2** Second ESMF_Time in comparison.

41.4.8 ESMF_TimeOperator(<=) - Test if Time 1 is less than or equal to Time 2

INTERFACE:

```
interface operator(<=)
  if (time1 <= time2) then ... endif
 OR
  result = (time1 <= time2)
end interface
```

RETURN VALUE:

```
logical :: result
```

ARGUMENTS:

type(ESMF_Time), intent(in) :: time1
type(ESMF_Time), intent(in) :: time2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (<=) operator for the ESMF_Time class to return .true. if time1 is earlier in time or the same time as time2, and .false. otherwise.

The arguments are:
time1  First ESMF_Time in comparison.

time2  Second ESMF_Time in comparison.

41.4.9  ESMF_TimeOperator(>) - Test if Time 1 is greater than Time 2

INTERFACE:

    interface operator(>)
    if (time1 > time2) then ... endif
    OR
    result = (time1 > time2)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_Time), intent(in) :: time1
    type(ESMF_Time), intent(in) :: time2

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (>) operator for the ESMF_Time class to return .true. if time1 is later in time than time2, and .false. otherwise.

The arguments are:

    time1  First ESMF_Time in comparison.
    time2  Second ESMF_Time in comparison.

41.4.10  ESMF_TimeOperator(>=) - Test if Time 1 is greater than or equal to Time 2

INTERFACE:

    interface operator(>=)
    if (time1 >= time2) then ... endif
    OR
    result = (time1 >= time2)
RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_Time), intent(in) :: time1
    type(ESMF_Time), intent(in) :: time2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (>=) operator for the ESMF_Time class to return .true. if time1 is later in time or the same time as time2, and .false. otherwise.

The arguments are:

- **time1** First ESMF_Time in comparison.
- **time2** Second ESMF_Time in comparison.

---

41.4.11 ESMF_TimeGet - Get a Time value

INTERFACE:

    subroutine ESMF_TimeGet(time, &
        yy, yy_i8, &
        mm, dd, &
        d, d_i8, &
        h, m, &
        s, s_i8, &
        ms, us, ns, &
        d_r8, h_r8, m_r8, s_r8, &
        ms_r8, us_r8, ns_r8, &
        sN, sN_i8, sD, sD_i8, &
        calendar, calkindflag, timeZone, &
        timeString, timeStringISOFrac, &
        dayOfWeek, midMonth, &
        dayOfYear, dayOfYear_r8, &
        dayOfYear_intvl, rc)

ARGUMENTS:
type(ESMF_Time), intent(in) :: time

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer(ESMF_KIND_I4), intent(out), optional :: yy
integer(ESMF_KIND_I8), intent(out), optional :: yy_i8
integer, intent(out), optional :: mm
integer, intent(out), optional :: dd
integer(ESMF_KIND_I4), intent(out), optional :: d
integer(ESMF_KIND_I8), intent(out), optional :: d_i8
integer(ESMF_KIND_I8), intent(out), optional :: h
integer(ESMF_KIND_I8), intent(out), optional :: m
integer(ESMF_KIND_I4), intent(out), optional :: s
integer(ESMF_KIND_I8), intent(out), optional :: s_i8

real(ESMF_KIND_R8), intent(out), optional :: us_r8
real(ESMF_KIND_R8), intent(out), optional :: ns_r8
integer(ESMF_KIND_I4), intent(out), optional :: sN
integer(ESMF_KIND_I8), intent(out), optional :: sN_i8
integer(ESMF_KIND_I4), intent(out), optional :: sD
integer(ESMF_KIND_I8), intent(out), optional :: sD_i8
type(ESMF_Calendar), intent(out), optional :: calendar
type(ESMF_CalKind_Flag), intent(out), optional :: calkindflag
integer, intent(out), optional :: timeZone ! not imp
character (len=*), intent(out), optional :: timeString
character (len=*), intent(out), optional :: timeStringISOFrac
integer, intent(out), optional :: dayOfWeek
type(ESMF_Time), intent(out), optional :: midMonth
integer(ESMF_KIND_I4), intent(out), optional :: dayOfYear
real(ESMF_KIND_R8), intent(out), optional :: dayOfYear_r8
type(ESMF_TimeInterval), intent(out), optional :: dayOfYear_intvl
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the value of time in units specified by the user via Fortran optional arguments. See ESMF_TimeSet() above for a description of time units and calendars.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally from integers. For example, if a time value is 5 and 3/8 seconds (s=5, sN=3, sD=8), and you want to get it as floating point seconds, you would get 5.375 (s_r8=5.375).

Units are bound (normalized) by the next larger unit specified. For example, if a time is defined to be 2:00 am on February 2, 2004, then ESMF_TimeGet(dd=day, h=hours, s=seconds) would return day = 2, hours
whereas ESMF_TimeGet(dd = day, s=seconds) would return day = 2, seconds = 7200. Note that hours and seconds are bound by a day. If bound by a month, ESMF_TimeGet(mm=month, h=hours, s=seconds) would return month = 2, hours = 26, seconds = 0, and ESMF_TimeGet(mm = month, s=seconds) would return month = 2, seconds = 93600 (26 * 3600). Similarly, if bound to a year, ESMF_TimeGet(yy=year, h=hours, s=seconds) would return year = 2004, hours = 770 (32*24 + 2), seconds = 0, and ESMF_TimeGet(yy = year, s=seconds) would return year = 2004, seconds = 2772000 (770 * 3600).

For timeString, timeStringISOFrac, dayOfWeek, midMonth, dayOfYear, dayOfYear_r8 described below, valid calendars are Gregorian, Julian, No Leap, 360 Day and Custom calendars. Not valid for Julian Day, Modified Julian Day, or No Calendar.

For timeString and timeStringISOFrac, YYYY format returns at least 4 digits; years <= 999 are padded on the left with zeroes and years >= 1000 return the number of digits required.

For timeString, convert ESMF_Time’s value into partial ISO 8601 format YYYY-MM-DDThh:mm:ss[ :n/d]. See [15] and [2]. See also method ESMF_TimePrint().

For timeStringISOFrac, convert ESMF_Time’s value into full ISO 8601 format YYYY-MM-DDThh:mm:ss[.f]. See [15] and [2]. See also method ESMF_TimePrint().

For dayOfWeek, gets the day of the week the given ESMF_Time instant falls on. ISO 8601 standard: Monday = 1 through Sunday = 7. See [15] and [2].

For midMonth, gets the middle time instant of the month that the given ESMF_Time instant falls on.

For dayOfYear, gets the day of the year that the given ESMF_Time instant falls on. See range discussion in argument list below. Return as an integer value.

For dayOfYear_r8, gets the day of the year the given ESMF_Time instant falls on. See range discussion in argument list below. Return as floating point value; fractional part represents the time of day.

For dayOfYear_intvl, gets the day of the year the given ESMF_Time instant falls on. Return as an ESMF_TimeInterval.

The arguments are:

time The object instance to query.

[yy] Integer year (32-bit).

[yy_i8] Integer year (large, 64-bit).

[mm] Integer month.

[dd] Integer day of the month.

[d] Integer Julian date, or Modified Julian date (32-bit).

[d_i8] Integer Julian date, or Modified Julian date (large, 64-bit).

[h] Integer hour.

[m] Integer minute.

[s] Integer second (32-bit).

[s_i8] Integer second (large, 64-bit).

[ms] Integer millisecond.

[us] Integer microsecond.
[ns] Integer nanosecond.
[d_r8] Double precision day.
[h_r8] Double precision hour.
[m_r8] Double precision minute.
[s_r8] Double precision second.
[ms_r8] Double precision millisecond.
[us_r8] Double precision microsecond.
[ns_r8] Double precision nanosecond.

[sN] Integer numerator of fractional second (sN/sD).
[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, <= 64-bit).
[sD] Integer denominator of fractional second (sN/sD).
[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, <= 64-bit).

[calendar] Associated Calendar.
[calkindflag] Associated CalKind_Flag.

[timeZone] Associated timezone (hours offset from UCT, e.g. EST = -5). (Not implemented yet).

[TimeString] Convert time value to format string YYYY-MM-DDThh:mm:ss[:n/d], where n/d is numerator/denominator of any fractional seconds and all other units are in ISO 8601 format. See [15] and [2]. See also method ESMF_TimePrint().

[TimeStringISOFrac] Convert time value to strict ISO 8601 format string YYYY-MM-DDThh:mm:ss.f, where f is decimal form of any fractional seconds. See [15] and [2]. See also method ESMF_TimePrint().

dayOfWeek] The time instant’s day of the week [1-7].

[MidMonth] The given time instant’s middle-of-the-month time instant.

dayOfYear_intvl] The ESMF_Time instant’s day of the year as an ESMF_TimeInterval.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
41.4.12 ESMF_TimeIsLeapYear - Determine if a Time is in a leap year

INTERFACE:

    function ESMF_TimeIsLeapYear(time, rc)

RETURN VALUE:

    logical :: ESMF_TimeIsLeapYear

ARGUMENTS:

    type(ESMF_Time), intent(in) :: time
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns .true. if given time is in a leap year, and .false. otherwise. See also ESMF_CalendarIsLeapYear().

The arguments are:

time  The ESMF_Time to check for leap year.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

41.4.13 ESMF_TimeIsSameCalendar - Compare Calendars of two Times

INTERFACE:

    function ESMF_TimeIsSameCalendar(time1, time2, rc)

RETURN VALUE:

    logical :: ESMF_TimeIsSameCalendar
ARGUMENTS:

```
type(ESMF_Time), intent(in) :: time1
type(ESMF_Time), intent(in) :: time2
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns .true. if the Calendars in these Times are the same, .false. otherwise.

The arguments are:

- `time1` The first `ESMF_Time` in comparison.
- `time2` The second `ESMF_Time` in comparison.
- `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.

41.4.14 ESMF_TimePrint - Print Time information

INTERFACE:

```
subroutine ESMF_TimePrint(time, options, rc)
```

ARGUMENTS:

```
type(ESMF_Time), intent(in) :: time
character (len=*) , intent(in), optional :: options
integer, intent(out), optional :: rc
```

DESCRIPTION:

Prints out the contents of an `ESMF_Time` to `stdout`, in support of testing and debugging. The options control the type of information and level of detail. For options "string" and "string isofrac", YYYY format returns at least 4 digits; years <= 999 are padded on the left with zeroes and years >= 10000 return the number of digits required.

The arguments are:

- `time` The `ESMF_Time` to be printed out.
[options] Print options. If none specified, prints all Time property values.

"string" - prints time's value in ISO 8601 format for all units through seconds. For any non-zero fractional seconds, prints in integer rational fraction form n/d. Format is YYYY-MM-DDThh:mm:ss[:n/d], where [:n/d] is the integer numerator and denominator of the fractional seconds value, if present. See [15] and [2]. See also method ESMF_TimeGet(..., timeString= , ...)

"string isofrac" - prints time's value in strict ISO 8601 format for all units, including any fractional seconds part. Format is YYYY-MM-DDThh:mm:ss[.f] where [.f] represents fractional seconds in decimal form, if present. See [15] and [2]. See also method ESMF_TimeGet(..., timeStringISOFrac= , ...)

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

41.4.15 ESMF_TimeSet - Initialize or set a Time

INTERFACE:

subroutine ESMF_TimeSet(time, &
   yy, yy_i8, &
   mm, dd, &
   d, d_i8, &
   h, m, &
   s, s_i8, &
   ms, us, ns, &
   d_r8, h_r8, m_r8, s_r8, &
   ms_r8, us_r8, ns_r8, &
   sN, sN_i8, sD, sD_i8, &
   calendar, calkindflag, &
   timeZone, rc)

ARGUMENTS:

type(ESMF_Time), intent(inout) :: time
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
   integer(ESMF_KIND_I4), intent(in), optional :: yy
   integer(ESMF_KIND_I8), intent(in), optional :: yy_i8
   integer, intent(in), optional :: mm
   integer, intent(in), optional :: dd
   integer(ESMF_KIND_I4), intent(in), optional :: d
   integer(ESMF_KIND_I8), intent(in), optional :: d_i8
   integer(ESMF_KIND_I4), intent(in), optional :: h
   integer(ESMF_KIND_I4), intent(in), optional :: m
   integer(ESMF_KIND_I4), intent(in), optional :: s
   integer(ESMF_KIND_I4), intent(in), optional :: ms
   integer(ESMF_KIND_I4), intent(in), optional :: s_i8
   integer(ESMF_KIND_I4), intent(in), optional :: us
   integer(ESMF_KIND_I4), intent(in), optional :: ns
   real(ESMF_KIND_R8), intent(in), optional :: d_r8
   real(ESMF_KIND_R8), intent(in), optional :: h_r8
   real(ESMF_KIND_R8), intent(in), optional :: m_r8
   real(ESMF_KIND_R8), intent(in), optional :: s_r8

939
real(ESMF_KIND_R8), intent(in), optional :: ms_r8
real(ESMF_KIND_R8), intent(in), optional :: us_r8
real(ESMF_KIND_R8), intent(in), optional :: ns_r8
integer(ESMF_KIND_I4), intent(in), optional :: sN
integer(ESMF_KIND_I8), intent(in), optional :: sN_i8
integer(ESMF_KIND_I4), intent(in), optional :: sD
integer(ESMF_KIND_I8), intent(in), optional :: sD_i8
type(ESMF_Calendar), intent(in), optional :: calendar
type(ESMF_CalKind_Flag), intent(in), optional :: calkindflag
integer, intent(in), optional :: timeZone ! not imp
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Initializes an ESMF_Time with a set of user-specified units via Fortran optional arguments.

The range of valid values for mm and dd depend on the calendar used. For Gregorian, Julian, and No-Leap calendars, mm is [1-12] and dd is [1-28,29,30, or 31], depending on the value of mm and whether yy or yy_i8 is a leap year. For the 360-day calendar, mm is [1-12] and dd is [1-30]. For Julian Day, Modified Julian Day, and No-Calendar, yy, yy_i8, mm, and dd are invalid inputs, since these calendars do not define them. When valid, the yy and yy_i8 arguments should be fully specified, e.g. 2003 instead of 03. yy and yy_i8 ranges are only limited by machine word size, except for the Gregorian and Julian calendars, where the lowest (proleptic) date limits are 3/1/-4800 and 3/1/-4712, respectively. This is a limitation of the Gregorian date-to-Julian day and Julian date-to-Julian day conversion algorithms used to convert Gregorian and Julian dates to the internal representation of seconds. See [11] for a description of the Gregorian date-to-Julian day algorithm and [14] for a description of the Julian date-to-Julian day algorithm. The Custom calendar will have user-defined values for yy, yy_i8, mm, and dd.

The Julian day specifier, d or d_i8, can only be used with the Julian Day and Modified Julian Day calendars, and has a valid range depending on the word size. For a signed 32-bit d, the range for Julian day is +/- 24855. For a signed 64-bit d_i8, the valid range for Julian day is +/- 106,751,991,167,300]. The Julian day number system adheres to the conventional standard where the reference day of d=0 corresponds to 11/24/-4713 in the proleptic Gregorian calendar and 1/1/-4712 in the proleptic Julian calendar. See [19] and [1].

The Modified Julian Day system, introduced by space scientists in the late 1950's, is defined as Julian Day - 2400000.5. See [26].

Note that d and d_i8 are not valid for the No-Calendar. To remain consistent with non-Earth calendars added to ESMF in the future, ESMF requires a calendar to be planet-specific. Hence the No-Calendar does not know what a day is; it cannot assume an Earth day of 86400 seconds.

Hours, minutes, seconds, and sub-seconds can be used with any calendar, since they are standardized units that are the same for any planet.

Time manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally to integers. Sub-second values are represented internally with an integer numerator and denominator fraction (sN/sD). The smallest required resolution is nanoseconds (denominator). For example, pi can be represented as s=3, sN=141592654, sD=1000000000. However, via sN_i8 and sD_i8, larger values can be used. If specifying a constant floating point value, be sure to provide at least 16 digits to take full advantage of double precision, for example s_r8=2.718281828459045d0 for 'e' seconds.

The arguments are:
time The object instance to initialize.

[yy] Integer year (32-bit). Default = 0.

[yy_i8] Integer year (large, 64-bit). Default = 0.

[mm] Integer month. Default = 1.

[dd] Integer day of the month. Default = 1.

[d_i8] Integer Julian Day, or Modified Julian Day (large, 64-bit). Must not be specified with Gregorian calendars. Default = 0.

[h] Integer hour. Default = 0.

[m] Integer minute. Default = 0.

[s] Integer second (32-bit). Default = 0.

[s_i8] Integer second (large, 64-bit). Default = 0.

[ms] Integer millisecond. Default = 0.

[us] Integer microsecond. Default = 0.

[ns] Integer nanosecond. Default = 0.

[d_r8] Double precision day. Default = 0.0.

[h_r8] Double precision hour. Default = 0.0.

[m_r8] Double precision minute. Default = 0.0.

[s_r8] Double precision second. Default = 0.0.

[ms_r8] Double precision millisecond. Default = 0.0.

[us_r8] Double precision microsecond. Default = 0.0.

[ns_r8] Double precision nanosecond. Default = 0.0.

[sN] Integer numerator of fractional second (sN/sD). Default = 0.

[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit). Default = 0.

[sD] Integer denominator of fractional second (sN/sD). Default = 1.

[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit). Default = 1.

[calendar] Associated Calendar. Defaults to calendar ESMF_CALKIND_NOCALENDAR or default specified in ESMF_Initialize() or ESMF_CalendarSetDefault(). Alternate to, and mutually exclusive with, calkindflag below. Primarily for specifying a custom calendar kind.

[calkindflag] Alternate to, and mutually exclusive with, calendar above. More convenient way of specifying a built-in calendar kind.

[timeZone] Associated timezone (hours offset from UTC, e.g. EST = -5). Default = 0 (UTC). (Not implemented yet).

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
41.4.16 ESMF_TimeSyncToRealTime - Get system real time (wall clock time)

INTERFACE:

    subroutine ESMF_TimeSyncToRealTime(time, rc)

ARGUMENTS:

    type(ESMF_Time), intent(inout) :: time
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the system real time (wall clock time), and returns it as an ESMF_Time. Accurate to the nearest second.

The arguments are:

time  The object instance to receive the real time.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

41.4.17 ESMF_TimeValidate - Validate a Time

INTERFACE:

    subroutine ESMF_TimeValidate(time, options, rc)

ARGUMENTS:

    type(ESMF_Time), intent(in) :: time
    character (len=*) , intent(in), optional :: options
    integer, intent(out), optional :: rc

DESCRIPTION:

Checks whether an ESMF_Time is valid. Must be a valid date/time on a valid calendar. The options control the type of validation.

The arguments are:
time  ESMF_Time instant to be validated.

[options] Validation options. If none specified, validates all time property values.
   "calendar" - validate only the time’s calendar.
   "timezone" - validate only the time’s timezone.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
42 TimeInterval Class

42.1 Description

A TimeInterval represents a period between time instants. It can be either positive or negative. Like the Time interface, the TimeInterval interface is designed so that you can choose one or more options from a list of time units in order to specify a TimeInterval. See Section 39.3 Table 39.4 for the available options.

There are TimeInterval methods defined for setting and getting a TimeInterval, for incrementing and decrementing a TimeInterval by another TimeInterval, and for multiplying and dividing TimeIntervals by integers, reals, fractions and other TimeIntervals. Methods are also defined to take the absolute value and negative absolute value of a TimeInterval, and for comparing the length of two TimeIntervals.

The class used to represent time instants in ESMF is Time, and this class is frequently used in operations along with TimeIntervals. For example, the difference between two Times is a TimeInterval.

When a TimeInterval is used in calculations that involve an absolute reference time, such as incrementing a Time with a TimeInterval, calendar dependencies may be introduced. The length of the time period that the TimeInterval represents will depend on the reference Time and the standard calendar that is associated with it. The calendar dependency becomes apparent when, for example, adding a TimeInterval of 1 day to the Time of February 28, 1996, at 4:00pm EST. In a 360 day calendar, the resulting date would be February 29, 1996, at 4:00pm EST. In a no-leap calendar, the result would be March 1, 1996, at 4:00pm EST.

TimeIntervals are used by other parts of the ESMF timekeeping system, such as Clocks (Section 43.1) and Alarms (Section 44.1).

42.2 Use and Examples

A typical use for a TimeInterval in a geophysical model is representation of the time step by which the model is advanced. Some models change the size of their time step as the model run progresses; this could be done by incrementing or decrementing the original time step by another TimeInterval, or by dividing or multiplying the time step by an integer value. An example of advancing model time using a TimeInterval representation of a time step is shown in Section 43.1.

The following brief example shows how to create, initialize and manipulate TimeInterval.

```fortran
! PROGRAM: ESMF_TimeIntervalEx - Time Interval initialization and manipulation examples
!
! DESCRIPTION:
!
! This program shows examples of Time Interval initialization and manipulation
!------------------------------------------------------------------------------------------------------------------
#include "ESMF.h"

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! instantiate some time intervals
type(ESMF_TimeInterval) :: timeinterval1, timeinterval2, timeinterval3
```
! local variables
integer :: d, h, m, s

! return code
integer:: rc

! initialize ESMF framework
call ESMF_Initialize(defaultCalKind=ESMF_CALKIND_GREGORIAN, &
   defaultLogfilename="TimeIntervalEx.Log", &
   logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

### 42.2.1 TimeInterval initialization

This example shows how to initialize two ESMF_TimeIntervals.

! initialize time interval1 to 1 day
call ESMF_TimeIntervalSet(timeinterval1, d=1, rc=rc)

call ESMF_TimeIntervalPrint(timeinterval1, options="string", rc=rc)

! initialize time interval2 to 4 days, 1 hour, 30 minutes, 10 seconds
call ESMF_TimeIntervalSet(timeinterval2, d=4, h=1, m=30, s=10, rc=rc)

call ESMF_TimeIntervalPrint(timeinterval2, options="string", rc=rc)

### 42.2.2 TimeInterval conversion

This example shows how to convert ESMF_TimeIntervals into different units.

call ESMF_TimeIntervalGet(timeinterval1, s=s, rc=rc)
print *, "Time Interval1 = ", s, " seconds."

call ESMF_TimeIntervalGet(timeinterval2, h=h, m=m, s=s, rc=rc)
print *, "Time Interval2 = ", h, " hours, ", m, " minutes, ", 
   &
   s, " seconds."

### 42.2.3 TimeInterval difference

This example shows how to calculate the difference between two ESMF_TimeIntervals.
! difference between two time intervals
timeinterval3 = timeinterval2 - timeinterval1
call ESMF_TimeIntervalGet(timeinterval3, d=d, h=h, m=m, s=s, rc=rc)
print *, "Difference between TimeInterval2 and TimeInterval1 = ", 
  d, " days, ", h, " hours, ", m, " minutes, ", s, " seconds."

42.2.4 TimeInterval multiplication

This example shows how to multiply an ESMF_TimeInterval.

! multiply time interval by an integer
timeinterval3 = timeinterval2 * 3
call ESMF_TimeIntervalGet(timeinterval3, d=d, h=h, m=m, s=s, rc=rc)
print *, "TimeInterval2 multiplied by 3 = ", d, " days, ", h, &
  " hours, ", m, " minutes, ", s, " seconds."

42.2.5 TimeInterval comparison

This example shows how to compare two ESMF_TimeIntervals.

! comparison
if (timeinterval1 < timeinterval2) then
  print *, "TimeInterval1 is smaller than TimeInterval2"
else
  print *, "TimeInterval1 is larger than or equal to TimeInterval2"
end if

end program ESMF_TimeIntervalEx

42.3 Restrictions and Future Work

1. Limits on time span. The limits on the time span that can be represented are based on the 64-bit integer types used. For seconds, a signed 64-bit integer will have a range of +/- $2^{63} \cdot 1$, or +/- 9,223,722,816,251,095,615. This corresponds to a range of +/- ($2^{61} \cdot 1$)(86400 * 365.25) or +/- 292,271,023,045 years.

For fractional seconds, a signed 64-bit integer will handle a resolution of +/- $2^{31} \cdot 1$, or +/- 9,223,722,816,251,095,615 parts of a second.

42.4 Class API

42.4.1 ESMF_TimeIntervalAssignment(=) - Assign a TimeInterval to another TimeInterval

INTERFACE:
interface assignment (=)
timeintervall = timeinterval2

ARGUMENTS:

  type(ESMF_TimeInterval) :: timeintervall
  type(ESMF_TimeInterval) :: timeinterval2

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Set `timeintervall` equal to `timeinterval2`. This is the default Fortran assignment, which creates a complete, independent copy of `timeinterval2` as `timeintervall`. If `timeinterval2` is an invalid ESMF_TimeInterval object then `timeintervall` will be equally invalid after the assignment.

The arguments are:

  * `timeintervall` The ESMF_TimeInterval to be set.
  * `timeinterval2` The ESMF_TimeInterval to be copied.

-------

42.4.2 ESMF_TimeIntervalOperator(+) - Add two TimeIntervals

INTERFACE:

    interface operator (+)
    sum = timeintervall + timeinterval2

RETURN VALUE:

    type(ESMF_TimeInterval) :: sum

ARGUMENTS:

  type(ESMF_TimeInterval), intent(in) :: timeintervall
  type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Overloads the (+) operator for the ESMF_TimeInterval class to add timeinterval1 to timeinterval2 and return the sum as an ESMF_TimeInterval.

The arguments are:

timeinterval1  The augend.
timeinterval2  The addend.

42.4.3 ESMF_TimeIntervalOperator(-) - Subtract one TimeInterval from another

INTERFACE:

interface operator(-)
difference = timeinterval1 - timeinterval2

RETURN VALUE:

type(ESMF_TimeInterval) :: difference

ARGUMENTS:

type(ESMF_TimeInterval), intent(in) :: timeinterval1
type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (-) operator for the ESMF_TimeInterval class to subtract timeinterval2 from timeinterval1 and return the difference as an ESMF_TimeInterval.

The arguments are:

timeinterval1  The minuend.
timeinterval2  The subtrahend.
42.4.4 ESMF_TimeIntervalOperator(-) - Perform unary negation on a TimeInterval

INTERFACE:

interface operator(-)
  timeinterval = -timeinterval

RETURN VALUE:

  type(ESMF_TimeInterval) :: -timeInterval

ARGUMENTS:

  type(ESMF_TimeInterval), intent(in) :: timeinterval

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (-) operator for the ESMF_TimeInterval class to perform unary negation on timeinterval and return the result.

The arguments are:

timeinterval The time interval to be negated.

42.4.5 ESMF_TimeIntervalOperator(/) - Divide two TimeIntervals, return double precision quotient

INTERFACE:

interface operator(/)
  quotient = timeinterval1 / timeinterval2

RETURN VALUE:

  real(ESMF_KIND_R8) :: quotient

ARGUMENTS:

  type(ESMF_TimeInterval), intent(in) :: timeinterval1
  type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:
DESCRIPTION:

Overloads the (/) operator for the ESMF_TimeInterval class to return timeinterval1 divided by timeinterval2 as a double precision quotient.

The arguments are:

`timeinterval1` The dividend.

`timeinterval2` The divisor.

```plaintext
42.4.6 ESMF_TimeIntervalOperator(/) - Divide a TimeInterval by an integer, return TimeInterval quotient

INTERFACE:

```interface operator(/)
quotient = timeinterval / divisor```

RETURN VALUE:

```
type(ESMF_TimeInterval) :: quotient
```

ARGUMENTS:

```
type(ESMF_TimeInterval), intent(in) :: timeinterval
integer(ESMF_KIND_I4), intent(in) :: divisor
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (/) operator for the ESMF_TimeInterval class to divide a timeinterval by an integer divisor, and return the quotient as an ESMF_TimeInterval.

The arguments are:

`timeinterval` The dividend.

`divisor` Integer divisor.
42.4.7  ESMF_TimeIntervalFunction(MOD) - Divide two TimeIntervals, return TimeInterval remainder

INTERFACE:

    interface MOD
    function MOD(timeinterval1, timeinterval2)
    RETURN VALUE:

    type(ESMF_TimeInterval) :: MOD

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval1
    type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the Fortran intrinsic MOD() function for the ESMF_TimeInterval class to return the remainder of timeinterval1 divided by timeinterval2 as an ESMF_TimeInterval.

The arguments are:

    timeinterval1  The dividend.
    timeinterval2  The divisor.

42.4.8  ESMF_TimeIntervalOperator(*) - Multiply a TimeInterval by an integer

INTERFACE:

    interface operator(*)
    product = timeinterval * multiplier
    OR
    product = multiplier * timeinterval
    RETURN VALUE:

    type(ESMF_TimeInterval) :: product

ARGUMENTS:
type(ESMF_TimeInterval), intent(in) :: timeinterval
integer(ESMF_KIND_I4), intent(in) :: multiplier

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (*) operator for the ESMF_TimeInterval class to multiply a timeinterval by an integer multiplier, and return the product as an ESMF_TimeInterval.

The arguments are:

- `timeinterval` The multiplicand.
- `multiplier` The integer multiplier.

### 42.4.9 ESMF_TimeIntervalOperator(==) - Test if TimeInterval 1 is equal to TimeInterval 2

INTERFACE:

```fortran
interface operator(==)
  if (timeinterval1 == timeinterval2) then ... endif
  OR
  result = (timeinterval1 == timeinterval2)
end interface
```

RETURN VALUE:

- `logical :: result`

ARGUMENTS:

```fortran
  type(ESMF_TimeInterval), intent(in) :: timeinterval1
  type(ESMF_TimeInterval), intent(in) :: timeinterval2
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (==) operator for the ESMF_TimeInterval class to return `.true.` if `timeinterval1` and `timeinterval2` represent an equal duration of time, and `.false.` otherwise.

The arguments are:
42.4.10  ESMF_TimeIntervalOperator(/=) - Test if TimeInterval 1 is not equal to TimeInterval 2

INTERFACE:

    interface operator(/=)
      if (timeinterval1 /= timeinterval2) then ... endif
    OR
      result = (timeinterval1 /= timeinterval2)
    end

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval1
    type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (/=) operator for the ESMF_TimeInterval class to return .true. if timeinterval1 and timeinterval2 do not represent an equal duration of time, and .false. otherwise.

The arguments are:

    timeinterval1  First ESMF_TimeInterval in comparison.
    timeinterval2  Second ESMF_TimeInterval in comparison.

42.4.11  ESMF_TimeIntervalOperator(<) - Test if TimeInterval 1 is less than TimeInterval 2

INTERFACE:

    interface operator(<)
      if (timeinterval1 < timeinterval2) then ... endif
    OR
      result = (timeinterval1 < timeinterval2)
    end

The arguments are:

    timeinterval1  First ESMF_TimeInterval in comparison.
    timeinterval2  Second ESMF_TimeInterval in comparison.
RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval1
    type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (<) operator for the ESMF_TimeInterval class to return .true. if timeinterval1 is a lesser duration of time than timeinterval2, and .false. otherwise.

The arguments are:

    timeinterval1  First ESMF_TimeInterval in comparison.
    timeinterval2  Second ESMF_TimeInterval in comparison.

42.4.12 ESMF_TimeIntervalOperator(<=) - Test if TimeInterval 1 is less than or equal to TimeInterval 2

INTERFACE:

    interface operator(<=)
    if (timeinterval1 <= timeinterval2) then ... endif
    OR
    result = (timeinterval1 <= timeinterval2)

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval1
    type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Overloads the (\(<=\)) operator for the ESMF_TimeInterval class to return .true. if timeinterval1 is a lesser or equal duration of time than timeinterval2, and .false. otherwise.

The arguments are:

\textbf{timeinterval1} First ESMF_TimeInterval in comparison.
\textbf{timeinterval2} Second ESMF_TimeInterval in comparison.

\section*{42.4.13 ESMF_TimeIntervalOperator(\(>)\) - Test if TimeInterval 1 is greater than TimeInterval 2}

INTERFACE:

\begin{verbatim}
interface operator(>)
if (timeinterval1 > timeinterval2) then ... endif
OR
result = (timeinterval1 > timeinterval2)
\end{verbatim}

\textbf{RETURN VALUE}:

\textbf{logical :: result}

\textbf{ARGUMENTS}:

\begin{verbatim}
type(ESMF_TimeInterval), intent(in) :: timeinterval1
type(ESMF_TimeInterval), intent(in) :: timeinterval2
\end{verbatim}

\textbf{STATUS}:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

\textbf{DESCRIPTION}:

Overloads the (\(>\)) operator for the ESMF_TimeInterval class to return .true. if timeinterval1 is a greater duration of time than timeinterval2, and .false. otherwise.

The arguments are:

\textbf{timeinterval1} First ESMF_TimeInterval in comparison.
\textbf{timeinterval2} Second ESMF_TimeInterval in comparison.
42.4.14  ESMF_TimeIntervalOperator(==) - Test if TimeInterval 1 is greater than or equal to TimeInterval 2

INTERFACE:

interface operator(==)
  if (timeinterval1 == timeinterval2) then ... endif
  OR
  result = (timeinterval1 == timeinterval2)
end interface

RETURN VALUE:

logical :: result

ARGUMENTS:

  type(ESMF_TimeInterval), intent(in) :: timeinterval1
  type(ESMF_TimeInterval), intent(in) :: timeinterval2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Overloads the (==) operator for the ESMF_TimeInterval class to return .true. if timeinterval1 is a greater or equal duration of time than timeinterval2, and .false. otherwise. The arguments are:

  timeinterval1  First ESMF_TimeInterval in comparison.
  timeinterval2  Second ESMF_TimeInterval in comparison.

42.4.15  ESMF_TimeIntervalAbsValue - Get the absolute value of a TimeInterval

INTERFACE:

function ESMF_TimeIntervalAbsValue(timeinterval)

RETURN VALUE:

  type(ESMF_TimeInterval) :: ESMF_TimeIntervalAbsValue

ARGUMENTS:
type(ESMF_TimeInterval), intent(in) :: timeinterval

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns the absolute value of timeinterval.

The argument is:

timeinterval  The object instance to take the absolute value of. Absolute value is returned as the value of the function.

42.4.16  ESMF_TimeIntervalGet - Get a TimeInterval value

INTERFACE:

! Private name; call using ESMF_TimeIntervalGet()
subroutine ESMF_TimeIntervalGetDur(timeinterval, &
  yy, yy_i8, &
  mm, mm_i8, &
  d, d_i8, &
  h, m, &
  s, s_i8, &
  ms, us, ns, &
  d_r8, h_r8, m_r8, s_r8, &
  ms_r8, us_r8, ns_r8, &
  sN, sN_i8, sD, sD_i8, &
  startTime, calendar, calkindflag, &
timeString, timeStringISOFrac, rc)

ARGUMENTS:

type(ESMF_TimeInterval), intent(in) :: timeinterval

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer(ESMF_KIND_I4), intent(out), optional :: yy
  integer(ESMF_KIND_I8), intent(out), optional :: yy_i8
  integer(ESMF_KIND_I4), intent(out), optional :: mm
  integer(ESMF_KIND_I8), intent(out), optional :: mm_i8
  integer(ESMF_KIND_I4), intent(out), optional :: d
  integer(ESMF_KIND_I4), intent(out), optional :: d_i8
  integer(ESMF_KIND_I4), intent(out), optional :: h
  integer(ESMF_KIND_I4), intent(out), optional :: m
  integer(ESMF_KIND_I4), intent(out), optional :: s
  integer(ESMF_KIND_I8), intent(out), optional :: s_i8
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the value of \texttt{timeinterval} in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally from integers.

Units are bound (normalized) to the next larger unit specified. For example, if a time interval is defined to be one day, then \texttt{ESMF_TimeIntervalGet(d = days, s = seconds)} would return \( \text{days} = 1 \), \( \text{seconds} = 0 \), whereas \texttt{ESMF_TimeIntervalGet(s = seconds)} would return \( \text{seconds} = 86400 \).

For \texttt{timeString}, converts \texttt{ESMF_TimeInterval}'s value into partial ISO 8601 format \( \text{PyYmMdDThHmMs}[:n/d]S \). See [15] and [2]. See also method \texttt{ESMF_TimeIntervalPrint()}. For \texttt{timeStringISOFraction}, converts \texttt{ESMF_TimeInterval}'s value into full ISO 8601 format \( \text{PyYmMdDThHmMs[f]S} \). See [15] and [2]. See also method \texttt{ESMF_TimeIntervalPrint()}.

The arguments are:

- \texttt{timeinterval} The object instance to query.
- \( [\text{yy}] \) Integer year (32-bit).
- \( [\text{yy_i8}] \) Integer year (large, 64-bit).
- \( [\text{mm}] \) Integer month (32-bit).
- \( [\text{mm_i8}] \) Integer month (large, 64-bit).
- \( [\text{d}] \) Integer Julian day, or Modified Julian day (32-bit).
[d_i8]  Integer Julian day, or Modified Julian day (large, 64-bit).
[h]  Integer hour.
[m]  Integer minute.
[s]  Integer second (32-bit).
[s_i8]  Integer second (large, 64-bit).
[ms]  Integer millisecond.
[us]  Integer microsecond.
[ns]  Integer nanosecond.
[d_r8]  Double precision day.
[h_r8]  Double precision hour.
[m_r8]  Double precision minute.
[s_r8]  Double precision second.
[ms_r8]  Double precision millisecond.
[us_r8]  Double precision microsecond.
[ns_r8]  Double precision nanosecond.
[sN]  Integer numerator of fractional second (sN/sD).
[sN_i8]  Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[sD]  Integer denominator of fractional second (sN/sD).
[sD_i8]  Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[startTime]  Starting time, if set, of an absolute calendar interval (yy, mm, and/or d).
[calendar]  Associated Calendar, if any.
[calkindflag]  Associated CalKind_Flag, if any.
[TimeString]  Convert time interval value to format string PyYmMdDThHmMs[:n/d]S, where n/d is numerator/denominator of any fractional seconds and all other units are in ISO 8601 format. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[TimeStringISOfrac]  Convert time interval value to strict ISO 8601 format string PyYmMdDThHmMs[f], where f is decimal form of any fractional seconds. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
42.4.17  ESMF_TimeIntervalGet - Get a TimeInterval value

INTERFACE:

! Private name; call using ESMF_TimeIntervalGet()
subroutine ESMF_TimeIntervalGetDurStart(timeinterval, startTimeIn, &
  &
  yy, yy_i8, &
  mm, mm_i8, &
  d, d_i8, &
  h, m, &
  s, s_i8, &
  ms, us, ns, &
  d_r8, h_r8, m_r8, s_r8, &
  ms_r8, us_r8, ns_r8, &
  sN, sN_i8, sD, sD_i8, &
  startTime, &
  calendar, calkindflag, &
  timeString, timeStringISOFrac, rc)

ARGUMENTS:

type(ESMF_TimeInterval), intent(in) :: timeinterval

type(ESMF_Time), intent(in) :: startTimeIn ! Input

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer(ESMF_KIND_I4), intent(out), optional :: yy
integer(ESMF_KIND_I8), intent(out), optional :: yy_i8
integer(ESMF_KIND_I4), intent(out), optional :: mm
integer(ESMF_KIND_I8), intent(out), optional :: mm_i8
integer(ESMF_KIND_I4), intent(out), optional :: d
integer(ESMF_KIND_I8), intent(out), optional :: d_i8
integer(ESMF_KIND_I4), intent(out), optional :: h
integer(ESMF_KIND_I4), intent(out), optional :: m
integer(ESMF_KIND_I4), intent(out), optional :: s
integer(ESMF_KIND_I8), intent(out), optional :: s_i8
integer(ESMF_KIND_I4), intent(out), optional :: ms
integer(ESMF_KIND_I4), intent(out), optional :: us
integer(ESMF_KIND_I4), intent(out), optional :: ns
real(ESMF_KIND_R8), intent(out), optional :: d_r8
real(ESMF_KIND_R8), intent(out), optional :: h_r8
real(ESMF_KIND_R8), intent(out), optional :: m_r8

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the value of `timeinterval` in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally from integers.

Units are bound (normalized) to the next larger unit specified. For example, if a time interval is defined to be one day, then `ESMF_TimeIntervalGet(d = days, s = seconds)` would return `days = 1, seconds = 0`, whereas `ESMF_TimeIntervalGet(s = seconds)` would return `seconds = 86400`.

For `timeString`, converts `ESMF_TimeInterval`’s value into partial ISO 8601 format `PyYmMdDThHmMs[:n/d]S`. See [15] and [2]. See also method `ESMF_TimeIntervalPrint()`.

For `timeStringISOFrac`, converts `ESMF_TimeInterval`’s value into full ISO 8601 format `PyYmMdDThHmMs[.f]S`. See [15] and [2]. See also method `ESMF_TimeIntervalPrint()`.

The arguments are:

- `timeinterval` The object instance to query.
- `startTimeIn` INPUT argument: pins a calendar interval to a specific point in time to allow conversion between relative units (yy, mm, d) and absolute units (d, h, m, s). Overrides any startTime and/or endTime previously set. Mutually exclusive with endTimeIn and calendarIn.

  - `[yy]` Integer year (32-bit).
  - `[yy_i8]` Integer year (large, 64-bit).
  - `[mm]` Integer month (32-bit).
  - `[mm_i8]` Integer month (large, 64-bit).
  - `[d]` Integer Julian day, or Modified Julian day (32-bit).
  - `[d_i8]` Integer Julian day, or Modified Julian day (large, 64-bit).
  - `[h]` Integer hour.
  - `[m]` Integer minute.
  - `[s]` Integer second (32-bit).
  - `[s_i8]` Integer second (large, 64-bit).
  - `[ms]` Integer millisecond.
  - `[us]` Integer microsecond.
  - `[ns]` Integer nanosecond.
[d_r8] Double precision day.
[h_r8] Double precision hour.
[m_r8] Double precision minute.
[s_r8] Double precision second.
[ms_r8] Double precision millisecond.
[us_r8] Double precision microsecond.
[ns_r8] Double precision nanosecond.
[sN] Integer numerator of fractional second (sN/sD).
[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[sD] Integer denominator of fractional second (sN/sD).
[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[startTime] Starting time, if set, of an absolute calendar interval (yy, mm, and/or d).
[calendar] Associated Calendar, if any.
[calkindflag] Associated CalKind_Flag, if any.
[timeString] Convert time interval value to format string PyYmMdDThHmMs[:n/d]S, where n/d is numerator/denominator of any fractional seconds and all other units are in ISO 8601 format. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[TimeStringISOFrac] Convert time interval value to strict ISO 8601 format string PyYmMdDThHmMs[f], where f is decimal form of any fractional seconds. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

42.4.18 ESMF_TimeIntervalGet - Get a TimeInterval value

INTERFACE:

! Private name; call using ESMF_TimeIntervalGet()
subroutine ESMF_TimeIntervalGetDurCal(timeinterval, calendarIn, &
  &
  yy, yy_i8, &
  mm, mm_i8, &
  d, d_i8, &
  h, m, &
  s, s_i8, &
  ms, us, ns, &
  d_r8, h_r8, m_r8, s_r8, &
  ms_r8, us_r8, ns_r8, &
  sN, sN_i8, sD, sD_i8, &
  startTime, &
  calendar, calkindflag, &
  timeString, timeStringISOFrac, rc)
ARGUMENTS:

```fortran
type(ESMF_TimeInterval), intent(in) :: timeinterval

--- The following arguments require argument keyword syntax (e.g. rc=rc). ---
integer(ESMF_KIND_I4), intent(out), optional :: yy
integer(ESMF_KIND_I8), intent(out), optional :: yy_i8

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the value of `timeinterval` in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally from integers.

Units are bound (normalized) to the next larger unit specified. For example, if a time interval is defined to be one day, then `ESMF_TimeIntervalGet(d = days, s = seconds)` would return `days = 1, seconds = 0`, whereas `ESMF_TimeIntervalGet(s = seconds)` would return `seconds = 86400`.

For `timeString`, converts `ESMF_TimeInterval`'s value into partial ISO 8601 format `PyYmMdDThHmMs[:n/d]S`. See [15] and [2]. See also method `ESMF_TimeIntervalPrint()`.
For timeStringISOFrac, converts ESMF_TimeInterval’s value into full ISO 8601 format PyYmMdDThH-mMs[f]. See [15] and [2]. See also method ESMF_TimeIntervalPrint().

The arguments are:

`timeinterval`  The object instance to query.

`calendarIn`  INPUT argument: pins a calendar interval to a specific calendar to allow conversion between relative units (yy, mm, d) and absolute units (d, h, m, s). Mutually exclusive with startTimeIn and endTimeIn since they contain a calendar. Alternate to, and mutually exclusive with, calkindflagIn below. Primarily for specifying a custom calendar kind.

- [yy] Integer year (32-bit).
- [yy_i8] Integer year (large, 64-bit).
- [mm] Integer month (32-bit).
- [mm_i8] Integer month (large, 64-bit).
- [d] Integer Julian day, or Modified Julian day (32-bit).
- [d_i8] Integer Julian day, or Modified Julian day (large, 64-bit).
- [h] Integer hour.
- [m] Integer minute.
- [s] Integer second (32-bit).
- [s_i8] Integer second (large, 64-bit).
- [ms] Integer millisecond.
- [us] Integer microsecond.
- [ns] Integer nanosecond.
- [d_r8] Double precision day.
- [h_r8] Double precision hour.
- [m_r8] Double precision minute.
- [s_r8] Double precision second.
- [ms_r8] Double precision millisecond.
- [us_r8] Double precision microsecond.
- [ns_r8] Double precision nanosecond.
- [sN] Integer numerator of fractional second (sN/sD).
- [sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit).
- [sD] Integer denominator of fractional second (sN/sD).
- [sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit).
- [startTime]  Starting time, if set, of an absolute calendar interval (yy, mm, and/or d).
- [calendar]  Associated Calendar, if any.
42.4.19  ESMF_TimeIntervalGet - Get a TimeInterval value

INTERFACE:

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the value of timeinterval in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally from integers.

Units are bound (normalized) to the next larger unit specified. For example, if a time interval is defined to be one day, then ESMF_TimeIntervalGet(d = days, s = seconds) would return days = 1, seconds = 0, whereas ESMF_TimeIntervalGet(s = seconds) would return seconds = 86400.

For timeString, converts ESMF_TimeInterval’s value into partial ISO 8601 format PyYmMdDThHmMs[:n/d]S. See [15] and [2]. See also method ESMF_TimeIntervalPrint().

For timeStringISOFrac, converts ESMF_TimeInterval’s value into full ISO 8601 format PyYmMdDThHmMs[.f]S. See [15] and [2]. See also method ESMF_TimeIntervalPrint().

The arguments are:

timeinterval The object instance to query.

calkindflagIn INPUT argument: Alternate to, and mutually exclusive with, calendarIn above. More convenient way of specifying a built-in calendar kind.

[yy] Integer year (32-bit).

[yy_i8] Integer year (large, 64-bit).

[mm] Integer month (32-bit).

[mm_i8] Integer month (large, 64-bit).

[d] Integer Julian day, or Modified Julian day (32-bit).
[d_i8]  Integer Julian day, or Modified Julian day (large, 64-bit).
[h]   Integer hour.
[m]   Integer minute.
[s]   Integer second (32-bit).
[s_i8] Integer second (large, 64-bit).
[ms]  Integer millisecond.
[us]  Integer microsecond.
[ns]  Integer nanosecond.
[d_r8] Double precision day.
[h_r8] Double precision hour.
[m_r8] Double precision minute.
[s_r8] Double precision second.
[ms_r8] Double precision millisecond.
[us_r8] Double precision microsecond.
[ns_r8] Double precision nanosecond.
[sN]  Integer numerator of fractional second (sN/sD).
[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[sD]  Integer denominator of fractional second (sN/sD).
[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit).
[startTime] Starting time, if set, of an absolute calendar interval (yy, mm, and/or d).
[calendar] Associated Calendar, if any.
[calkindflag] Associated CalKind_Flag, if any.
[timeString] Convert time interval value to format string PyYmMdDThHmMs[:n/d]S, where n/d is numerator/denominator of any fractional seconds and all other units are in ISO 8601 format. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[timeStringISOFrac] Convert time interval value to strict ISO 8601 format string PyYmMdDThHmMs[f], where f is decimal form of any fractional seconds. See [15] and [2]. See also method ESMF_TimeIntervalPrint().
[rc]   Return code; equals ESMF_SUCCESS if there are no errors.
42.4.20  ESMF_TimeIntervalNegAbsValue - Return the negative absolute value of a TimeInterval

INTERFACE:

    function ESMF_TimeIntervalNegAbsValue(timeinterval)

RETURN VALUE:

    type(ESMF_TimeInterval) :: ESMF_TimeIntervalNegAbsValue

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Returns the negative absolute value of timeinterval.

The argument is:

timeinterval  The object instance to take the negative absolute value of. Negative absolute value is returned as the value of the function.

42.4.21  ESMF_TimeIntervalPrint - Print TimeInterval information

INTERFACE:

    subroutine ESMF_TimeIntervalPrint(timeinterval, options, rc)

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval
    character (len=*) , intent(in), optional :: options
    integer, intent(out), optional :: rc
DESCRIPTION:

Prints out the contents of an ESMF_TimeInterval to stdout, in support of testing and debugging. The options control the type of information and level of detail.

The arguments are:

**timeinterval**  Time interval to be printed out.

**[options]**  Print options. If none specified, prints all timeinterval property values.

- "string" - prints timeinterval's value in ISO 8601 format for all units through seconds. For any non-zero fractional seconds, prints in integer rational fraction form n/d. Format is PyYmMdDThHmMs[:n/d]S, where [:n/d] is the integer numerator and denominator of the fractional seconds value, if present. See [15] and [2]. See also method `ESMF_TimeIntervalGet(..., timeString= , ...)`
- "string isofrac" - prints timeinterval’s value in strict ISO 8601 format for all units, including any fractional seconds part. Format is PyYmMdDThHmMs[f]S, where [f] represents fractional seconds in decimal form, if present. See [15] and [2]. See also method `ESMF_TimeIntervalGet(..., timeStringISOfrac= , ...)`

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

42.4.22  ESMF_TimeIntervalSet - Initialize or set a TimeInterval

INTERFACE:

```fortran
! Private name; call using ESMF_TimeIntervalSet()
subroutine ESMF_TimeIntervalSetDur(timeinterval, 
  &
  yy, yy_i8, &
  mm, mm_i8, &
  d, d_i8, &
  h, m, &
  s, s_i8, &
  ms, us, ns, &
  d_r8, h_r8, m_r8, s_r8, &
  ms_r8, us_r8, ns_r8, &
  sN, sN_i8, sD, sD_i8, rc)
```

ARGUMENTS:

```fortran
type(ESMF_TimeInterval), intent(inout) :: timeinterval
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer(ESMF_KIND_I4), intent(in), optional :: yy
integer(ESMF_KIND_I8), intent(in), optional :: yy_i8
integer(ESMF_KIND_I4), intent(in), optional :: mm
integer(ESMF_KIND_I8), intent(in), optional :: mm_i8
integer(ESMF_KIND_I4), intent(in), optional :: d
integer(ESMF_KIND_I8), intent(in), optional :: d_i8
```

969
integer(ESMF_KIND_I4), intent(in), optional :: h
integer(ESMF_KIND_I4), intent(in), optional :: m
integer(ESMF_KIND_I4), intent(in), optional :: s
integer(ESMF_KIND_I8), intent(in), optional :: s_i8
integer(ESMF_KIND_I4), intent(in), optional :: ms
integer(ESMF_KIND_I4), intent(in), optional :: us

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets the value of the ESMF_TimeInterval in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally to integers.

Ranges are limited only by machine word size. Numeric defaults are 0, except for sD, which is 1.

The arguments are:

- **timeinterval** The object instance to initialize.
- **startTime** Starting time of an absolute calendar interval (yy, mm, and/or d); pins a calendar interval to a specific point in time. If not set, and calendar also not set, calendar interval "floats" across all calendars and times.
- **[yy]** Integer year (32-bit). Default = 0.
- **[yy_i8]** Integer year (large, 64-bit). Default = 0.
- **[mm]** Integer month (32-bit). Default = 0.
[mm_i8] Integer month (large, 64-bit). Default = 0.
[d] Integer Julian day, or Modified Julian day (32-bit). Default = 0.
[d_i8] Integer Julian day, or Modified Julian day (large, 64-bit). Default = 0.
[h] Integer hour. Default = 0.
[m] Integer minute. Default = 0.
[s] Integer second (32-bit). Default = 0.
[s_i8] Integer second (large, 64-bit). Default = 0.
[ms] Integer millisecond. Default = 0.
[us] Integer microsecond. Default = 0.
[ns] Integer nanosecond. Default = 0.
[d_r8] Double precision day. Default = 0.0.
[h_r8] Double precision hour. Default = 0.0.
[m_r8] Double precision minute. Default = 0.0.
[s_r8] Double precision second. Default = 0.0.
[ms_r8] Double precision millisecond. Default = 0.0.
[us_r8] Double precision microsecond. Default = 0.0.
[ns_r8] Double precision nanosecond. Default = 0.0.
[sN] Integer numerator of fractional second (sN/sD). Default = 0.
[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8) (large, 64-bit). Default = 0.
[sD] Integer denominator of fractional second (sN/sD). Default = 1.
[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8) (large, 64-bit). Default = 1.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

42.4.24 ESMF_TimeIntervalSet - Initialize or set a TimeInterval

INTERFACE:

```fortran
  ! Private name; call using ESMF_TimeIntervalSet() subroutine
  subroutine ESMF_TimeIntervalSetDurCal(timeinterval, calendar, &
    yy, yy_i8, &
    mm, mm_i8, &
    d, d_i8, &
    h, m, &
    s, s_i8, &
    ms, us, ns, &
```
ARGUMENTS:

- type(ESMF_TimeInterval), intent(inout) :: timeinterval
- type(ESMF_Calendar), intent(in) :: calendar
- integer(ESMF_KIND_I4), intent(in), optional :: yy
- integer(ESMF_KIND_I8), intent(in), optional :: yy_i8
- integer(ESMF_KIND_I4), intent(in), optional :: mm
- integer(ESMF_KIND_I8), intent(in), optional :: mm_i8
- integer(ESMF_KIND_I4), intent(in), optional :: d
- integer(ESMF_KIND_I8), intent(in), optional :: d_i8
- integer(ESMF_KIND_I4), intent(in), optional :: h
- integer(ESMF_KIND_I8), intent(in), optional :: h_r8
- integer(ESMF_KIND_I4), intent(in), optional :: m
- integer(ESMF_KIND_I8), intent(in), optional :: m_r8
- integer(ESMF_KIND_I4), intent(in), optional :: s
- integer(ESMF_KIND_I8), intent(in), optional :: s_r8
- integer, intent(out), optional :: rc
- real(ESMF_KIND_R8), intent(in), optional :: d_r8
- real(ESMF_KIND_R8), intent(in), optional :: h_r8
- real(ESMF_KIND_R8), intent(in), optional :: m_r8
- real(ESMF_KIND_R8), intent(in), optional :: s_r8
- real(ESMF_KIND_R8), intent(in), optional :: ms_r8
- real(ESMF_KIND_R8), intent(in), optional :: us_r8
- real(ESMF_KIND_R8), intent(in), optional :: ns_r8
- integer(ESMF_KIND_I4), intent(in), optional :: sN
- integer(ESMF_KIND_I8), intent(in), optional :: sN_i8
- integer(ESMF_KIND_I4), intent(in), optional :: sD
- integer(ESMF_KIND_I8), intent(in), optional :: sD_i8

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets the value of the ESMF_TimeInterval in units specified by the user via Fortran optional arguments. The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally to integers.

Ranges are limited only by machine word size. Numeric defaults are 0, except for sD, which is 1.

The arguments are:

**timeinterval**  The object instance to initialize.
calendar Calendar used to give better definition to calendar interval (yy, mm, and/or d) for arithmetic, comparison, and conversion operations. Allows calendar interval to "float" across all times on a specific calendar. Default = NULL; if startTime also not specified, calendar interval "floats" across all calendars and times. Mutually exclusive with startTime since it contains a calendar. Alternate to, and mutually exclusive with, calkindflag below. Primarily for specifying a custom calendar kind.

[yy] Integer year (32-bit). Default = 0.
[yy_i8] Integer year (large, 64-bit). Default = 0.
[mm] Integer month (32-bit). Default = 0.
[mm_i8] Integer month (large, 64-bit). Default = 0.
[d] Integer Julian day, or Modified Julian day (32-bit). Default = 0.
[d_i8] Integer Julian day, or Modified Julian day (large, 64-bit). Default = 0.
[h] Integer hour. Default = 0.
[m] Integer minute. Default = 0.
[s] Integer second (32-bit). Default = 0.
[s_i8] Integer second (large, 64-bit). Default = 0.
[ms] Integer millisecond. Default = 0.
[us] Integer microsecond. Default = 0.
[ns] Integer nanosecond. Default = 0.
[d_r8] Double precision day. Default = 0.0.
[h_r8] Double precision hour. Default = 0.0.
[m_r8] Double precision minute. Default = 0.0.
[s_r8] Double precision second. Default = 0.0.
[ms_r8] Double precision millisecond. Default = 0.0.
[us_r8] Double precision microsecond. Default = 0.0.
[ns_r8] Double precision nanosecond. Default = 0.0.
[sN] Integer numerator of fractional second (sN/sD). Default = 0.
[sN_i8] Integer numerator of fractional second (sN_i8/sD_i8). (large, 64-bit). Default = 0.
[sD] Integer denominator of fractional second (sN/sD). Default = 1.
[sD_i8] Integer denominator of fractional second (sN_i8/sD_i8). (large, 64-bit). Default = 1.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.
42.4.25 ESMF_TimeIntervalSet - Initialize or set a TimeInterval

INTERFACE:

! Private name; call using ESMF_TimeIntervalSet()
subroutine ESMF_TimeIntervalSetDurCalTyp(timeinterval, calkindflag, &
 &
 yy, yy_i8, &
 mm, mm_i8, &
 d, d_i8, &
 h, m, &
 s, s_i8, &
 ms, us, ns, &
 d_r8, h_r8, m_r8, s_r8, &
 ms_r8, us_r8, ns_r8, &
 sN, sN_i8, sD, sD_i8, &
 rc)

ARGUMENTS:

  type(ESMF_TimeInterval), intent(inout) :: timeinterval
  type(ESMF_CalKind_Flag), intent(in) :: calkindflag
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer(ESMF_KIND_I4), intent(in), optional :: yy
  integer(ESMF_KIND_I8), intent(in), optional :: yy_i8
  integer(ESMF_KIND_I4), intent(in), optional :: mm
  integer(ESMF_KIND_I8), intent(in), optional :: mm_i8
  integer(ESMF_KIND_I4), intent(in), optional :: d
  integer(ESMF_KIND_I8), intent(in), optional :: d_i8
  integer(ESMF_KIND_I4), intent(in), optional :: h
  integer(ESMF_KIND_I4), intent(in), optional :: m
  integer(ESMF_KIND_I4), intent(in), optional :: s
  integer(ESMF_KIND_I8), intent(in), optional :: s_i8
  integer(ESMF_KIND_I4), intent(in), optional :: ms
  integer(ESMF_KIND_I4), intent(in), optional :: us
  integer(ESMF_KIND_I4), intent(in), optional :: ns
  real(ESMF_KIND_R8), intent(in), optional :: d_r8
  real(ESMF_KIND_R8), intent(in), optional :: h_r8
  real(ESMF_KIND_R8), intent(in), optional :: m_r8
  real(ESMF_KIND_R8), intent(in), optional :: s_r8
  real(ESMF_KIND_R8), intent(in), optional :: ms_r8
  real(ESMF_KIND_R8), intent(in), optional :: us_r8
  real(ESMF_KIND_R8), intent(in), optional :: ns_r8
  integer(ESMF_KIND_I4), intent(in), optional :: sN
  integer(ESMF_KIND_I8), intent(in), optional :: sN_i8
  integer(ESMF_KIND_I4), intent(in), optional :: sD
  integer(ESMF_KIND_I8), intent(in), optional :: sD_i8
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Sets the value of the `ESMF_TimeInterval` in units specified by the user via Fortran optional arguments.

The ESMF Time Manager represents and manipulates time internally with integers to maintain precision. Hence, user-specified floating point values are converted internally to integers.

Ranges are limited only by machine word size. Numeric defaults are 0, except for `sD`, which is 1.

The arguments are:

- `timeinterval` The object instance to initialize.
- `calendarFlag` Alternate to, and mutually exclusive with, calendar above. More convenient way of specifying a built-in calendar kind.

- `[yy]` Integer year (32-bit). Default = 0.
- `[yy_i8]` Integer year (large, 64-bit). Default = 0.
- `[mm]` Integer month (32-bit). Default = 0.
- `[mm_i8]` Integer month (large, 64-bit). Default = 0.
- `[d]` Integer Julian day, or Modified Julian day (32-bit). Default = 0.
- `[d_i8]` Integer Julian day, or Modified Julian day (large, 64-bit). Default = 0.
- `[h]` Integer hour. Default = 0.
- `[m]` Integer minute. Default = 0.
- `[s]` Integer second (32-bit). Default = 0.
- `[s_i8]` Integer second (large, 64-bit). Default = 0.
- `[ms]` Integer millisecond. Default = 0.
- `[us]` Integer microsecond. Default = 0.
- `[ns]` Integer nanosecond. Default = 0.
- `[d_r8]` Double precision day. Default = 0.0.
- `[h_r8]` Double precision hour. Default = 0.0.
- `[m_r8]` Double precision minute. Default = 0.0.
- `[s_r8]` Double precision second. Default = 0.0.
- `[ms_r8]` Double precision millisecond. Default = 0.0.
- `[us_r8]` Double precision microsecond. Default = 0.0.
- `[ns_r8]` Double precision nanoseconds. Default = 0.0.
- `[sN]` Integer numerator of fractional second (`sN/sD`). Default = 0.
- `[sN_i8]` Integer numerator of fractional second (`sN_i8/sD_i8`) (large, 64-bit). Default = 0.
- `[sD]` Integer denominator of fractional second (`sN/sD`). Default = 1.
- `[sD_i8]` Integer denominator of fractional second (`sN_i8/sD_i8`) (large, 64-bit). Default = 1.
- `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.
42.4.26 ESMF_TimeIntervalValidate - Validate a TimeInterval

INTERFACE:

    subroutine ESMF_TimeIntervalValidate(timeinterval, rc)

ARGUMENTS:

    type(ESMF_TimeInterval), intent(in) :: timeinterval
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Checks whether a timeinterval is valid. If fractional value, denominator must be non-zero.

The arguments are:

    timeinterval ESMF_TimeInterval to be validated.

    [rc] Return code; equals ESMF_SUCCESS if there are no errors.
43 Clock Class

43.1 Description

The Clock class advances model time and tracks its associated date on a specified Calendar. It stores start time, stop time, current time, previous time, and a time step. It can also store a reference time, typically the time instant at which a simulation originally began. For a restart run, the reference time can be different than the start time, when the application execution resumes.

A user can call the ESMF_ClockSet method and reset the time step as desired.

A Clock also stores a list of Alarms, which can be set to flag events that occur at a specified time instant or at a specified time interval. See Section 44.1 for details on how to use Alarms.

There are methods for setting and getting the Times and Alarms associated with a Clock. Methods are defined for advancing the Clock’s current time, checking if the stop time has been reached, reversing direction, and synchronizing with a real clock.

43.2 Constants

43.2.1 ESMF_DIRECTION

DESCRIPTION:

Specifies the time-stepping direction of a clock. Use with "direction" argument to methods ESMF_ClockSet() and ESMF_ClockGet(). Cannot be used with method ESMF_ClockCreate(), since it only initializes a clock in the default forward mode; a clock must be advanced (timestepped) at least once before reversing direction via ESMF_ClockSet(). This also holds true for negative timestep clocks which are initialized (created) with stopTime < startTime, since "forward" means timestepping from startTime towards stopTime (see ESMF_DIRECTION_FORWARD below).

"Forward" and "reverse" directions are distinct from positive and negative timesteps. "Forward" means timestepping in the direction established at ESMF_ClockCreate(), from startTime towards stopTime, regardless of the timestep sign. "Reverse" means timestepping in the opposite direction, back towards the clock’s startTime, regardless of the timestep sign.

Clocks and alarms run in reverse in such a way that the state of a clock and its alarms after each time step is precisely replicated as it was in forward time-stepping mode. All methods which query clock and alarm state will return the same result for a given timeStep, regardless of the direction of arrival.

The type of this flag is:

type (ESMF_Direction_Flag)

The valid values are:

ESMF_DIRECTION_FORWARD Upon calling ESMF_ClockAdvance(), the clock will timestep from its start-Time toward its stopTime. This is the default direction. A user can use either ESMF_ClockIsStopTime() or ESMF_ClockIsDone() methods to determine when stopTime is reached. This forward behavior also holds for negative timestep clocks which are initialized (created) with stopTime < startTime.

ESMF_DIRECTION_REVERSE Upon calling ESMF_ClockAdvance(), the clock will timestep backwards toward its startTime. Use method ESMF_ClockIsDone() to determine when startTime is reached. This reverse
behavior also holds for negative timestep clocks which are initialized (created) with stopTime < startTime.

43.3 Use and Examples

The following is a typical sequence for using a Clock in a geophysical model.

At initialize:

- Set a Calendar.
- Set start time, stop time and time step as Times and Time Intervals.
- Create and Initialize a Clock using the start time, stop time and time step.
- Define Times and Time Intervals associated with special events, and use these to set Alarms.

At run:

- Advance the Clock, checking for ringing alarms as needed.
- Check if it is time to stop.

At finalize:

- Since Clocks and Alarms are deep classes, they need to be explicitly destroyed at finalization. Times and TimeIntervals are lightweight classes, so they don’t need explicit destruction.

The following code example illustrates Clock usage.

```plaintext
! PROGRAM: ESMF_ClockEx - Clock initialization and time-stepping
!
! DESCRIPTION:
!
! This program shows an example of how to create, initialize, advance, and examine a basic clock
!-------------------------------------------------- ---------------------------
#include "ESMF.h"

! instantiate a clock
type(ESMF_Clock) :: clock

! instantiate time_step, start and stop times
type(ESMF_TimeInterval) :: timeStep
type(ESMF_Time) :: startTime
type(ESMF_Time) :: stopTime

! local variables for Get methods
```
43.3.1 Clock creation

This example shows how to create and initialize an ESMF_Clock.

! initialize time interval to 2 days, 4 hours (6 timesteps in 13 days)
call ESMF_TimeIntervalSet(timeStep, d=2, h=4, rc=rc)

! initialize start time to 4/1/2003 2:24:00 (1/10 of a day)
call ESMF_TimeSet(startTime, yy=2003, mm=4, dd=1, h=2, m=24, rc=rc)

! initialize stop time to 4/14/2003 2:24:00 (1/10 of a day)
call ESMF_TimeSet(stopTime, yy=2003, mm=4, dd=14, h=2, m=24, rc=rc)

! initialize the clock with the above values
clock = ESMF_ClockCreate(timeStep, startTime, stopTime=stopTime, &
  name="Clock 1", rc=rc)

43.3.2 Clock advance

This example shows how to time-step an ESMF_Clock.

! time step clock from start time to stop time
do while (.not.ESMF_ClockIsStopTime(clock, rc=rc))

call ESMF_ClockPrint(clock, options="currTime string", rc=rc)

call ESMF_ClockAdvance(clock, rc=rc)
end do
43.3.3 Clock examination

This example shows how to examine an ESMF_Clock.

! get the clock’s final current time
call ESMF_ClockGet(clock, currTime=currTime, rc=rc)

call ESMF_TimeGet(currTime, yy=YY, mm=MM, dd=DD, h=H, m=M, s=S, rc=rc)
print *, "The clock’s final current time is ", YY, "/", MM, "/", DD, &
" ", H, ":", M, ":", S

! get the number of times the clock was advanced
call ESMF_ClockGet(clock, advanceCount=advanceCount, rc=rc)
print *, "The clock was advanced ", advanceCount, " times."

43.3.4 Clock reversal

This example shows how to time-step an ESMF_Clock in reverse mode.

call ESMF_ClockSet(clock, direction=ESMF_DIRECTION_REVERSE, rc=rc)

! time step clock in reverse from stop time back to start time;
! note use of ESMF_ClockIsDone() rather than ESMF_ClockIsStopTime()
do while (.not.ESMF_ClockIsDone(clock, rc=rc))

call ESMF_ClockPrint(clock, options="currTime string", rc=rc)

call ESMF_ClockAdvance(clock, rc=rc)

end do

43.3.5 Clock destruction

This example shows how to destroy an ESMF_Clock.

! destroy clock
call ESMF_ClockDestroy(clock, rc=rc)

! finalize ESMF framework
call ESMF_Finalize(rc=rc)
43.4 Restrictions and Future Work

1. Alarm list allocation factor The alarm list within a clock is dynamically allocated automatically, 200 alarm references at a time. This constant is defined in both Fortran and C++ with a #define for ease of modification.

2. Clock variable timesteps in reverse

In order for a clock with variable timesteps to be run in ESMF_DIRECTION_REVERSE, the user must supply those timesteps to ESMF_ClockAdvance(). Essentially, the user must save the timesteps while in forward mode. In a future release, the Time Manager will assume this responsibility by saving the clock state (including the timeStep) at every timestep while in forward mode.

43.5 Class API

43.5.1 ESMF_ClockAssignment(=) - Assign a Clock to another Clock

INTERFACE:

    interface assignment(=)
    clock1 = clock2

ARGUMENTS:

    type(ESMF_Clock) :: clock1
    type(ESMF_Clock) :: clock2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign clock1 as an alias to the same ESMF_Clock object in memory as clock2. If clock2 is invalid, then clock1 will be equally invalid after the assignment.

The arguments are:

clock1 The ESMF_Clock object on the left hand side of the assignment.

clock2 The ESMF_Clock object on the right hand side of the assignment.
43.5.2  ESMF_ClockOperator(==) - Test if Clock 1 is equal to Clock 2

INTERFACE:

interface operator(==)
  if (clock1 == clock2) then ... endif
  OR
  result = (clock1 == clock2)
endif

RETURN VALUE:

logical :: result

ARGUMENTS:

  type(ESMF_Clock), intent(in) :: clock1
  type(ESMF_Clock), intent(in) :: clock2

DESCRIPTION:

Overloads the (==) operator for the ESMF_Clock class. Compare two clocks for equality: return .true. if equal, .false. otherwise. Comparison is based on IDs, which are distinct for newly created clocks and identical for clocks created as copies.

If either side of the equality test is not in the ESMF_INIT_CREATED status an error will be logged. However, this does not affect the return value, which is .true. when both sides are in the same status, and .false. otherwise.

The arguments are:

clock1  The ESMF_Clock object on the left hand side of the equality operation.
clock2  The ESMF_Clock object on the right hand side of the equality operation.

43.5.3  ESMF_ClockOperator(/=) - Test if Clock 1 is not equal to Clock 2

INTERFACE:

interface operator(/=)
  if (clock1 /= clock2) then ... endif
  OR
  result = (clock1 /= clock2)
endif

RETURN VALUE:

logical :: result

ARGUMENTS:
type(ESMF_Clock), intent(in) :: clock1
type(ESMF_Clock), intent(in) :: clock2

DESCRIPTION:

Overloads the (=) operator for the ESMF_Clock class. Compare two clocks for inequality; return .true. if not equal, .false. otherwise. Comparison is based on IDs, which are distinct for newly created clocks and identical for clocks created as copies.

If either side of the equality test is not in the ESMF_INIT_CREATED status an error will be logged. However, this does not affect the return value, which is .true. when both sides are not in the same status, and .false. otherwise.

The arguments are:

clock1 The ESMF_Clock object on the left hand side of the non-equality operation.

clock2 The ESMF_Clock object on the right hand side of the non-equality operation.

43.5.4 ESMF_ClockAdvance - Advance a Clock’s current time by one time step

INTERFACE:

subroutine ESMF_ClockAdvance(clock, 
   &
   timeStep, ringingAlarmList, ringingAlarmCount, rc)

ARGUMENTS:

   type(ESMF_Clock), intent(inout) :: clock
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_TimeInterval), intent(in), optional :: timeStep
   type(ESMF_Alarm), intent(out), optional :: ringingAlarmList(:)
   integer, intent(out), optional :: ringingAlarmCount
   integer, intent(out), optional :: rc

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Advances the clock's current time by one time step: either the clock's, or the passed-in timeStep (see below). When the clock is in ESMF DIRECTION_FORWARD (default), this method adds the timeStep to the clock's current time. In ESMF DIRECTION_REVERSE, timeStep is subtracted from the current time. In either case, timeStep can be positive or negative. See the “direction” argument in method ESMF_ClockSet().
ESMF_ClockAdvance() optionally returns a list and number of ringing ESMF_Alarms. See also method ESMF_ClockGetRingingAlarms().

The arguments are:

clock  The object instance to advance.

[timeStep]  Time step is performed with given timeStep, instead of the ESMF_Clock's. Does not replace the ESMF_Clock's timeStep; use ESMF_ClockSet(clock, timeStep, ...) for this purpose. Supports applications with variable time steps. timeStep can be positive or negative.

[ringingAlarmList]  Returns the array of alarms that are ringing after the time step.

[ringingAlarmCount]  The number of alarms ringing after the time step.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

### 43.5.5 ESMF_ClockCreate - Create a new ESMF Clock

**INTERFACE:**

```plaintext
! Private name; call using ESMF_ClockCreate()
function ESMF_ClockCreateNew(timeStep, startTime, &
   stopTime, runDuration, runTimeStepCount, refTime, name, rc)
```

**RETURN VALUE:**

```
type(ESMF_Clock) :: ESMF_ClockCreateNew
```

**ARGUMENTS:**

```
type(ESMF_TimeInterval), intent(in) :: timeStep

type(ESMF_Time), intent(in) :: startTime

-- The following arguments require argument keyword syntax (e.g. rc=rc). --

type(ESMF_Time), intent(in), optional :: stopTime

type(ESMF_TimeInterval), intent(in), optional :: runDuration

integer, intent(in), optional :: runTimeStepCount

character (len=*) , intent(in), optional :: name

integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Creates and sets the initial values in a new ESMF_Clock.

The arguments are:

timestep  The ESMF_Clock’s time step interval, which can be positive or negative.

startTime  The ESMF_Clock’s starting time. Can be less than or greater than stopTime, depending on a positive or negative timeStep, respectively, and whether a stopTime is specified; see below.

[stopTime]  The ESMF_Clock’s stopping time. Can be greater than or less than the startTime, depending on a positive or negative timeStep, respectively. If neither stopTime, runDuration, nor runTimeStepCount is specified, clock runs "forever"; user must use other means to know when to stop (e.g. ESMF_Alarm or ESMF_ClockGet(clock, currTime)). Mutually exclusive with runDuration and runTimeStepCount.

[runDuration]  Alternative way to specify ESMF_Clock’s stopping time; stopTime = startTime + runDuration. Can be positive or negative, consistent with the timeStep’s sign. Mutually exclusive with stopTime and runTimeStepCount.

[runTimeStepCount]  Alternative way to specify ESMF_Clock’s stopping time; stopTime = startTime + (runTimeStepCount * timeStep). stopTime can be before startTime if timeStep is negative. Mutually exclusive with stopTime and runDuration.

[refTime]  The ESMF_Clock’s reference time. Provides reference point for simulation time (see currSimTime in ESMF_ClockGet() below).

[name]  The name for the newly created clock. If not specified, a default unique name will be generated: "ClockNNN" where NNN is a unique sequence number from 001 to 999.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.6 ESMF_ClockCreate - Create a copy of an existing ESMF Clock

INTERFACE:

    ! Private name; call using ESMF_ClockCreate()
    function ESMF_ClockCreateCopy(clock, rc)

RETURN VALUE:

    type(ESMF_Clock) :: ESMF_ClockCreateCopy

ARGUMENTS:

    type(ESMF_Clock), intent(in) :: clock
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Creates a deep copy of a given ESMF_Clock, but does not copy its list of ESMF_Alarms (pointers), since an ESMF_Alarm can only be associated with one ESMF_Clock. Hence, the returned ESMF_Clock copy has no associated ESMF_Alarms, the same as with a newly created ESMF_Clock. If desired, new ESMF_Alarms must be created and associated with this copied ESMF_Clock via ESMF_AlarmCreate(), or existing ESMF_Alarms must be re-associated with this copied ESMF_Clock via ESMF_AlarmSet(...clock=...).

The arguments are:

clock The ESMF_Clock to copy.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

43.5.7 ESMF_ClockDestroy - Release resources associated with a Clock

INTERFACE:

    subroutine ESMF_ClockDestroy(clock, rc)

ARGUMENTS:

    type(ESMF_Clock), intent(inout) :: clock
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Releases resources associated with this ESMF_Clock. This releases the list of associated ESMF_Alarms (pointers), but not the ESMF_Alarms themselves; the user must explicitly call ESMF_AlarmDestroy() on each ESMF_Alarm to release its resources. ESMF_ClockDestroy() and corresponding ESMF_AlarmDestroy()s can be called in either order.

If ESMF_ClockDestroy() is called before ESMF_AlarmDestroy(), any ESMF_Alarms that were in the ESMF_Clock's list will no longer be associated with any ESMF_Clock. If desired, these "orphaned" ESMF_Alarms can be associated with a different ESMF_Clock via a call to ESMF_AlarmSet(...clock=...).

The arguments are:
clock  Release resources associated with this ESMF_Clock and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.8 ESMF_ClockGet - Get a Clock’s properties

INTERFACE:

subroutine ESMF_ClockGet(clock, &
  timeStep,startTime, stopTime, &
  runDuration, runTimeStepCount, refTime, currTime, prevTime, &
  currSimTime, prevSimTime, calendar, calkindflag, timeZone, &
  advanceCount, alarmCount, direction, name, rc)

ARGUMENTS:

type(ESMF_Clock), intent(in) :: clock
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_TimeInterval), intent(out), optional :: timeStep
type(ESMF_Time), intent(out), optional :: startTime
type(ESMF_Time), intent(out), optional :: stopTime
type(ESMF_TimeInterval), intent(out), optional :: runDuration
real(ESMF_KIND_R8), intent(out), optional :: runTimeStepCount
type(ESMF_Time), intent(out), optional :: refTime
type(ESMF_Time), intent(out), optional :: currTime
type(ESMF_Time), intent(out), optional :: prevTime
type(ESMF_TimeInterval), intent(out), optional :: currSimTime
type(ESMF_TimeInterval), intent(out), optional :: prevSimTime
type(ESMF_Calendar), intent(out), optional :: calendar
type(ESMF_CalKind_Flag), intent(out), optional :: calkindflag
integer, intent(out), optional :: timeZone
integer(ESMF_KIND_I8), intent(out), optional :: advanceCount
integer, intent(out), optional :: alarmCount
type(ESMF_Direction_Flag), intent(out), optional :: direction
character (len=*), intent(out), optional :: name
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets one or more of the properties of an ESMF_Clock.

The arguments are:
clock The object instance to query.

[timeStep] The ESMF_Clock’s time step interval.
[startTime] The ESMF_Clock’s starting time.
[stopTime] The ESMF_Clock’s stopping time.
[runDuration] Alternative way to get ESMF_Clock’s stopping time; runDuration = stopTime - startTime.
[runTimeStepCount] Alternative way to get ESMF_Clock’s stopping time; runTimeStepCount = (stopTime - startTime) / timeStep.
[refTime] The ESMF_Clock’s reference time.
[currTime] The ESMF_Clock’s current time.
[prevTime] The ESMF_Clock’s previous time. Equals currTime at the previous time step.
[currSimTime] The current simulation time (currTime - refTime).
[prevSimTime] The previous simulation time. Equals currSimTime at the previous time step.
[calendar] The Calendar on which all the Clock’s times are defined.
[calkindflag] The CalKind_Flag on which all the Clock’s times are defined.
[timeZone] The timezone within which all the Clock’s times are defined.
[advanceCount] The number of times the ESMF_Clock has been advanced. Increments in ESMF_DIRECTION_FORWARD and decrements in ESMF_DIRECTION_REVERSE; see "direction" argument below and in ESMF_ClockSet().
[alarmCount] The number of ESMF_Alarms in the ESMF_Clock’s ESMF_Alarm list.
[direction] The ESMF_Clock’s time stepping direction. See also ESMF_ClockIsReverse(), an alternative for convenient use in "if" and "do while" constructs.
[name] The name of this clock.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

43.5.9 ESMF_ClockGetAlarm - Get an Alarm in a Clock’s Alarm list

INTERFACE:

    subroutine ESMF_ClockGetAlarm(clock, alarmname, alarm, &
rc)

ARGUMENTS:

    type(ESMF_Clock), intent(in) :: clock
    character (len=*) , intent(in) :: alarmname
    type(ESMF_Alarm), intent(out) :: alarm

-- The following arguments require argument keyword syntax (e.g. rc=rc).  --
   integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the alarm whose name is the value of alarmname in the clock’s ESMF_Alarm list.

The arguments are:

clock  The object instance to get the ESMF_Alarm from.
alarmname  The name of the desired ESMF_Alarm.
alarm  The desired alarm.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.10  ESMF_ClockGetAlarmList - Get a list of Alarms from a Clock

INTERFACE:

subroutine ESMF_ClockGetAlarmList(clock, alarmlistflag, &
    timeStep, alarmList, alarmCount, rc)

ARGUMENTS:

type(ESMF_Clock), intent(in) :: clock
type(ESMF_AlarmList_Flag), intent(in) :: alarmlistflag
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_TimeInterval), intent(in), optional :: timeStep
type(ESMF_Alarm), intent(out), optional :: alarmList(:)
imTEGER, intent(out), optional :: alarmCount
INTEGER, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the clock’s list of alarms and/or number of alarms.

The arguments are:
**clock**  The object instance from which to get an `ESMF_Alarm` list and/or count of `ESMF_Alarms`.

**alarmlistflag**  The kind of list to get:

- `ESMF_ALARMLIST_ALL`: Returns the `ESMF_Clock`’s entire list of alarms.
- `ESMF_ALARMLIST_NEXTRINGING`: Return only those alarms that will ring upon the next clock time step. Can optionally specify argument `timeStep` (see below) to use instead of the clock’s. See also method `ESMF_AlarmWillRingNext()` for checking a single alarm.
- `ESMF_ALARMLIST_PREVRINGING`: Return only those alarms that were ringing on the previous `ESMF_Clock` time step. See also method `ESMF_AlarmWasPrevRinging()` for checking a single alarm.
- `ESMF_ALARMLIST_RINGING`: Returns only those `clock` alarms that are currently ringing. See also method `ESMF_ClockAdvance()` for getting the list of ringing alarms subsequent to a time step. See also method `ESMF_AlarmIsRinging()` for checking a single alarm.

**[timeStep]** Optional time step to be used instead of the clock’s. Only used with `ESMF_ALARMLIST_NEXTRINGING` alarmlistflag (see above); ignored if specified with other alarmlistflags.

**[alarmList]** The array of returned alarms. If given, the array must be large enough to hold the number of alarms of the specified alarmlistflag in the specified clock.

**[alarmCount]** If specified, returns the number of `ESMF_Alarms` of the specified alarmlistflag in the specified clock.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

### 43.5.11 ESMF_ClockGetNextTime - Calculate a Clock’s next time

**INTERFACE:**

```fortran
subroutine ESMF_ClockGetNextTime(clock, nextTime, &
                                  timeStep, rc)
```

**ARGUMENTS:**

```fortran
type(ESMF_Clock), intent(in) :: clock
type(ESMF_Time), intent(out) :: nextTime
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_TimeInterval), intent(in), optional :: timeStep
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Calculates what the next time of the clock will be, based on the clock’s current time step or an optionally passed-in timeStep.

The arguments are:

**clock**  The object instance for which to get the next time.

**nextTime**  The resulting ESMF_Clock’s next time.

**[timeStep]**  The time step interval to use instead of the clock’s.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

43.5.12  ESMF_ClockIsDone - Based on its direction, test if the Clock has reached or exceeded its stop time or start time

INTERFACE:

```fortran
function ESMF_ClockIsDone(clock, rc)
```

RETURN VALUE:

```fortran
logical :: ESMF_ClockIsDone
```

ARGUMENTS:

```fortran
type(ESMF_Clock), intent(in) :: clock
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns true if currentTime is greater than or equal to stopTime in ESMF_DIRECTION_FORWARD, or if currentTime is less than or equal to startTime in ESMF_DIRECTION_REVERSE. It returns false otherwise.

The arguments are:

**clock**  The object instance to check.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.
43.5.13  ESMF_ClockIsReverse - Test if the Clock is in reverse mode

INTERFACE:

function ESMF_ClockIsReverse(clock, rc)

RETURN VALUE:

logical :: ESMF_ClockIsReverse

ARGUMENTS:

type(ESMF_Clock), intent(in) :: clock
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Returns true if clock is in ESMF_DIRECTION_REVERSE, and false if in ESMF_DIRECTION_FORWARD. Allows convenient use in "if" and "do while" constructs. Alternative to ESMF_ClockGet(...direction=...).

The arguments are:

clock  The object instance to check.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.14  ESMF_ClockIsStopTime - Test if the Clock has reached or exceeded its stop time

INTERFACE:

function ESMF_ClockIsStopTime(clock, rc)

RETURN VALUE:

logical :: ESMF_ClockIsStopTime

ARGUMENTS:
Returns true if the \texttt{clock} has reached or exceeded its stop time, and false otherwise.

The arguments are:

\texttt{clock}  The object instance to check.

\texttt{[rc]}  Return code; equals \texttt{ESMF\_SUCCESS} if there are no errors.
clock  The object instance to check.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.16 ESMF_ClockPrint - Print Clock information

INTERFACE:

    subroutine ESMF_ClockPrint(clock, options, rc)

ARGUMENTS:

type(ESMF_Clock), intent(in) :: clock
character (len=*), intent(in), optional :: options
integer, intent(out), optional :: rc

DESCRIPTION:

Prints out an ESMF_Clock's properties to stdout, in support of testing and debugging. The options control the type of information and level of detail.

The arguments are:

clock  ESMF_Clock to be printed out.

[options]  Print options. If none specified, prints all clock property values.
    "advanceCount" - print the number of times the clock has been advanced.
    "alarmCount" - print the number of alarms in the clock's list.
    "alarmList" - print the clock's alarm list.
    "currTime" - print the current clock time.
    "direction" - print the clock's timestep direction.
    "name" - print the clock's name.
    "prevTime" - print the previous clock time.
    "refTime" - print the clock's reference time.
    "startTime" - print the clock's start time.
    "stopTime" - print the clock's stop time.
    "timeStep" - print the clock's time step.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.17 ESMF_ClockSet - Set one or more properties of a Clock

INTERFACE:
subroutine ESMF_ClockSet(clock, &
  timeStep, startTime, stopTime, &
  runDuration, runTimeStepCount, refTime, currTime, advanceCount, &
  direction, name, rc)

ARGUMENTS:

  type(ESMF_Clock), intent(inout) :: clock  
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_TimeInterval), intent(in), optional :: timeStep
  type(ESMF_Time), intent(in), optional :: startTime
  type(ESMF_Time), intent(in), optional :: stopTime
  type(ESMF_TimeInterval), intent(in), optional :: runDuration
  integer, intent(in), optional :: runTimeStepCount
  type(ESMF_Time), intent(in), optional :: refTime
  type(ESMF_Time), intent(in), optional :: currTime
  integer(ESMF_KIND_I8), intent(in), optional :: advanceCount
  type(ESMF_Direction_Flag), intent(in), optional :: direction
  character (len=*) , intent(in), optional :: name
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets/resets one or more of the properties of an ESMF_Clock that was previously initialized via ESMF_ClockCreate().

The arguments are:

clock  The object instance to set.

timeStep  The ESMF_Clock’s time step interval, which can be positive or negative. This is used to change a clock’s timestep property for those applications that need variable timesteps. See ESMF_ClockAdvance() below for specifying variable timesteps that are NOT saved as the clock’s internal time step property. See "direction" argument below for behavior with ESMF_DIRECTION_REVERSE direction.

startTime  The ESMF_Clock’s starting time. Can be less than or greater than stopTime, depending on a positive or negative timeStep, respectively, and whether a stopTime is specified; see below.

stopTime  The ESMF_Clock’s stopping time. Can be greater than or less than the startTime, depending on a positive or negative timeStep, respectively. If neither stopTime, runDuration, nor runTimeStepCount is specified, clock runs "forever": user must use other means to know when to stop (e.g. ESMF_Alarm or ESMF_ClockGet(clock, currTime)). Mutually exclusive with runDuration and runTimeStepCount.

runDuration  Alternative way to specify ESMF_Clock’s stopping time; stopTime = startTime + runDuration. Can be positive or negative, consistent with the timeStep’s sign. Mutually exclusive with stopTime and runTimeStepCount.
Alternative way to specify ESMF_Clock’s stopping time; stopTime = startTime + (runTimeStepCount * timeStep). stopTime can be before startTime if timeStep is negative. Mutually exclusive with stopTime and runDuration.

The ESMF_Clock’s reference time. See description in ESMF_ClockCreate() above.

The current time.

The number of times the clock has been timestepped.

Sets the clock’s time-stepping direction. If called with ESMF_DIRECTION_REVERSE, sets the clock in "reverse" mode, causing it to timestep back towards its startTime. If called with ESMF_DIRECTION_FORWARD, sets the clock in normal, "forward" mode, causing it to timestep in the direction of its startTime to stopTime. This holds true for negative timestep clocks as well, which are initialized (created) with stopTime < startTime. The default mode is ESMF_DIRECTION_FORWARD, established at ESMF_ClockCreate(). timeStep can also be specified as an argument at the same time, which allows for a change in magnitude and/or sign of the clock’s timeStep. If not specified with ESMF_DIRECTION_REVERSE, the clock’s current timeStep is effectively negated. If timeStep is specified, its sign is used as specified; it is not negated internally. E.g., if the specified timeStep is negative and the clock is placed in ESMF_DIRECTION_REVERSE, subsequent calls to ESMF_ClockAdvance() will cause the clock’s current time to be decremented by the new timeStep’s magnitude.

The new name for this clock.

Return code; equals ESMF_SUCCESS if there are no errors.

43.5.18 ESMF_ClockStopTimeDisable - Disable a Clock’s stop time

INTERFACE:

```fortran
subroutine ESMF_ClockStopTimeDisable(clock, rc)
ARGUMENTS:

type(ESMF_Clock), intent(inout) :: clock
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Disables a ESMF_Clock’s stop time; ESMF_ClockIsStopTime() will always return false, allowing a clock to run past its stopTime.

The arguments are:
clock  The object instance whose stop time to disable.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.19  ESMF_ClockStopTimeEnable - Enable an Clock’s stop time

INTERFACE:

    subroutine ESMF_ClockStopTimeEnable(clock, stopTime, rc)

ARGUMENTS:

    type(ESMF_Clock), intent(inout)    :: clock
    -- The following arguments require argument keyword syntax (e.g. rc=rc).  --
    type(ESMF_Time), intent(in), optional :: stopTime
    integer,             intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Enables a ESMF_Clock's stop time, allowing ESMF_ClockIsStopTime() to respect the stopTime.

The arguments are:

clock  The object instance whose stop time to enable.

[stopTime]  The stop time to set or reset.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.20  ESMF_ClockSyncToRealTime - Set Clock’s current time to wall clock time

INTERFACE:

    subroutine ESMF_ClockSyncToRealTime(clock, rc)

ARGUMENTS:
type(ESMF_Clock), intent(inout) :: clock
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets a clock’s current time to the wall clock time. It is accurate to the nearest second.

The arguments are:

clock  The object instance to be synchronized with wall clock time.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

43.5.21  ESMF_ClockValidate - Validate a Clock’s properties

INTERFACE:

subroutine ESMF_ClockValidate(clock, rc)

ARGUMENTS:

    type(ESMF_Clock), intent(in) :: clock
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Checks whether a clock is valid. Must have a valid startTime and timeStep. If clock has a stopTime, its currTime must be within startTime to stopTime, inclusive; also startTime’s and stopTime’s calendars must be the same.

The arguments are:

clock  ESMF_Clock to be validated.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
44 Alarm Class

44.1 Description

The Alarm class identifies events that occur at specific Times or specific TimeIntervals by returning a true value at those times or subsequent times, and a false value otherwise.

44.2 Constants

44.2.1 ESMF_ALARMLIST

DESCRIPTION:
Specifies the characteristics of Alarms that populate a retrieved Alarm list.

The type of this flag is:
type(ESMF_AlarmList_Flag)

The valid values are:

ESMF_ALARMLIST_ALL All alarms.
ESMF_ALARMLIST_NEXTRINGING Alarms that will ring before or at the next timestep.
ESMF_ALARMLIST_PREVRINGING Alarms that rang at or since the last timestep.
ESMF_ALARMLIST_RINGING Only ringing alarms.

44.3 Use and Examples

Alarms are used in conjunction with Clocks (see Section 43.1). Multiple Alarms can be associated with a Clock. During the ESMF_ClockAdvance() method, a Clock iterates over its internal Alarms to determine if any are ringing. Alarms ring when a specified Alarm time is reached or exceeded, taking into account whether the time step is positive or negative. In ESMF_DIRECTION_REVERSE (see Section 43.1), alarms ring in reverse, i.e., they begin ringing when they originally ended, and end ringing when they originally began. On completion of the time advance call, the Clock optionally returns a list of ringing alarms.

Each ringing Alarm can then be processed using Alarm methods for identifying, turning off, disabling or resetting the Alarm.

Alarm methods are defined for obtaining the ringing state, turning the ringer on/off, enabling/disabling the Alarm, and getting/setting associated times.

The following example shows how to set and process Alarms.

! !PROGRAM: ESMF_AlarmEx - Alarm examples
! !DESCRIPTION:
! ! This program shows an example of how to create, initialize, and process
! alarms associated with a clock.
!-----------------------------------------------------------------------------------
#include "ESMF.h"

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! instantiate time_step, start, stop, and alarm times
type(ESMF_TimeInterval) :: timeStep, alarmInterval
type(ESMF_Time) :: alarmTime, startTime, stopTime

! instantiate a clock
type(ESMF_Clock) :: clock

! instantiate Alarm lists
integer, parameter :: NUMALARMS = 2
type(ESMF_Alarm) :: alarm(NUMALARMS)

! local variables for Get methods
integer :: ringingAlarmCount ! at any time step (0 to NUMALARMS)

! name, loop counter, result code
character (len=ESMF_MAXSTR) :: name
integer :: i, rc, result

! initialize ESMF framework
call ESMF_Initialize(defaultCalKind=ESMF_CALKIND_GREGORIAN, &
                      defaultlogfilename="AlarmEx.Log", &
                      logkindflag=ESMF_LOGKIND_MULTI, rc=rc)

44.3.1 Clock initialization

This example shows how to create and initialize an ESMF_Clock.

! initialize time interval to 1 day
call ESMF_TimeIntervalSet(timeStep, d=1, rc=rc)

! initialize start time to 9/1/2003
call ESMF_TimeSet(startTime, yy=2003, mm=9, dd=1, rc=rc)

! initialize stop time to 9/30/2003
call ESMF_TimeSet(stopTime, yy=2003, mm=9, dd=30, rc=rc)

! create & initialize the clock with the above values
clock = ESMF_ClockCreate(timeStep, startTime, stopTime=stopTime, &
                         name="The Clock", rc=rc)
44.3.2 Alarm initialization

This example shows how to create and initialize two ESMF_Alarms and associate them with the clock.

! Initialize first alarm to be a one-shot on 9/15/2003 and associate 
! it with the clock
call ESMF_TimeSet(alarmTime, yy=2003, mm=9, dd=15, rc=rc)

alarm(1) = ESMF_AlarmCreate(clock, 
    ringTime=alarmTime, name="Example alarm 1", rc=rc)

! Initialize second alarm to ring on a 1 week interval starting 9/1/2003 
! and associate it with the clock
call ESMF_TimeSet(alarmTime, yy=2003, mm=9, dd=1, rc=rc)
call ESMF_TimeIntervalSet(alarmInterval, d=7, rc=rc)

! Alarm gets default name "Alarm002"
alarm(2) = ESMF_AlarmCreate(clock=clock, ringTime=alarmTime, &
    ringInterval=alarmInterval, rc=rc)

44.3.3 Clock advance and Alarm processing

This example shows how to advance an ESMF_Clock and process any resulting ringing alarms.

! time step clock from start time to stop time
do while (.not.ESMF_ClockIsStopTime(clock, rc=rc))

! perform time step and get the number of any ringing alarms
call ESMF_ClockAdvance(clock, ringingAlarmCount=ringingAlarmCount, &
    rc=rc)
call ESMF_ClockPrint(clock, options="currTime string", rc=rc)

! check if alarms are ringing
if (ringingAlarmCount > 0) then
    print *, "number of ringing alarms = ", ringingAlarmCount
    do i = 1, NUMALARMS
        if (ESMF_AlarmIsRinging(alarm(i), rc=rc)) then

    end do
end if

1003
call ESMF_AlarmGet(alarm(i), name=name, rc=rc)
print *, trim(name), " is ringing!"

! after processing alarm, turn it off
call ESMF_AlarmRingerOff(alarm(i), rc=rc)

end if ! this alarm is ringing
end do ! each ringing alarm
endif ! ringing alarms
end do ! timestep clock

44.3.4 Alarm and Clock destruction

This example shows how to destroy ESMF_Alarms and ESMF_Clocks.

call ESMF_AlarmDestroy(alarm(1), rc=rc)
call ESMF_AlarmDestroy(alarm(2), rc=rc)
call ESMF_ClockDestroy(clock, rc=rc)

! finalize ESMF framework
call ESMF_Finalize(rc=rc)

end program ESMF_AlarmEx

44.4 Restrictions and Future Work

1. **Alarm list allocation factor** The alarm list within a clock is dynamically allocated automatically, 200 alarm references at a time. This constant is defined in both Fortran and C++ with a #define for ease of modification.

2. **Sticky alarm end times in reverse** For sticky alarms, there is an implicit limitation that in order to properly reverse timestep through a ring end time, that time must have already been traversed in the forward direction. This is due to the fact that the Time Manager cannot predict when user code will call ESMF_AlarmRingerOff(). An error message will be logged when this limitation is not satisfied.

3. **Sticky alarm ring interval in reverse** For repeating sticky alarms, it is currently assumed that the ringInterval is constant, so that only the time of the last call to ESMF_AlarmRingerOff() is saved. In ESMF_DIRECTION_REVERSE, this information is used to turn sticky alarms back on. In a future release, ringIntervals will be allowed to be variable, by saving alarm state at every timestep.
44.5 Design and Implementation Notes

The Alarm class is designed as a deep, dynamically allocatable class, based on a pointer type. This allows for both indirect and direct manipulation of alarms. Indirect alarm manipulation is where ESMF_Alarm API methods, such as ESMF_AlarmRingerOff(), are invoked on alarm references (pointers) returned from ESMF_Clock queries such as "return ringing alarms." Since the method is performed on an alarm reference, the actual alarm held by the clock is affected, not just a user's local copy. Direct alarm manipulation is the more common case where alarm API methods are invoked on the original alarm objects created by the user.

For consistency, the ESMF_Clock class is also designed as a deep, dynamically allocatable class.

An additional benefit from this approach is that Clocks and Alarms can be created and used from anywhere in a user's code without regard to the scope in which they were created. In constrast, statically created Alarms and Clocks would disappear if created within a user's routine that returns, whereas dynamically allocated Alarms and Clocks will persist until explicitly destroyed by the user.

44.6 Class API

44.6.1 ESMF_AlarmAssignment(=) - Assign an Alarm to another Alarm

INTERFACE:

interface assignment(=)
alarm1 = alarm2

ARGUMENTS:

type(ESMF_Alarm) :: alarm1
type(ESMF_Alarm) :: alarm2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign alarm1 as an alias to the same ESMF_Alarm object in memory as alarm2. If alarm2 is invalid, then alarm1 will be equally invalid after the assignment.

The arguments are:

alarm1 The ESMF_Alarm object on the left hand side of the assignment.
alarm2 The ESMF_Alarm object on the right hand side of the assignment.
44.6.2  ESMF_AlarmOperator(==) - Test if Alarm 1 is equal to Alarm 2

INTERFACE:

interface operator(==)
  if (alarm1 == alarm2) then ... endif
  OR
  result = (alarm1 == alarm2)
end interface

RETURN VALUE:

logical :: result

ARGUMENTS:

type(ESMF_Alarm), intent(in) :: alarm1

type(ESMF_Alarm), intent(in) :: alarm2

DESCRIPTION:

Overloads the (==) operator for the ESMF_Alarm class. Compare two alarms for equality; return .true. if equal, .false. otherwise. Comparison is based on IDs, which are distinct for newly created alarms and identical for alarms created as copies.

If either side of the equality test is not in the ESMF_INIT_CREATED status an error will be logged. However, this does not affect the return value, which is .true. when both sides are in the same status, and .false. otherwise.

The arguments are:

alarm1  The ESMF_Alarm object on the left hand side of the equality operation.

alarm2  The ESMF_Alarm object on the right hand side of the equality operation.

44.6.3  ESMF_AlarmOperator(/=) - Test if Alarm 1 is not equal to Alarm 2

INTERFACE:

interface operator(/=)
  if (alarm1 /= alarm2) then ... endif
  OR
  result = (alarm1 /= alarm2)
end interface

RETURN VALUE:

logical :: result

ARGUMENTS:
type(ESMF_Alarm), intent(in) :: alarm1
type(ESMF_Alarm), intent(in) :: alarm2

DESCRIPTION:

Overloads the (/=) operator for the ESMF_Alarm class. Compare two alarms for inequality; return .true. if not equal, .false. otherwise. Comparison is based on IDs, which are distinct for newly created alarms and identical for alarms created as copies.

If either side of the equality test is not in the ESMF_INIT_CREATED status an error will be logged. However, this does not affect the return value, which is .true. when both sides are not in the same status, and .false. otherwise.

The arguments are:

alarm1  The ESMF_Alarm object on the left hand side of the non-equality operation.
alarm2  The ESMF_Alarm object on the right hand side of the non-equality operation.

44.6.4  ESMF_AlarmCreate - Create a new ESMF Alarm

INTERFACE:

! Private name; call using ESMF_AlarmCreate()
function ESMF_AlarmCreateNew(clock, &
   ringTime, ringInterval, stopTime, ringDuration, ringTimeStepCount, &
   refTime, enabled, sticky, name, rc)

RETURN VALUE:

type(ESMF_Alarm) :: ESMF_AlarmCreateNew

ARGUMENTS:

   type(ESMF_Clock), intent(in) :: clock
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_Time), intent(in), optional :: ringTime
   type(ESMF_TimeInterval), intent(in), optional :: ringInterval
   type(ESMF_Time), intent(in), optional :: stopTime
   type(ESMF_TimeInterval), intent(in), optional :: ringDuration
   integer, intent(in), optional :: ringTimeStepCount
   type(ESMF_Time), intent(in), optional :: refTime
   logical, intent(in), optional :: enabled
   logical, intent(in), optional :: sticky
   character (len=*)&, intent(in), optional :: name
   integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Creates and sets the initial values in a new ESMF_Alarm.

In ESMF_DIRECTION_REVERSE (see Section 43.1), alarms ring in reverse, i.e., they begin ringing when they originally ended, and end ringing when they originally began.

The arguments are:

- **clock** The clock with which to associate this newly created alarm.

- **[ringTime]** The ring time for a one-shot alarm or the first ring time for a repeating (interval) alarm. Must specify at least one of ringTime or ringInterval.

- **[ringInterval]** The ring interval for repeating (interval) alarms. If ringTime is not also specified (first ring time), it will be calculated as the clock's current time plus ringInterval. Must specify at least one of ringTime or ringInterval.

- **[stopTime]** The stop time for repeating (interval) alarms. If not specified, an interval alarm will repeat forever.

- **[ringDuration]** The absolute ring duration. If not sticky (see argument below), alarms rings for ringDuration, then turns itself off. Default is zero (unused). Mutually exclusive with ringTimeStepCount (below); used only if set to a non-zero duration and ringTimeStepCount is 1 (see below). See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

- **[ringTimeStepCount]** The relative ring duration. If not sticky (see argument below), alarms rings for ringTimeStepCount, then turns itself off. Default is 1: a non-sticky alarm will ring for one clock time step. Mutually exclusive with ringDuration (above); used if ringTimeStepCount > 1. If ringTimeStepCount is 1 (default) and ringDuration is non-zero, ringDuration is used (see above), otherwise ringTimeStepCount is used. See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

- **[refTime]** The reference (i.e. base) time for an interval alarm.

- **[enabled]** Sets the enabled state; default is on (true). If disabled, an alarm will not function at all. See also ESMF_AlarmEnable(), ESMF_AlarmDisable().

- **[sticky]** Sets the sticky state; default is on (true). If sticky, once an alarm is ringing, it will remain ringing until turned off manually via a user call to ESMF_AlarmRingerOff(). If not sticky, an alarm will turn itself off after a certain ring duration specified by either ringDuration or ringTimeStepCount (see above). There is an implicit limitation that in order to properly reverse timestep through a ring end time in ESMF_DIRECTION_REVERSE, that time must have already been traversed in the forward direction. This is due to the fact that the Time Manager cannot predict when user code will call ESMF_AlarmRingerOff(). An error message will be logged when this limitation is not satisfied. See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

- **[name]** The name for the newly created alarm. If not specified, a default unique name will be generated: "AlarmNNN" where NNN is a unique sequence number from 001 to 999.

- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
44.6.5 ESMF_AlarmCreate - Create a copy of an existing ESMF Alarm

INTERFACE:

! Private name; call using ESMF_AlarmCreate()
function ESMF_AlarmCreateCopy(alarm, rc)

RETURN VALUE:

type(ESMF_Alarm) :: ESMF_AlarmCreateCopy

ARGUMENTS:

type(ESMF_Alarm), intent(in) :: alarm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Creates a complete (deep) copy of a given ESMF_Alarm. The returned ESMF_Alarm copy is associated with the same ESMF_Clock as the original ESMF_Alarm. If desired, use ESMF_AlarmSet(...clock=...) to re-associate the ESMF_Alarm copy with a different ESMF_Clock.

The arguments are:

alarm The ESMF_Alarm to copy.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.6 ESMF_AlarmDestroy - Release resources associated with an Alarm

INTERFACE:

subroutine ESMF_AlarmDestroy(alarm, rc)

ARGUMENTS:

type(ESMF_Alarm), intent(inout) :: alarm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Releases resources associated with this ESMF_Alarm. Also removes this ESMF_Alarm from its associated ESMF_Clock's list of ESMF_Alarms (removes the ESMF_Alarm pointer from the list).

The arguments are:

alarm Release resources associated with this ESMF_Alarm and mark the object as invalid. It is an error to pass this object into any other routines after being destroyed.

[rc ] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.7 ESMF_AlarmDisable - Disable an Alarm

INTERFACE:

```fortran
subroutine ESMF_AlarmDisable(alarm, rc)
ARGUMENTS:

    type(ESMF_Alarm), intent(inout) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Disables an ESMF_Alarm.

The arguments are:

alarm The object instance to disable.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
44.6.8 ESMF_AlarmEnable - Enable an Alarm

INTERFACE:

```fortran
subroutine ESMF_AlarmEnable(alarm, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_Alarm), intent(inout) :: alarm
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Enables an `ESMF_Alarm` to function.

The arguments are:

**alarm** The object instance to enable.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

44.6.9 ESMF_AlarmGet - Get Alarm properties

INTERFACE:

```fortran
subroutine ESMF_AlarmGet(alarm, &
  clock, ringTime, prevRingTime, ringInterval, stopTime, ringDuration, &
  ringTimeStepCount, timeStepRingingCount, ringBegin, ringEnd, &
  refTime, ringing, ringingOnPrevTimeStep, enabled, sticky, name, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_Alarm), intent(in) :: alarm
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_Clock), intent(out), optional :: clock
  type(ESMF_Time), intent(out), optional :: ringTime
  type(ESMF_Time), intent(out), optional :: prevRingTime
  type(ESMF_TimeInterval), intent(out), optional :: ringInterval
  type(ESMF_TimeInterval), intent(out), optional :: ringInterval
  type(ESMF_Time), intent(out), optional :: prevRingTime
```

```fortran
  type(ESMF_Time), intent(out), optional :: ringInterval
  type(ESMF_TimeInterval), intent(out), optional :: ringInterval
```
type(ESMF_Time),    intent(out), optional :: stopTime
type(ESMF_TimeInterval), intent(out), optional :: ringDuration
integer,    intent(out), optional :: ringTimeStepCount
integer,    intent(out), optional :: timeStepRingingCount
type(ESMF_Time),    intent(out), optional :: ringBegin
type(ESMF_Time),    intent(out), optional :: refTime
logical,    intent(out), optional :: ringing
logical,    intent(out), optional :: ringingOnPrevTimeStep
logical,    intent(out), optional :: enabled
logical,    intent(out), optional :: sticky
character (len=*),    intent(out), optional :: name
integer,    intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets one or more of an ESMF_Alarm’s properties.

The arguments are:

alarm    The object instance to query.

[clock]    The associated clock.

[ringTime]    The ring time for a one-shot alarm or the next repeating alarm.

[prevRingTime]    The previous ring time.

[ringInterval]    The ring interval for repeating (interval) alarms.

[stopTime]    The stop time for repeating (interval) alarms.

[ringDuration]    The ring duration. Mutually exclusive with ringTimeStepCount (see below).

[ringTimeStepCount]    The number of time steps comprising the ring duration. Mutually exclusive with ringDuration (see above).

[timeStepRingingCount]    The number of time steps for which the alarm has been ringing thus far. Used internally for tracking ringTimeStepCount ring durations (see above). Mutually exclusive with ringBegin (see below). Increments in ESMF_DIRECTION_FORWARD and decrements in ESMF_DIRECTION_REVERSE; see Section 43.1.

[ringBegin]    The time when the alarm began ringing. Used internally for tracking ringDuration (see above). Mutually exclusive with timeStepRingingCount (see above).

[ringEnd]    The time when the alarm ended ringing. Used internally for re-ringing alarm in ESMF_DIRECTION_REVERSE.

[refTime]    The reference (i.e. base) time for an interval alarm.

[ringing]    The current ringing state. See also ESMF_AlarmRingerOn(), ESMF_AlarmRingerOff().
[ringingOnPrevTimeStep] The ringing state upon the previous time step. Same as ESMF_AlarmWasPrevRinging().

[enabled] The enabled state. See also ESMF_AlarmEnable(), ESMF_AlarmDisable().

[sticky] The sticky state. See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

[name] The name of this alarm.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.10 ESMF_AlarmIsEnabled - Check if Alarm is enabled

INTERFACE:

    function ESMF_AlarmIsEnabled(alarm, rc)

RETURN VALUE:

    logical :: ESMF_AlarmIsEnabled

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Check if ESMF_Alarm is enabled.

The arguments are:

alarm The object instance to check for enabled state.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
44.6.11  ESMF_AlarmIsRinging - Check if Alarm is ringing

INTERFACE:

    function ESMF_AlarmIsRinging(alarm, rc)

RETURN VALUE:

    logical :: ESMF_AlarmIsRinging

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Check if ESMF_Alarm is ringing.

See also method ESMF_ClockGetAlarmList(clock, ESMF_ALARMLIST_RINGING, ...) to get a list of all ringing alarms belonging to an ESMF_Clock.

The arguments are:

alarm  The alarm to check for ringing state.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

44.6.12  ESMF_AlarmIsSticky - Check if Alarm is sticky

INTERFACE:

    function ESMF_AlarmIsSticky(alarm, rc)

RETURN VALUE:

    logical :: ESMF_AlarmIsSticky
ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Check if alarm is sticky.

The arguments are:

alarm The object instance to check for sticky state.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.13 ESMF_AlarmNotSticky - Unset an Alarm's sticky flag

INTERFACE:

    subroutine ESMF_AlarmNotSticky(alarm, &
                                       ringDuration, ringTimeStepCount, rc)

ARGUMENTS:

    type(ESMF_Alarm), intent(inout) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_TimeInterval), intent(in), optional :: ringDuration
    integer, intent(in), optional :: ringTimeStepCount
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Unset an ESMF_Alarm's sticky flag; once alarm is ringing, it turns itself off after ringDuration.

The arguments are:
alarm  The object instance to unset sticky.

[ringDuration]  If not sticky, alarms rings for ringDuration, then turns itself off. Mutually exclu-
sive with ringTimeStepCount (see below and full description in method ESMF_AlarmCreate() or
ESMF_AlarmSet()).

[ringTimeStepCount]  If not sticky, alarms rings for ringTimeStepCount, then turns itself off. Mutually
exclusive with ringDuration (see above and full description in method ESMF_AlarmCreate() or
ESMF_AlarmSet()).

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

44.6.14  ESMF_AlarmPrint - Print Alarm information

INTERFACE:

    subroutine ESMF_AlarmPrint(alarm, options, rc)

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    character (len=*) , intent(in), optional :: options
    integer, intent(out), optional :: rc

DESCRIPTION:

Prints out an ESMF_Alarm’s properties to stdout, in support of testing and debugging. The options control the
type of information and level of detail.

The arguments are:

alarm  ESMF_Alarm to be printed out.

[options]  Print options. If none specified, prints all alarm property values.
    "clock" - print the associated clock’s name.
    "enabled" - print the alarm’s ability to ring.
    "name" - print the alarm’s name.
    "prevRingTime" - print the alarm’s previous ring time.
    "ringBegin" - print time when the alarm actually begins to ring.
    "ringDuration" - print how long this alarm is to remain ringing.
    "ringEnd" - print time when the alarm actually ends ringing.
    "ringing" - print the alarm’s current ringing state.
    "ringingOnPrevTimeStep" - print whether the alarm was ringing immediately after the previous clock time step.
    "ringInterval" - print the alarm’s periodic ring interval.
    "ringTime" - print the alarm’s next time to ring.
    "ringTimeStepCount" - print how long this alarm is to remain ringing, in terms of a number of clock time steps.
    "refTime" - print the alarm’s interval reference (base) time.
"sticky" - print whether the alarm must be turned off manually.
"stopTime" - print when alarm intervals end.
"timeStepRingingCount" - print the number of time steps the alarm has been ringing thus far.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.15 ESMF_AlarmRingerOff - Turn off an Alarm

INTERFACE:

    subroutine ESMF_AlarmRingerOff(alarm, rc)

ARGUMENTS:

    type(ESMFAlarm), intent(inout) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface com- 
piles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Turn off an ESMF_Alarm; unsets ringing state. For a sticky alarm, this method must be called to turn off its ring-
ing state. This is true for either ESMF_DIRECTION_FORWARD (default) or ESMF_DIRECTION_REVERSE. See 
Section 43.1

The arguments are:

alarm The object instance to turn off.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.16 ESMF_AlarmRingerOn - Turn on an Alarm

INTERFACE:

    subroutine ESMF_AlarmRingerOn(alarm, rc)
ARGUMENTS:

```plaintext
type(ESMF_Alarm), intent(inout) :: alarm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Turn on an ESMF_Alarm; sets ringing state.

The arguments are:

**alarm** The object instance to turn on.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

44.6.17 ESMF_AlarmSet - Set Alarm properties

INTERFACE:

```plaintext
subroutine ESMF_AlarmSet(alarm, &
clock, ringTime, ringInterval, stopTime, ringDuration, &
ringTimeStepCount, refTime, ringing, enabled, sticky, name, rc)
```

ARGUMENTS:

```plaintext
type(ESMF_Alarm), intent(inout) :: alarm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Clock), intent(in), optional :: clock
type(ESMF_Time), intent(in), optional :: ringTime
type(ESMF_TimeInterval), intent(in), optional :: ringInterval
type(ESMF_Time), intent(in), optional :: stopTime
type(ESMF_TimeInterval), intent(in), optional :: ringDuration
integer, intent(in), optional :: ringTimeStepCount
type(ESMF_Time), intent(in), optional :: refTime
logical, intent(in), optional :: ringing
logical, intent(in), optional :: enabled
logical, intent(in), optional :: sticky
character (len=*) , intent(in), optional :: name
integer, intent(out), optional :: rc
```
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets/resets one or more of the properties of an ESMF_Alarm that was previously initialized via ESMF_AlarmCreate().

The arguments are:

**alarm**  The object instance to set.

**[clock]** Re-associates this alarm with a different clock.

**[ringTime]** The next ring time for a one-shot alarm or a repeating (interval) alarm.

**[ringInterval]** The ring interval for repeating (interval) alarms.

**[stopTime]** The stop time for repeating (interval) alarms.

**[ringDuration]** The absolute ring duration. If not sticky (see argument below), alarms rings for ringDuration, then turns itself off. Default is zero (unused). Mutually exclusive with ringTimeStepCount (below); used only if set to a non-zero duration and ringTimeStepCount is 1 (see below). See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

**[ringTimeStepCount]** The relative ring duration. If not sticky (see argument below), alarms rings for ringTimeStepCount, then turns itself off. Default is 1: a non-sticky alarm will ring for one clock time step. Mutually exclusive with ringDuration (above); used if ringTimeStepCount > 1. If ringTimeStepCount is 1 (default) and ringDuration is non-zero, ringDuration is used (see above), otherwise ringTimeStepCount is used. See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

**[refTime]** The reference (i.e. base) time for an interval alarm.

**[ringing]** Sets the ringing state. See also ESMF_AlarmRingerOn(), ESMF_AlarmRingerOff().

**[enabled]** Sets the enabled state. If disabled, an alarm will not function at all. See also ESMF_AlarmEnable(), ESMF_AlarmDisable().

**[sticky]** Sets the sticky state. If sticky, once an alarm is ringing, it will remain ringing until turned off manually via a user call to ESMF_AlarmRingerOff(). If not sticky, an alarm will turn itself off after a certain ring duration specified by either ringDuration or ringTimeStepCount (see above). There is an implicit limitation that in order to properly reverse timestep through a ring end time in ESMF_DIRECTION_REVERSE, that time must have already been traversed in the forward direction. This is due to the fact that the Time Manager cannot predict when user code will call ESMF_AlarmRingerOff(). An error message will be logged when this limitation is not satisfied. See also ESMF_AlarmSticky(), ESMF_AlarmNotSticky().

**[name]** The new name for this alarm.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
44.6.18  ESMF_AlarmSticky - Set an Alarm’s sticky flag

INTERFACE:

    subroutine ESMF_AlarmSticky(alarm, rc)

ARGUMENTS:

    type(ESMF_Alarm), intent(inout) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer,          intent(out), optional :: rc

STATUS:

    •  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Set an ESMF_Alarm’s sticky flag: once alarm is ringing, it remains ringing until ESMF_AlarmRingerOff() is called. There is an implicit limitation that in order to properly reverse timestep through a ring end time in ESMF_DIRECTION_REVERSE, that time must have already been traversed in the forward direction. This is due to the fact that an ESMF_Alarm cannot predict when user code will call ESMF_AlarmRingerOff(). An error message will be logged when this limitation is not satisfied.

The arguments are:

alarm  The object instance to be set sticky.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

44.6.19  ESMF_AlarmValidate - Validate an Alarm’s properties

INTERFACE:

    subroutine ESMF_AlarmValidate(alarm, rc)

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer,          intent(out), optional :: rc
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Performs a validation check on an ESMF_Alarm’s properties. Must have a valid ringTime, set either directly or indirectly via ringInterval. See ESMF_AlarmCreate().

The arguments are:

alarm ESMF_Alarm to be validated.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

44.6.20 ESMF_AlarmWasPrevRinging - Check if Alarm was ringing on the previous Clock timestep

INTERFACE:

    function ESMF_AlarmWasPrevRinging(alarm, rc)

RETURN VALUE:

    logical :: ESMF_AlarmWasPrevRinging

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Check if ESMF_Alarm was ringing on the previous clock timestep.

See also method ESMF_ClockGetAlarmList(clock, ESMF_ALARMLIST_PREVRINGLE, ...) get a list of all alarms belonging to a ESMF_Clock that were ringing on the previous time step.

The arguments are:

alarm The object instance to check for previous ringing state.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
44.6.21  ESMF_AlarmWillRingNext - Check if Alarm will ring upon the next Clock timestep

INTERFACE:

    function ESMF_AlarmWillRingNext(alarm, timeStep, rc)

RETURN VALUE:

    logical :: ESMF_AlarmWillRingNext

ARGUMENTS:

    type(ESMF_Alarm), intent(in) :: alarm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_TimeInterval), intent(in), optional :: timeStep
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Check if ESMF_Alarm will ring on the next clock timestep, either the current clock timestep or a passed-in timestep. See also method ESMF_ClockGetAlarmList(clock, ESMF_ALARMLIST_NEXTRINGING, ...) to get a list of all alarms belonging to a ESMF_Clock that will ring on the next time step.

The arguments are:

alarm  The alarm to check for next ringing state.

[timeStep]  Optional timestep to use instead of the clock’s.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

45  Config Class

45.1  Description

ESMF Configuration Management is based on NASA DAO’s Inpak 90 package, a Fortran 90 collection of routines/functions for accessing Resource Files in ASCII format. The package is optimized for minimizing formatted I/O, performing all of its string operations in memory using Fortran intrinsic functions.
45.1.1 Package history

The ESMF Configuration Management Package was evolved by Leonid Zaslavsky and Arlindo da Silva from Ipack90 package created by Arlindo da Silva at NASA DAO.

Back in the 70's Eli Isaacson wrote IOPACK in Fortran 66. In June of 1987 Arlindo da Silva wrote Inpak77 using Fortran 77 string functions; Inpak 77 is a vastly simplified IOPACK, but has its own goodies not found in IOPACK. Inpak 90 removes some obsolete functionality in Inpak77, and parses the whole resource file in memory for performance.

45.1.2 Resource files

A Resource File (RF) is a text file consisting of list of label-value pairs. There is a limit of 250 characters per line and the Resource File can contain a maximum of 200 records. Each label should be followed by some data, the value. An example Resource File follows. It is the file used in the example below.

```plaintext
# This is an example Resource File.
# It contains a list of <label,value> pairs.
# The colon after the label is required.
# The values after the label can be an list.
# Multiple types are authorized.

my_file_names: jan87.dat jan88.dat jan89.dat # all strings
constants: 3.1415 25 # float and integer
my_favorite_colors: green blue 022

# Or, the data can be a list of single value pairs.
# It is simplier to retrieve data in this format:

radius_of_the_earth: 6.37E6
parameter_1: 89
parameter_2: 78.2
input_file_name: dummy_input.netcdf

# Or, the data can be located in a table using the following
# syntax:

my_table_name::
  1000 3000 263.0
  925 3000 263.0
  850 3000 263.0
  700 3000 269.0
  500 3000 287.0
  400 3000 295.8
  300 3000 295.8
::
```
Note that the colon after the label is required and that the double colon is required to declare tabular data.

Resource files are intended for random access (except between ::’s in a table definition). This means that order in which a particular label-value pair is retrieved is not dependent upon the original order of the pairs. The only exception to this, however, is when the same label appears multiple times within the Resource File.

### 45.2 Use and Examples

This example/test code performs simple Config/Resource File routines. It does not include attaching a Config to a component. The important thing to remember there is that you can have one Config per component.

There are two methodologies for accessing data in a Resource File. This example will demonstrate both.

Note the API section contains a complete description of arguments in the methods/functions demonstrated in this example.

#### 45.2.1 Variable declarations

The following are the variable declarations used as arguments in the following code fragments. They represent the locals names for the variables listed in the Resource File (RF). Note they do not need to be the same.

```fortran
character(ESMF_MAXPATHLEN) :: fname ! config file name
character(ESMF_MAXPATHLEN) :: fn1, fn2, fn3, input_file ! strings to be read in
integer :: rc ! error return code (0 is OK)
integer :: i_n ! the first constant in the RF
real :: param_1 ! the second constant in the RF
real :: radius ! radius of the earth
real :: table(7,3) ! an array to hold the table in the RF

type(ESMF_Config) :: cf ! the Config itself
```

#### 45.2.2 Creation of a Config

While there are two methodologies for accessing the data within a Resource File, there is only one way to create the initial Config and load its ASCII text into memory. This is the first step in the process.

Note that subsequent calls to ESMF_ConfigLoadFile will OVERWRITE the current Config NOT append to it. There is no means of appending to a Config.

```fortran
cf = ESMF_ConfigCreate(rc=rc) ! Create the empty Config
fname = "myResourceFile.rc" ! Name the Resource File
call ESMF_ConfigLoadFile(cf, fname, rc=rc) ! Load the Resource File into the empty Config
```

#### 45.2.3 How to retrieve a label with a single value

The first method for retrieving information from the Resource File takes advantage of the <label,value> relationship within the file and access the data in a dictionary-like manner. This is the simplest methodology, but it does imply the
use of only one value per label in the Resource File.

Remember, that the order in which a particular label/value pair is retrieved is not dependent upon the order which they exist within the Resource File.

```fortran
    call ESMF_ConfigGetAttribute(cf, radius, label='radius_of_the_earth:', &
                              default=1.0, rc=rc)
```

Note that the colon must be included in the label string when using this methodology. It is also important to provide a default value in case the label does not exist in the file.

This methodology works for all types. The following is an example of retrieving a string:

```fortran
    call ESMF_ConfigGetAttribute(cf, input_file, label='input_file_name:', &
                              default='./default.nc', rc=rc)
```

The same code fragment can be used to demonstrate what happens when the label is not present. Note that "file_name" does not exist in the Resource File. The result of its absence is the default value provided in the call.

```fortran
    call ESMF_ConfigGetAttribute(cf, input_file, label='file_name:', &
                              default='./default.nc', rc=rc)
```

### 45.2.4 How to retrieve a label with multiple values

When there are multiple, mixed-typed values associated with a label, the values can be retrieved in two steps: 1) Use `ESMF_ConfigFindLabel()` to find the label in the Config class; 2) use `ESMF_ConfigGetAttribute()` without the optional 'label' argument to retrieve the values one at a time, reading from left to right in the record.

A second reminder that the order in which a particular label/value pair is retrieved is not dependent upon the order which they exist within the Resource File. The label used in this method allows the user to skip to any point in the file.

```fortran
    call ESMF_ConfigFindLabel(cf, 'constants:', rc=rc) ! Step a) Find the ! label
```

Two constants, radius and i_n, can now be retrieved without having to specify their label or use an array. They are also different types.

```fortran
    call ESMF_ConfigGetAttribute(cf, param_1, rc=rc) ! Step b) read in the ! first constant in ! the sequence
    call ESMF_ConfigGetAttribute(cf, i_n, rc=rc) ! Step c) read in the ! second constant in ! the sequence
```

This methodology also works with strings.
call ESMF_ConfigFindLabel(cf, 'my_file_names:', &
   rc=rc)  ! Step a) find the label

call ESMF_ConfigGetAttribute(cf, fn1, &
   rc=rc)  ! Step b) retrieve the 1st filename
call ESMF_ConfigGetAttribute(cf, fn2, &
   rc=rc)  ! Step c) retrieve the 2nd filename
call ESMF_ConfigGetAttribute(cf, fn3, &
   rc=rc)  ! Step d) retrieve the 3rd filename

45.2.5 How to retrieve a table

To access tabular data, the user must use the multi-value method.

    call ESMF_ConfigFindLabel(cf, 'my_table_name::', &
       rc=rc)  ! Step a) Set the label location to the
               ! beginning of the table

Subsequently, call ESMF_ConfigNextLine() is used to move the location to the next row of the table. The example table in the Resource File contains 7 rows and 3 columns (7,3).

    do i = 1, 7
       call ESMF_ConfigNextLine(cf, rc=rc)  ! Step b) Increment the rows
    do j = 1, 3 ! Step c) Fill in the table
       call ESMF_ConfigGetAttribute(cf, table(i,j), rc=rc)
    enddo
    enddo

45.2.6 Destruction of a Config

The work with the configuration file cf is finalized by call to ESMF_ConfigDestroy():

    call ESMF_ConfigDestroy(cf, rc=rc)  ! Destroy the Config

45.3 Class API

45.3.1 ESMF_ConfigAssignment(=) - Config assignment

INTERFACE:

    interface assignment(=)
      config1 = config2
ARGUMENTS:

    type(ESMF_Config) :: config1
    type(ESMF_Config) :: config2

DESCRIPTION:

Assign config1 as an alias to the same ESMF_Config object in memory as config2. If config2 is invalid, then config1 will be equally invalid after the assignment.

The arguments are:

**config1** The ESMF_Config object on the left hand side of the assignment.

**config2** The ESMF_Config object on the right hand side of the assignment.

---

45.3.2 ESMF_ConfigOperator(==) - Test if Config objects are equivalent

INTERFACE:

    interface operator(==)
    if (config1 == config2) then ... endif
    OR
    result = (config1 == config2)

RETURN VALUE:

    configical :: result

ARGUMENTS:

    type(ESMF_Config), intent(in) :: config1
    type(ESMF_Config), intent(in) :: config2

DESCRIPTION:

Overloads the (==) operator for the ESMF_Config class. Compare two configs for equality; return .true. if equal, .false. otherwise. Comparison is based on whether the objects are distinct, as with two newly created objects, or are simply aliases to the same object as would be the case when assignment was involved.

The arguments are:

**config1** The ESMF_Config object on the left hand side of the equality operation.

**config2** The ESMF_Config object on the right hand side of the equality operation.
45.3.3 ESMF_ConfigOperator( /= ) - Test if Config objects are not equivalent

INTERFACE:

interface operator( /=)
  if (config1 /= config2) then ... endif
  OR
  result = (config1 /= config2)
end interface

RETURN VALUE:

configical :: result

ARGUMENTS:

type(ESMF_Config), intent(in) :: config1

type(ESMF_Config), intent(in) :: config2

DESCRIPTION:

Overloads the ( /= ) operator for the ESMF_Config class. Compare two configs for equality; return .true. if not equivalent, .false. otherwise. Comparison is based on whether the Config objects are distinct, as with two newly created objects, or are simply aliases to the same object as would be the case when assignment was involved.

The arguments are:

config1  The ESMF_Config object on the left hand side of the equality operation.
config2  The ESMF_Config object on the right hand side of the equality operation.

45.3.4 ESMF_ConfigCreate - Instantiate a Config object

INTERFACE:

  type(ESMF_Config) function ESMF_ConfigCreate(rc)

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer,intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Instantiates an ESMF_Config object for use in subsequent calls.
The arguments are:

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

45.3.5 ESMF_ConfigDestroy - Destroy a Config object

INTERFACE:

subroutine ESMF_ConfigDestroy(config, rc)

ARGUMENTS:

type(ESMF_Config), intent(inout) :: config
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroys the config object.
The arguments are:

config Already created ESMF_Config object.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

45.3.6 ESMF_ConfigFindLabel - Find a label

INTERFACE:

subroutine ESMF_ConfigFindLabel(config, label, isPresent, rc)

ARGUMENTS:
type(ESMF_Config), intent(inout) :: config
character(len=*), intent(in) :: label

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
logical, intent(out), optional :: isPresent
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

• This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

6.1.0 Added the isPresent argument. Allows detection of end-of-line condition to be separate from the rc.

DESCRIPTION:

Finds the label (key) string in the config object.

Since the search is done by looking for a string, possibly multi-worded, in the whole Config object, it is important to use special conventions to distinguish labels from other words. This is done in the Resource File by using the NASA/DAO convention to finish line labels with a colon (:) and table labels with a double colon (::).

The arguments are:

config Already created ESMF_Config object.
label Identifying label.

[isPresent] Set to .true. if the item is found.

[rc] Return code; equals ESMF_SUCCESS if there are no errors. If the label is not found, and the isPresent argument is not present, an error is returned.

45.3.7 ESMF_ConfigGetAttribute - Get a value

INTERFACE:

subroutine ESMF_ConfigGetAttribute(config, <value>, &
    label, default, rc)

ARGUMENTS:

type(ESMF_Config), intent(inout) :: config
<value argument>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets a value from the config object. When the value is a sequence of characters it will be terminated by the first white space.

Supported values for <value argument> are:

character(len=*) intent(out) :: value
real(ESMF_KIND_R4), intent(out) :: value
real(ESMF_KIND_R8), intent(out) :: value
integer(ESMF_KIND_I4), intent(out) :: value
integer(ESMF_KIND_I8), intent(out) :: value
logical, intent(out) :: value

The arguments are:

config Already created ESMF_Config object.
<value argument> Returned value.
[label] Identifying label.
[default] Default value if label is not found in config object.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

45.3.8 ESMF_ConfigGetAttribute - Get a list of values

INTERFACE:

subroutine ESMF_ConfigGetAttribute(config, <value list argument>, &
count, label, default, rc)

ARGUMENTS:
type(ESMF_Config), intent(inout) :: config
<value list argument>, see below for values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in) optional :: count
character(len=*) , intent(in), optional :: label
character(len=*) , intent(in), optional :: default
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets a list of values from the config object.
Supported values for <value list argument> are:

real(ESMF_KIND_R4), intent(inout) :: valueList(:)
real(ESMF_KIND_R8), intent(inout) :: valueList(:)
integer(ESMF_KIND_I4), intent(inout) :: valueList(:)
integer(ESMF_KIND_I8), intent(inout) :: valueList(:)
logical, intent(inout) :: valueList(:)

The arguments are:

config  Already created ESMF_Config object.
<value list argument>  Returned value.
count  Number of returned values expected.
[label]  Identifing label.
[default]  Default value if label is not found in config object.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

45.3.9  ESMF_ConfigGetChar - Get a character

INTERFACE:

subroutine ESMF_ConfigGetChar(config, value, &
label, default, rc)

ARGUMENTS:
type(ESMF_Config), intent(inout) :: config
character, intent(out) :: value

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len=+), intent(in), optional :: label
character, intent(in), optional :: default
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets a character value from the config object.

The arguments are:

config  Already created ESMF_Config object.
value   Returned value.
[label] Identifying label.
[default] Default value if label is not found in configuration object.
[rc]   Return code; equals ESMF_SUCCESS if there are no errors.

45.3.10  ESMF_ConfigGetDim - Get table sizes

INTERFACE:

subroutine ESMF_ConfigGetDim(config, lineCount, columnCount, &
                              label, rc)

ARGUMENTS:

      type(ESMF_Config), intent(inout) :: config
      integer, intent(out) :: lineCount
      integer, intent(out) :: columnCount

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
      character(len=+), intent(in), optional :: label
      integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Returns the number of lines in the table in `lineCount` and the maximum number of words in a table line in `columnCount`.

The arguments are:

- `config` Already created ESMF_Config object.
- `lineCount` Returned number of lines in the table.
- `columnCount` Returned maximum number of words in a table line.
- `[label]` Identifying label (if present), otherwise current line.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.

### 45.3.11 ESMF_ConfigGetLen - Get the length of the line in words

INTERFACE:

```fortran
integer function ESMF_ConfigGetLen(config, label, rc)
```

ARGUMENTS:

- `type(ESMF_Config), intent(inout) :: config`
  -- The following arguments require argument keyword syntax (e.g. `rc=rc`). --
- `character(len=*), intent(in), optional :: label`
- `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Gets the length of the line in words by counting words disregarding types. Returns the word count as an integer.

The arguments are:

- `config` Already created ESMF_Config object.
- `[label]` Identifying label. If not specified, use the current line.
- `[rc]` Return code; equals ESMF_SUCCESS if there are no errors.
45.3.12 ESMF_ConfigLoadFile - Load resource file into memory

INTERFACE:

    subroutine ESMF_ConfigLoadFile(config, filename, &
         delayout, unique, rc)

ARGUMENTS:

    type(ESMF_Config), intent(inout) :: config
    character(len=*), intent(in) :: filename
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_DELayout), intent(in), optional :: delayout
    logical, intent(in), optional :: unique
    integer, intent(out), optional :: rc

STATUS:

    • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Resource file with filename is loaded into memory.

The arguments are:

config  Already created ESMF_Config object.
filename  Configuration file name.
[delayout] ESMF_DELayout associated with this config object.
[unique] If specified as true, uniqueness of labels are checked and error code set if duplicates found.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

45.3.13 ESMF_ConfigNextLine - Find next line

INTERFACE:

    subroutine ESMF_ConfigNextLine(config, tableEnd, rc)

ARGUMENTS:
 type(ESMF_Config), intent(inout) :: config
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
 logical, intent(out), optional :: tableEnd
 integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Selects the next line (for tables).

The arguments are:

config Already created ESMF_Config object.
[tableEnd] Returns .true. if end of table mark (;;) is encountered.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

45.3.14 ESMF_ConfigSetAttribute - Set a value

INTERFACE:

 subroutine ESMF_ConfigSetAttribute(config, <value argument>, &
 label, rc)

ARGUMENTS:

 type(ESMF_Config), intent(inout) :: config
 <value argument>, see below for supported values
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
 character(len=*), intent(in), optional :: label
 integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Sets a value in the config object.

Supported values for <value argument> are:

 integer(ESMF_KIND_I4), intent(in) :: value
The arguments are:

**config**  Already created ESMF_Config object.

<**value argument**>  Value to set.

[**label**]  Identifying attribute label.

[**rc**]  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 45.3.15  ESMF_ConfigValidate - Validate a Config object

**INTERFACE:**

```fortran
subroutine ESMF_ConfigValidate(config, &
    options, rc)
```

**ARGUMENTS:**

- `type(ESMF_Config), intent(inout) :: config`
- `character (len= * ), intent(in), optional :: options`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Checks whether a config object is valid.

The arguments are:

**config**  ESMF_Config object to be validated.

[**options**]  If none specified: simply check that the buffer is not full and the pointers are within range.  "unusedAttributes" - Report to the default logfile all attributes not retrieved via a call to ESMF_ConfigGetAttribute() or ESMF_ConfigGetChar(). The attribute name (label) will be logged via ESMF_LogErr with the WARNING log message type. For an array-valued attribute, retrieving at least one value via ESMF_ConfigGetAttribute() or ESMF_ConfigGetChar() constitutes being "used."

[**rc**]  Return code; equals ESMF_SUCCESS if there are no errors. Equals ESMF_RC_ATTR_UNUSED if any unused attributes are found with option "unusedAttributes" above.
46 Log Class

46.1 Description

The Log class consists of a variety of methods for writing error, warning, and informational messages to files. A default Log is created at ESMF initialization. Other Logs can be created later in the code by the user. Most Log methods take a Log as an optional argument and apply to the default Log when another Log is not specified. A set of standard return codes and associated messages are provided for error handling.

Log provides capabilities to store message entries in a buffer, which is flushed to a file, either when the buffer is full, or when the user calls an ESMF_LogFlush() method. Currently, the default is for the Log to flush after every ten entries. This can easily be changed by using the ESMF_LogSet() method and setting the maxElements property to another value. The ESMF_LogFlush() method is automatically called when the program exits by any means (program completion, halt on error, or when the Log is closed).

The user has the capability to abort the program on conditions such as an error or on a warning by using the ESMF_LogSet() method with the logmsgAbort argument. For example if the logmsgAbort array is set to (ESMF_LOGMSG_ERROR, ESMF_LOGMSG_WARNING), the program will stop on any and all warning or errors. When the logmsgAbort argument is set to ESMF_LOGMSG_ERROR, the program will only abort on errors. Lastly, the user can choose to never abort by using ESMF_LOGMSG_NONE; this is the default.

Log will automatically put the PET number into the Log. Also, the user can either specify ESMF_LOGKIND_SINGLE which writes all the entries to a single Log or ESMF_LOGKIND_MULTI which writes entries to multiple Logs according to the PET number. To distinguish Logs from each other when using ESMF_LOGKIND_MULTI, the PET number (in the format PETx. ) will be prepended to the file name where x is the PET number.

Opening multiple log files and writing log messages from all the processors may affect the application performance while running on a large number of processors. For that reason, ESMF_LOGKIND_NONE is provided to switch off the Log capability. All the Log methods have no effect in the ESMF_LOGKIND_NONE mode.

A tracing capability may be enabled by setting the trace flag by using the ESMF_LogSet() method. When tracing is enabled, calls to methods such as ESMF_LogFoundError, ESMF_LogFoundAllocError, and ESMF_LogFoundDeallocError are logged in the default log file. This can result in voluminous output. It is typically used only around areas of code which are being debugged.

Other options that are planned for Log are to adjust the verbosity of output, and to optionally write to stdout instead of file(s).

46.2 Constants

46.2.1 ESMF_LOGERR

The valid values are:

ESMF_LOGERR_PASSTHRU A named character constant, with a predefined generic error message, that can be used for the msg argument in any ESMF_Log routine. The message indicated by this named constant is “Passing error in return code.”
46.2.2 ESMF_LOGKIND

DESCRIPTION:
Specifies a single log file, multiple log files (one per PET), or no log files.

The type of this flag is:
\texttt{type(ESMF\_LogKind\_Flag)}

The valid values are:

\textbf{ESMF\_LOGKIND\_SINGLE} Use a single log file, combining messages from all of the PETs. Not supported on some platforms.

\textbf{ESMF\_LOGKIND\_MULTI} Use multiple log files — one per PET.

\textbf{ESMF\_LOGKIND\_NONE} Do not issue messages to a log file.

46.2.3 ESMF_LOGMSG

DESCRIPTION:

Specifies a message level

The type of this flag is:
\texttt{type(ESMF\_LogMsg\_Flag)}

The valid values are:

\textbf{ESMF\_LOGMSG\_INFO} Informational messages
\textbf{ESMF\_LOGMSG\_WARNING} Warning messages
\textbf{ESMF\_LOGMSG\_ERROR} Error messages
\textbf{ESMF\_LOGMSG\_TRACE} Trace messages

Valid predefined named array constant values are:

\textbf{ESMF\_LOGMSG\_ALL} All messages
\textbf{ESMF\_LOGMSG\_NONE} No messages
\textbf{ESMF\_LOGMSG\_NOTRACE} All messages EXCEPT trace messages

46.3 Use and Examples

By default \texttt{ESMF\_Initialize()} opens a default Log in \textbf{ESMF\_LOGKIND\_MULTI} mode. ESMF handles the initialization and finalization of the default Log so the user can immediately start using it. If additional Log objects are desired, they must be explicitly created or opened using \texttt{ESMF\_LogOpen()}.

\texttt{ESMF\_LogOpen()} requires a Log object and filename argument. Additionally, the user can specify single or multi Logs by setting the \texttt{logkindflag} property to \textbf{ESMF\_LOGKIND\_SINGLE} or \textbf{ESMF\_LOGKIND\_MULTI}. This is
useful as the PET numbers are automatically added to the Log entries. A single Log will put all entries, regardless of PET number, into a single log while a multi Log will create multiple Logs with the PET number prepended to the filename and all entries will be written to their corresponding Log by their PET number.

By default, the Log file is not truncated at the start of a new run; it just gets appended each time. Future functionality may include an option to either truncate or append to the Log file.

In all cases where a Log is opened, a Fortran unit number is assigned to a specific Log. A Log is assigned an unused unit number using the algorithm described in the ESMF_IOUnitGet() method.

The user can then set or get options on how the Log should be used with the ESMF_LogSet() and ESMF_LogGet() methods. These are partially implemented at this time.

Depending on how the options are set, ESMF_LogWrite() either writes user messages directly to a Log file or writes to a buffer that can be flushed when full or by using the ESMF_LogFlush() method. The default is to flush after every ten entries because maxElements is initialized to ten (which means the buffer reaches its full state after every ten writes and then flushes).

A message filtering option may be set with ESMF_LogSet() so that only selected message types are actually written to the log. One key use of this feature is to allow placing informational log write requests into the code for debugging or tracing. Then, when the informational entries are not needed, the messages at that level may be turned off — leaving only warning and error messages in the logs.

For every ESMF_LogWrite(), a time and date stamp is prepended to the Log entry. The time is given in microsecond precision. The user can call other methods to write to the Log. In every case, all methods eventually make a call implicitly to ESMF_LogWrite() even though the user may never explicitly call it.

When calling ESMF_LogWrite(), the user can supply an optional line, file and method. These arguments can be passed in explicitly or with the help of cpp macros. In the latter case, a define for an ESMF_FILENAME must be placed at the beginning of a file and a define for ESMF_METHOD must be placed at the beginning of each method. The user can then use the ESMF_CONTEXT cpp macro in place of line, file and method to insert the parameters into the method. The user does not have to specify line number as it is a value supplied by cpp.

An example of Log output is given below running with logkindflag property set to ESMF_LOGKIND_MULTI (default) using the default Log:

(Log file PET0.ESMF_LogFile)

20041105 163418.472210 INFO PET0 Running with ESMF Version 2.2.1

(Log file PET1.ESMF_LogFile)

20041105 163419.186153 ERROR PET1 ESMF_Field.F90 812 ESMF_FieldGet No Grid or Bad Grid attached to Field

The first entry shows date and time stamp. The time is given in microsecond precision. The next item shown is the type of message (INFO in this case). Next, the PET number is added. Lastly, the content is written.

The second entry shows something slightly different. In this case, we have an ERROR. The method name (ESMF_Field.F90) is automatically provided from the cpp macros as well as the line number (812). Then the content of the message is written.

When done writing messages, the default Log is closed by calling ESMF_LogFinalize() or ESMF_LogClose() for user created Logs. Both methods will release the assigned unit number.

! !PROGRAM: ESMF_LogErrEx - Log Error examples

1040
This program shows examples of Log Error writing.

```plaintext
#include "ESMF.h"

// Macros for cpp usage
#define ESMF_FILENAME "ESMF_LogErrEx.F90"
#define ESMF_METHOD "program ESMF_LogErrEx"
#include "ESMF_LogMacros.inc"

! ESMF Framework module
use ESMF
use ESMF_TestMod
implicit none

! return variables
integer :: rc1, rc2, rc3, rcToTest, allocRcToTest, result
type(ESMF_LOG) :: alog ! a log object that is not the default log
type(ESMF_LogKind_Flag) :: logkindflag
type(ESMF_Time) :: time
type(ESMF_VM) :: vm
integer, pointer :: intptr(:)

46.3.1 Default Log

This example shows how to use the default Log. This example does not use cpp macros but does use multi Logs. A separate Log will be created for each PET.

! Initialize ESMF to initialize the default Log
call ESMF_Initialize(vm=vm, defaultlogfilename="LogErrEx.Log", &
                    logkindflag=ESMF_LOGKIND_MULTI, rc=rc1)

! LogWrite
call ESMF_LogWrite("Log Write 2", ESMF_LOGMSG_INFO, rc=rc2)

! LogMsgSetError
call ESMF_LogSetError(ESMF_RC_OBJ_BAD, msg="Convergence failure", &
                      rcToReturn=rc2)

! LogMsgFoundError
call ESMF_TimeSet(time, calkindflag=ESMF_CALKIND_NOCALENDAR)
call ESMF_TimeSyncToRealTime(time, rc=rcToTest)
if (ESMF_LogFoundError(rcToTest, msg="getting wall clock time", &
                        rcToReturn=rc2)) then
    ! Error getting time. The previous call will have printed the error
```

1041
! already into the log file. Add any additional error handling here.
! (This call is expected to provoke an error from the Time Manager.)
endif

! LogMsgFoundAllocError
allocate(intptr(10), stat=allocRcToTest)
if (ESMF_LogFoundAllocError(allocRcToTest, msg="integer array", &
    rcToReturn=rc2)) then
    ! Error during allocation. The previous call will have logged already
    ! an error message into the log.
endif
deallocate(intptr)

46.3.2 User created Log

This example shows how to use a user created Log. This example uses cpp macros.

    ! Open a Log named "Testlog.txt" associated with alog.
call ESMF_LogOpen(alog, "TestLog.txt", rc=rc1)

%\\begin{verbatim}

! LogWrite
call ESMF_LogWrite("Log Write 2", ESMF_LOGMSG_INFO, &
    line=__LINE__, file=ESMF_FILENAME, &
    method=ESMF_METHOD, log=alog, rc=rc2)

! LogMsgSetError
call ESMF_LogSetError(ESMF_RC_OBJ_BAD, msg="Interpolation Failure", &
    line=__LINE__, file=ESMF_FILENAME, &
    method=ESMF_METHOD, rcToReturn=rc2, log=alog)

\\end{verbatim}

46.3.3 Get and Set

This example shows how to use Get and Set routines, on both the default Log and the user created Log from the
previous examples.

! This is an example showing a query of the default Log. Please note that
! no Log is passed in the argument list, so the default Log will be used.
call ESMF_LogGet(logkindflag=logkindflag, rc=rc3)

! This is an example setting a property of a Log that is not the default.
! It was opened in a previous example, and the handle for it must be
! passed in the argument list.
call ESMF_LogSet(log=alog, logmsgAbort=('/ESMF_LOGMSG_ERROR/'), rc=rc2)

! Close the user log.
call ESMF_LogClose(alog, rc=rc3)

! Finalize ESMF to close the default log
call ESMF_Finalize(rc=rc1)

46.4 Restrictions and Future Work

1. **Line, file and method are only available when using the C preprocessor** Message writing methods are expanded using the ESMF macro ESMF_CONTEXT that adds the predefined symbolic constants __LINE__ and __FILE__ (or the ESMF constant ESMF_FILENAME if defined) and the ESMF constant ESMF_METHOD to the argument list. Using these constants, we can associate a file name, line number and method name with the message. If the CPP preprocessor is not used, this expansion will not be done and hence the ESMF macro ESMF_CONTEXT can not be used, leaving the file name, line number and method out of the Log text.

2. **Get and set methods are partially implemented.** Currently, the ESMF_LogGet() and ESMF_LogSet() methods are partially implemented.

3. **Log only appends entries.** All writing to the Log is appended rather than overwriting the Log. Future enhancements include the option to either append to an existing Log or overwrite the existing Log.

4. **Avoiding conflicts with the default Log.** The private methods ESMF_LogInitialize() and ESMF_LogFinalize() are called during ESMF_Initialize() and ESMF_Finalize() respectively, so they do not need to be called if the default Log is used. If a new Log is required, ESMF_LogOpen() is used with a new Log object passed in so that there are no conflicts with the default Log.

5. **ESMF_LOGKIND_SINGLE does not work properly.** When the ESMF_LogKind_Flag is set to ESMF_LOGKIND_SINGLE, different system may behave differently. The log messages from some processors may be lost or overwritten by other processors. Users are advised not to use this mode. The MPI-based I/O will be implemented to fix the problem in the future release.

46.5 Design and Implementation Notes

1. The Log class was implemented in Fortran and uses the Fortran I/O libraries when the class methods are called from Fortran. The C/C++ Log methods use the Fortran I/O library by calling utility functions that are written in Fortran. These utility functions call the standard Fortran write, open and close functions. At initialization an ESMF_LOG is created. The ESMF_LOG stores information for a specific Log file. When working with more than one Log file, multiple ESMF_LOG’s are required (one ESMF_LOG for each Log file). For each Log, a handle is returned through the ESMF_LogInitialize method for the default log or ESMF_LogOpen for a user created log. The user can specify single or multi logs by setting the logkindflag property in the ESMF_LogInitialize or ESMF_Open method to ESMF_LOGKIND_SINGLE or ESMF_LOGKIND_MULTI. Similarly, the user can set the logkindflag property for the default Log with the ESMF_Initialize method call. The logkindflag is useful as
the PET numbers are automatically added to the log entries. A single log will put all entries, regardless of PET number, into a single log while a multi log will create multiple logs with the PET number prepended to the filename and all entries will be written to their corresponding log by their PET number.

The properties for a Log are set with the `ESMF_LogSet()` method and retrieved with the `ESMF_LogGet()` method.

Additionally, buffering is enabled. Buffering allows ESMF to manage output data streams in a desired way. Writing to the buffer is transparent to the user because all the Log entries are handled automatically by the `ESMF_LogWrite()` method. All the user has to do is specify the buffer size (the default is ten) by setting the `maxElements` property. Every time the `ESMF_LogWrite()` method is called, a LogEntry element is populated with the `ESMF_LogWrite()` information. When the buffer is full (i.e., when all the LogEntry elements are populated), the buffer will be flushed and all the contents will be written to file. If buffering is not needed, that is `maxElements=1` or `flushImmediately=ESMF_TRUE`, the `ESMF_LogWrite()` method will immediately write to the Log file(s).

### 46.6 Object Model

The following is a simplified UML diagram showing the structure of the Log class. See Appendix A, *A Brief Introduction to UML*, for a translation table that lists the symbols in the diagram and their meaning.

#### 46.7 Class API

#### 46.7.1 ESMF_LogAssignment(=) - Log assignment

**INTERFACE:**

```plaintext
interface assignment (=)
log1 = log2
```
ARGUMENTS:

```fortran
  type(ESMF_Log) :: log1
  type(ESMF_Log) :: log2
```

DESCRIPTION:

Assign `log1` as an alias to the same `ESMF_Log` object in memory as `log2`. If `log2` is invalid, then `log1` will be equally invalid after the assignment.

The arguments are:

- **log1** The `ESMF_Log` object on the left hand side of the assignment.
- **log2** The `ESMF_Log` object on the right hand side of the assignment.

---

### 46.7.2 ESMF_LogOperator(==) - Test if Log 1 is equivalent to Log 2

INTERFACE:

```fortran
  interface operator(==)
    if (log1 == log2) then ... endif
  end interface
  OR
  result = (log1 == log2)
```

RETURN VALUE:

```fortran
  logical :: result
```

ARGUMENTS:

```fortran
  type(ESMF_Log), intent(in) :: log1
  type(ESMF_Log), intent(in) :: log2
```

DESCRIPTION:

Overloads the `==` operator for the `ESMF_Log` class. Compare two logs for equality; return `.true.` if equal, `.false.` otherwise. Comparison is based on whether the objects are distinct, as with two newly created logs, or are simply aliases to the same log as would be the case when assignment was involved.

The arguments are:

- **log1** The `ESMF_Log` object on the left hand side of the equality operation.
- **log2** The `ESMF_Log` object on the right hand side of the equality operation.
46.7.3  ESMF_LogOperator(/=) - Test if Log 1 is not equivalent to Log 2

INTERFACE:

```fortran
interface operator(/=)
  if (log1 /= log2) then ... endif
OR
  result = (log1 /= log2)
end interface
```

RETURN VALUE:

```fortran
logical :: result
```

ARGUMENTS:

```fortran
  type(ESMF_Log), intent(in) :: log1
  type(ESMF_Log), intent(in) :: log2
```

DESCRIPTION:

Overloads the (/=) operator for the ESMF_Log class. Compare two logs for inequality; return .true. if equal, .false. otherwise. Comparison is based on whether the objects are distinct, as with two newly created logs, or are simply aliases to the same log as would be the case when assignment was involved.

The arguments are:

- **log1** The ESMF_Log object on the left hand side of the non-equality operation.
- **log2** The ESMF_Log object on the right hand side of the non-equality operation.

46.7.4  ESMF_LogClose - Close Log file(s)

INTERFACE:

```fortran
subroutine ESMF_LogClose(log, rc)
ARGUMENTS:
  type(ESMF_Log), intent(inout) :: log
  type(ESMF_KeywordEnforcer),optional::keywordEnforcer !must use keywords below
  integer,       intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

This routine closes the user log file(s) associated with log. If the log is not explicitly closed, it will be closed by ESMF_Finalize.

The arguments are:

log An ESMF_Log object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

46.7.5 ESMF_LogFlush - Flush the Log file(s)

INTERFACE:

subroutine ESMF_LogFlush(log, rc)

ARGUMENTS:

type(ESMF_KeywordEnforcer),optional::keywordEnforce !must use keywords below
type(ESMF_Log), intent(inout), optional :: log
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This subroutine flushes the file buffer associated with log.

The arguments are:

[log] An optional ESMF_Log object that can be used instead of the default Log.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

46.7.6 ESMF_LogFoundAllocError - Check Fortran allocation status error and write message

INTERFACE:
function ESMF_LogFoundAllocError(statusToCheck, &
    msg,line,file, &
    method,rcToReturn,log)

RETURN VALUE:

logical :: ESMF_LogFoundAllocError

ARGUMENTS:

integer, intent(in) :: statusToCheck
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len= * ), intent(in), optional :: msg
integer, intent(in), optional :: line
character(len= * ), intent(in), optional :: file
character(len= * ), intent(in), optional :: method
integer, intent(inout), optional :: rcToReturn
type(ESMF_Log), intent(inout), optional :: log

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This function returns .true. when statusToCheck indicates an allocation error, otherwise it returns .false.. The status value is typically returned from a Fortran ALLOCATE statement. If an error is indicated, a ESMF memory allocation error message will be written to the ESMF_Log along with a user added msg, line, file and method.

The arguments are:

statusToCheck  Fortran allocation status to check. Fortran specifies that a status of 0 (zero) indicates success.
[msg] User-provided message string.
[line] Integer source line number. Expected to be set by using the preprocessor __LINE__ macro.
[file] User-provided source file name.
[method] User-provided method string.
[rcToReturn] If specified, when the allocation status indicates an error, set the rcToReturn value to ESMF_RC_MEM. Otherwise, rcToReturn is not modified.
[log] An optional ESMF_Log object that can be used instead of the default Log.
46.7.7 ESMF_LogFoundDeallocError - Check Fortran deallocation status error and write message

INTERFACE:

```fortran
function ESMF_LogFoundDeallocError(statusToCheck, &
    msg, line, file, &
    method, rcToReturn, log)
RETURN VALUE:
logical :: ESMF_LogFoundDeallocError
ARGUMENTS:

integer, intent(in) :: statusToCheck
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
character(len= * ), intent(in), optional :: msg
integer, intent(in), optional :: line
character(len= * ), intent(in), optional :: file
character(len= * ), intent(in), optional :: method
integer, intent(inout), optional :: rcToReturn
```

```fortran
type(ESMF_Log), intent(inout), optional :: log
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This function returns `.true.` when `statusToCheck` indicates a deallocation error, otherwise it returns `.false.`. The status value is typically returned from a Fortran DEALLOCATE statement. If an error is indicated, an ESMF memory allocation error message will be written to the `ESMF_Log` along with a user added `msg`, `line`, `file` and `method`.

The arguments are:

- **statusToCheck**  Fortran deallocation status to check. Fortran specifies that a status of 0 (zero) indicates success.
- **msg** User-provided message string.
- **line** Integer source line number. Expected to be set by using the preprocessor `__LINE__` macro.
- **file** User-provided source file name.
- **method** User-provided method string.
- **rcToReturn** If specified, when the deallocation status indicates an error, set the `rcToReturn` value to `ESMF_RC_MEM`. Otherwise, `rcToReturn` is not modified.
- **log** An optional `ESMF_Log` object that can be used instead of the default Log.
46.7.8  ESMF_LogFoundError - Check ESMF return code for error and write message

INTERFACE:

    function ESMF_LogFoundError(rcToCheck, &
                          msg, line, file, method, &
                          rcToReturn, log)

RETURN VALUE:

    logical :: ESMF_LogFoundError

ARGUMENTS:

    integer,    intent(in),   optional :: rcToCheck
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    character(len= *), intent(in),   optional :: msg
    integer,    intent(in),   optional :: line
    character(len= *), intent(in),   optional :: file
    character(len= *), intent(in),   optional :: method
    integer,    intent(inout),   optional :: rcToReturn
    type(ESMF_Log), intent(inout),   optional :: log

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This function returns .true. when rcToCheck indicates an return code other than ESMF_SUCCESS, otherwise it returns .false.. If an error is indicated, a ESMF predefined error message will be written to the ESMF_Log along with a user added msg,line,file and method.

The arguments are:

[rcToCheck]  Return code to check. Default is ESMF_SUCCESS.
[msg]  User-provided message string.
[line]  Integer source line number. Expected to be set by using the preprocessor __LINE__ macro.
[file]  User-provided source file name.
[method]  User-provided method string.
[rcToReturn]  If specified, when rcToCheck indicates an error, set the rcToReturn to the value of rcToCheck. Otherwise, rcToReturn is not modified. This is not the return code for this function; it allows the calling code to do an assignment of the error code at the same time it is testing the value.
[log]  An optional ESMF_Log object that can be used instead of the default Log.
46.7.9 ESMF_LogOpen - Open Log file(s)

INTERFACE:

    subroutine ESMF_LogOpen(log, filename, logkindflag, rc)

ARGUMENTS:

    type(ESMF_Log), intent(inout) :: log
    character(len=*) , intent(in) :: filename
    type(ESMF_LogKind_Flag), intent(in), optional :: logkindflag
    integer, intent(out), optional :: rc

DESCRIPTION:

This routine opens a file named filename and associates it with the ESMF_Log. If the incoming log is already a
valid Log object, no new Log is opened and the Log argument remains unchanged.

The arguments are:

log   An ESMF_Log object.
filename Name of log file to be opened.
[logkindflag] Set the logkindflag. See section 46.2.2 for a list of valid options. If not specified, defaults to
ESMF_LOGKIND_MULTI.
[rc]   Return code; equals ESMF_SUCCESS if there are no errors.

46.7.10 ESMF_LogSet - Set Log parameters

INTERFACE:

    subroutine ESMF_LogSet(log, flush, &
                           logmsgAbort, maxElements, logmsgList, &
                           errorMask, trace, rc)

ARGUMENTS:

    type(ESMF_Log), intent(inout), optional :: log
    logical, intent(in), optional :: flush
    type(ESMF_LogMsg_Flag), intent(in), optional :: logmsgAbort(:)
    integer, intent(in), optional :: maxElements
    type(ESMF_LogMsg_Flag), intent(in), optional :: logmsgList(:)
    integer, intent(in), optional :: errorMask(:)
    logical, intent(in), optional :: trace
    integer, intent(out), optional :: rc
DESCRIPTION:

This subroutine sets the properties for the Log object.

The arguments are:

[log] An optional ESMF_Log object. The default is to use the default log that was opened at ESMF_Initialize time.

[flush] If set to .true., flush log messages immediately, rather than buffering them. Default is to flush after maxElements messages.

[logmsgAbort] Sets the condition on which ESMF aborts. The array can contain any combination of ESMF_LOGMSG named constants. These named constants are described in section 46.2.3. Default is to always continue processing.

[maxElements] Maximum number of elements in the Log buffer before flushing occurs. Default is to flush when 10 messages have been accumulated.

[logmsgList] An array of message types that will be logged. Log write requests not matching the list will be ignored. If an empty array is provided, no messages will be logged. See section 46.2.3 for a list of valid message types. By default, all non-trace messages will be logged.

[errorMask] List of error codes that will not be logged as errors. Default is to log all error codes.

[trace] If set to .true., calls such as ESMF_LogFoundError(), ESMF_LogFoundAllocError(), and ESMF_LogFoundDeallocError() will be logged in the default log files. This option is intended to be used as a tool for debugging and program flow tracing within the ESMF library. Voluminous output may appear in the log, with a consequent slowdown in performance. Therefore, it is recommended that this option only be enabled before a problematic call to a ESMF method, and disabled afterwards. Default is to not trace these calls.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

46.7.11 ESMF_LogSetError - Set ESMF return code for error and write msg

INTERFACE:

```fortran
subroutine ESMF_LogSetError(rcToCheck, &
  msg, line, file, method, &
  rcToReturn, log)
```

ARGUMENTS:

- integer, intent(in) :: rcToCheck
- character(len=*) , intent(in), optional :: msg
- integer, intent(in), optional :: line
- character(len=*) , intent(in), optional :: file
- character(len=*) , intent(in), optional :: method
- integer, intent(out), optional :: rcToReturn
- type(ESMF_Log), intent(inout), optional :: log

---

1052
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This subroutine sets the rcToReturn value to rcToCheck if rcToReturn is present and writes this error code to the ESMF_Log if an error is generated. A predefined error message will added to the ESMF_Log along with a user added msg, line, file and method.

The arguments are:

rcToCheck  rc value for set
[msg] User-provided message string.
[line] Integer source line number. Expected to be set by using the preprocessor macro __LINE__ macro.
[file] User-provided source file name.
[method] User-provided method string.
[rcToReturn] If specified, copy the rcToCheck value to rcToReturn. This is not the return code for this function; it allows the calling code to do an assignment of the error code at the same time it is testing the value.
[log] An optional ESMF_Log object that can be used instead of the default Log.

46.7.12 ESMF_LogWrite - Write to Log file(s)

INTERFACE:

recursive subroutine ESMF_LogWrite(msg, logmsgFlag, &
  logmsgList, & ! DEPRECATED ARGUMENT
  line, file, method, log, rc)

ARGUMENTS:

character(len=*) , intent(in)   :: msg
  type(ESMF_LogMsg_Flag), intent(in), optional  :: logmsgFlag
  type(ESMF_LogMsg_Flag), intent(in), optional:: logmsgList ! DEPRECATED ARG
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: line
  character(len=*) , intent(in), optional :: file
  character(len=*) , intent(in), optional :: method
  type(ESMF_Log), intent(inout),optional :: log
  integer, intent(out), optional :: rc

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.2.0rp1 Added argument logmsgFlag. Started to deprecate argument logmsgList. This corrects inconsistent use of the List suffix on the argument name. In ESMF this suffix indicates one-dimensional array arguments.

DESCRIPTION:

This subroutine writes to the file associated with an ESMF_Log. A message is passed in along with the logmsgFlag, line, file and method. If the write to the ESMF_Log is successful, the function will return a logical true. This function is the base function used by all the other ESMF_Log writing methods.

The arguments are:

**msg** User-provided message string.

**logmsgFlag** The type of message. See Section 46.2.3 for possible values.

**logmsgList** DEPRECATED ARGUMENT! Please use the argument logmsgFlag instead.

**[line]** Integer source line number. Expected to be set by using the preprocessor macro __LINE__ macro.

**[file]** User-provided source file name.

**[method]** User-provided method string.

**[log]** An optional ESMF_Log object that can be used instead of the default Log.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

47 DELayout Class

47.1 Description

The DELayout class provides an additional layer of abstraction on top of the Virtual Machine (VM) layer. DELayout does this by introducing DEs (Decomposition Elements) as logical resource units. The DELayout object keeps track of the relationship between its DEs and the resources of the associated VM object.

The relationship between DEs and VM resources (PETs (Persistent Execution Threads) and VASs (Virtual Address Spaces)) contained in a DELayout object is defined during its creation and cannot be changed thereafter. There are, however, a number of hint and specification arguments that can be used to shape the DELayout during its creation.

Contrary to the number of PETs and VASs contained in a VM object, which are fixed by the available resources, the number of DEs contained in a DELayout can be chosen freely to best match the computational problem or other design criteria. Creating a DELayout with less DEs than there are PETs in the associated VM object can be used to share resources between decomposed objects within an ESMF component. Creating a DELayout with more DEs than there are PETs in the associated VM object can be used to evenly partition the computation over the available resources.
The simplest case, however, is where the DELayout contains the same number of DEs as there are PETs in the associated VM context. In this case the DELayout may be used to re-label the hardware and operating system resources held by the VM. For instance, it is possible to order the resources so that specific DEs have best available communication paths. The DELayout will map the DEs to the PETs of the VM according to the resource details provided by the VM instance.

Furthermore, general DE to PET mapping can be used to offer computational resources with finer granularity than the VM does. The DELayout can be queried for computational and communication capacities of DEs and DE pairs, respectively. This information can be used to best utilize the DE resources when partitioning the computational problem. In combination with other ESMF classes, general DE to PET mapping can be used to realize cache blocking, communication hiding and dynamic load balancing.

Finally, the DELayout layer offers primitives that allow a work queue style dynamic load balancing between DEs.

### 47.2 Constants

#### 47.2.1 ESMF_PIN

**DESCRIPTION:**
Specifies which VM resource DEs are pinned to - i.e. PETs or VASs.

The type of this flag is:

type (ESMF_Pin_Flag)

The valid values are:

- **ESMF_PIN_DE_TO_PET** Pin DEs against PETs. This means that even if a group of PETs in the VM are sharing a common virtual address space (VAS), DEs cannot be shared between PETs, but must be serviced by the specific PET they are pinned to.

- **ESMF_PIN_DE_TO_VAS** Pin DEs against VASs. DEs may be serviced by any PET that is executing within the virtual address space (VAS) the DE is pinned to.

#### 47.2.2 ESMF_SERVICEREPLY

**DESCRIPTION:**
Reply when a PET offers to service a DE.

The type of this flag is:

type (ESMF_ServiceReply_Flag)

The valid values are:

- **ESMF_SERVICEREPLY_ACCEPT** The service offer has been accepted. The PET is expected to service the DE.

- **ESMF_SERVICEREPLY_DENY** The service offer has been denied. The PET is expected to not service the DE.

### 47.3 Use and Examples

The following examples demonstrate how to create, use and destroy DELayout objects.
47.3.1 Default DELayout

Without specifying any of the optional parameters the created ESMF_DELayout defaults into having as many DEs as there are PETs in the associated VM object. Consequently the resulting DELayout describes a simple 1-to-1 DE to PET mapping.

```c
delayout = ESMF_DELayoutCreate(rc=rc)
```

The default DE to PET mapping is simply:

- \( \text{DE 0} \rightarrow \text{PET 0} \)
- \( \text{DE 1} \rightarrow \text{PET 1} \)
- ...

DELayout objects that are not used any longer should be destroyed.

```c
call ESMF_DELayoutDestroy(delayout, rc=rc)
```

The optional \( \text{vm} \) argument can be provided to DELayoutCreate() to lower the method’s overhead by the amount it takes to determine the current VM.

```c
delayout = ESMF_DELayoutCreate(vm=vm, rc=rc)
```

By default all PETs of the associated VM will be considered. However, if the optional argument \( \text{petList} \) is present DEs will only be mapped against the PETs contained in the list. When the following example is executed on four PETs it creates a DELayout with four DEs by default that are mapped to the provided PETs in their given order. It is erroneous to specify PETs that are not part of the VM context on which the DELayout is defined.

```c
delayout = ESMF_DELayoutCreate(petList=\((i,i=\text{petCount}-1,1,-1)/\), rc=rc)
```

Once the end of the petList has been reached the DE to PET mapping continues from the beginning of the list. For a 4 PET VM the above created DELayout will end up with the following DE to PET mapping:

- \( \text{DE 0} \rightarrow \text{PET 3} \)
- \( \text{DE 1} \rightarrow \text{PET 2} \)
- \( \text{DE 2} \rightarrow \text{PET 1} \)
- \( \text{DE 2} \rightarrow \text{PET 3} \)

47.3.2 DELayout with specified number of DEs

The \( \text{deCount} \) argument can be used to specify the number of DEs. In this example a DELayout is created that contains four times as many DEs as there are PETs in the VM.
Cyclic DE to PET mapping is the default. For 4 PETs this means:

- DE 0, 4, 8, 12 -> PET 0
- DE 1, 5, 9, 13 -> PET 1
- DE 2, 6, 10, 14 -> PET 2
- DE 3, 7, 11, 15 -> PET 3

The default DE to PET mapping can be overridden by providing the `deGrouping` argument. This argument provides a positive integer group number for each DE in the DELayout. All of the DEs of a group will be mapped against the same PET. The actual group index is arbitrary (but must be positive) and its value is of no consequence.

```
delayout = ESMF_DELayoutCreate(deCount=4*petCount, &
   deGrouping=(/(i/4,i=0,4*petCount-1)/), rc=rc)
```

This will achieve blocked DE to PET mapping. For 4 PETs this means:

- DE 0, 1, 2, 3 -> PET 0
- DE 4, 5, 6, 7 -> PET 1
- DE 8, 9, 10, 11 -> PET 2
- DE 12, 13, 14, 15 -> PET 3

### 47.3.3 DELayout with computational and communication weights

The quality of the partitioning expressed by the DE to PET mapping depends on the amount and quality of information provided during DELayout creation. In the following example the `compWeights` argument is used to specify relative computational weights for all DEs and communication weights for DE pairs are provided by the `commWeights` argument. The example assumes four DEs.

```
allocate(compWeights(4))
allocate(commWeights(4, 4))
! setup compWeights and commWeights according to computational problem
delayout = ESMF_DELayoutCreate(deCount=4, compWeights=compWeights, &
   commWeights=commWeights, rc=rc)
deallocate(compWeights, commWeights)
```

The resulting DE to PET mapping depends on the specifics of the VM object and the provided compWeights and commWeights arrays.

### 47.3.4 DELayout from petMap

Full control over the DE to PET mapping is provided via the `petMap` argument. This example maps the DEs to PETs in reverse order. In the 4-PET case this will result in the following mapping:
DE 0 -> PET 3
DE 1 -> PET 2
DE 2 -> PET 1
DE 3 -> PET 0

delayout = ESMF_DELayoutCreate(petMap=/(i,i=petCount-1,0,-1)/, rc=rc)

47.3.5 DELayout from petMap with multiple DEs per PET

The petMap argument gives full control over DE to PET mapping. The following example run on 4 or more PETs maps DEs to PETs according to the following table:

DE 0 -> PET 3
DE 1 -> PET 3
DE 2 -> PET 1
DE 3 -> PET 0
DE 4 -> PET 2
DE 5 -> PET 1
DE 6 -> PET 3
DE 7 -> PET 1

delayout = ESMF_DELayoutCreate(petMap=(/3, 3, 1, 0, 2, 1, 3, 1/), rc=rc)

47.3.6 Working with a DELayout - simple 1-to-1 DE-to-PET mapping

The simplest case is a DELayout where there is exactly one DE for every PET. Of course this implies that the number of DEs equals the number of PETs. This special 1-to-1 DE-to-PET mapping is very common and many applications assume it. The following example shows how a DELayout can be queried about its mapping.

First a default DELayout is created where the number of DEs equals the number of PETs, and are associated 1-to-1.

delayout = ESMF_DELayoutCreate(rc=rc)

Next the DELayout is queried for the oneToOneFlag, and the user code makes a decision based on its value.

call ESMF_DELayoutGet(delayout, oneToOneFlag=oneToOneFlag, rc=rc)
if (rc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
if (.not. oneToOneFlag) then
   ! handle the unexpected case of not dealing with a 1-to-1 mapping
else

1-to-1 mapping is guaranteed in this branch and the following code can work under the simplifying assumption that every PET holds exactly one DE:
allocate(localDeToDeMap(1))
call ESMF_DELayoutGet(delayout, localDeToDeMap=localDeToDeMap, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
myDe = localDeToDeMap(1)
deallocate(localDeToDeMap)
if (finalrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)
endif

47.3.7 Working with a DELayout - general DE-to-PET mapping

In general a DELayout may map any number (including zero) DEs against a single PET. The exact situation can be detected by querying the DELayout for the oneToOneFlag. If this flag comes back as .true. then the DELayout maps exactly one DE against each PET, but if it comes back as .false. the DELayout describes a more general DE-to-PET layout. The following example shows how code can be be written to work for a general DELayout.

First a DELayout is created with two more DEs than there are PETs. The DELayout will consequently map some DEs to the same PET.

delayout = ESMF_DELayoutCreate(deCount=petCount+2, rc=rc)

The first piece of information needed on each PET is the localDeCount. This number may be different on each PET and indicates how many DEs are mapped against the local PET.

call ESMF_DELayoutGet(delayout, localDeCount=localDeCount, rc=rc)

The DELayout can further be queried for a list of DEs that are held by the local PET. This information is provided by the localDeToDeMap argument. In ESMF a localDe is an index that enumerates the DEs that are associated with the local PET. In many cases the exact bounds of the localDe index range, e.g. [0...localDeCount − 1], or [1...localDeCount] does not matter, since it only affects how user code indexes into variables the user allocated, and therefore set the specific bounds. However, there are a few Array and Field level calls that take localDe input arguments. In all those cases where the localDe index variable is passed into an ESMF call as an input argument, it must be defined with a range starting at zero, i.e. [0...localDeCount − 1].

For consistency with Array and Field, the following code uses a [0...localDeCount − 1] range for the localDe index variable, although it is not strictly necessary here:

allocate(localDeToDeMap(0:localDeCount-1))
call ESMF_DELayoutGet(delayout, localDeToDeMap=localDeToDeMap, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
do localDe=0, localDeCount-1
   workDe = localDeToDeMap(localDe)
   ! print *, "I am PET", localPET, " and I am working on DE ", workDe
endo
deallocate(localDeToDeMap)
if (finalrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

47.3.8 Work queue dynamic load balancing

The DELayout API includes two calls that can be used to easily implement work queue dynamic load balancing. The work load is broken up into DEs (more than there are PETs) and processed by the PETs. Load balancing is only
possible for ESMF multi-threaded VMs and requires that DEs are pinned to VASs instead of the PETs (default). The following example will run for any VM and DELayout, however, load balancing will only occur under the mentioned conditions.

delayout = ESMF_DELLayoutCreate(deCount=petCount+2, &
    pinflag=ESMF_PIN_DE_TO_VAS, rc=rc)

call ESMF_DELLayoutGet(delayout, vasLocalDeCount=localDeCount, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
allocate(localDeToDeMap(localDeCount))
call ESMF_DELLayoutGet(delayout, vasLocalDeToDeMap=localDeToDeMap, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
do i=1, localDeCount
    workDe = localDeToDeMap(i)
    print *, "I am PET", localPET, &
        " and I am offering service for DE ", workDe
    reply = ESMF_DELLayoutServiceOffer(delayout, de=workDe, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
if (reply == ESMF_SERVICEREPLY_ACCEPT) then
    ! process work associated with workDe
    print *, "I am PET", localPET, ", service offer for DE ", workDe, &
        " was accepted."
    call ESMF_DELLayoutServiceComplete(delayout, de=workDe, rc=rc)
if (rc /= ESMF_SUCCESS) finalrc=rc
enddo
deallocate(localDeToDeMap)
if (finalrc /= ESMF_SUCCESS) call ESMF_Finalize(endflag=ESMF_END_ABORT)

47.4 Restrictions and Future Work

47.5 Design and Implementation Notes

The DELayout class is a light weight object. It stores the DE to PET and VAS mapping for all DEs within all PET instances and a list of local DEs for each PET instance. The DELayout does not store the computational and communication weights optionally provided as arguments to the create method. These hints are only used during create while they are available in user owned arrays.

47.6 Class API

47.6.1 ESMF_DELLayoutAssignment(=) - DELayout assignment

INTERFACE:

    interface assignment(=)
    delayout1 = delayout2

ARGUMENTS:
type (ESMF_DELayout) :: delayout1
type (ESMF_DELayout) :: delayout2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Assign delayout1 as an alias to the same ESMF DELayout object in memory as delayout2. If delayout2 is invalid, then delayout1 will be equally invalid after the assignment.

The arguments are:

- \texttt{delayout1} The \texttt{ESMF\_DELayout} object on the left hand side of the assignment.
- \texttt{delayout2} The \texttt{ESMF\_DELayout} object on the right hand side of the assignment.

### 47.6.2 ESMF\_DELayoutOperator(==) - DELayout equality operator

INTERFACE:

\begin{verbatim}
interface operator(==)
  if (delayout1 == delayout2) then ... endif
  result = (delayout1 == delayout2)
end interface
\end{verbatim}

RETURN VALUE:

logical :: result

ARGUMENTS:

- type (ESMF\_DELayout), intent(in) :: delayout1
- type (ESMF\_DELayout), intent(in) :: delayout2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether delayout1 and delayout2 are valid aliases to the same ESMF DELayout object in memory. For a more general comparison of two ESMF DELayouts, going beyond the simple alias test, the \texttt{ESMF\_DELayoutMatch()} function (not yet implemented) must be used.

The arguments are:
**delayout1** The ESMF_DELayout object on the left hand side of the equality operation.

**delayout2** The ESMF_DELayout object on the right hand side of the equality operation.

### 47.6.3 ESMF_DELayoutOperator( /= ) - DELayout not equal operator

**INTERFACE:**

```fortran
interface operator(/=)
    if (delayout1 /= delayout2) then ... endif
    OR
    result = (delayout1 /= delayout2)
end interface
```

**RETURN VALUE:**

```fortran
logical :: result
```

**ARGUMENTS:**

```fortran
  type(ESMF_DELayout), intent(in) :: delayout1
  type(ESMF_DELayout), intent(in) :: delayout2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Test whether delayout1 and delayout2 are not valid aliases to the same ESMF DELayout object in memory. For a more general comparison of two ESMF DELayouts, going beyond the simple alias test, the ESMF_DELayoutMatch() function (not yet implemented) must be used.

The arguments are:

**delayout1** The ESMF_DELayout object on the left hand side of the non-equality operation.

**delayout2** The ESMF_DELayout object on the right hand side of the non-equality operation.

### 47.6.4 ESMF_DELayoutCreate - Create DELayout object

**INTERFACE:**
Private name; call using ESMF_DELayoutCreate()

function ESMF_DELayoutCreateDefault(deCount, deGrouping, &
  pinflag, petList, vm, rc)

RETURN VALUE:

type(ESMF_DELayout) :: ESMF_DELayoutCreateDefault

ARGUMENTS:

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(in), optional :: deCount
  integer, target, intent(in), optional :: deGrouping(:)
  type(ESMF_Pin_Flag), intent(in), optional :: pinflag
  integer, target, intent(in), optional :: petList(:)
  type(ESMF_VM), intent(in), optional :: vm
  integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DELayout object on the basis of optionally provided restrictions. By default a DELayout with deCount equal to petCount will be created, each DE mapped to a single PET. However, the number of DEs as well grouping of DEs and PETs can be specified via the optional arguments.

The arguments are:

[deCount] Number of DEs to be provided by the created DELayout. By default the number of DEs equals the number of PETs in the associated VM context. Specifying a deCount smaller than the number of PETs will result in unassociated PETs. This may be used to share VM resources between DELayouts within the same ESMF component. Specifying a deCount greater than the number of PETs will result in multiple DE to PET mapping.

[deGrouping] This optional argument must be of size deCount. Its content assigns a DE group index to each DE of the DELayout. A group index of -1 indicates that the associated DE isn’t member of any particular group. The significance of DE groups is that all the DEs belonging to a certain group will be mapped against the same PET. This does not, however, mean that DEs belonging to different DE groups must be mapped to different PETs.

[pinflag] This flag specifies which type of resource DEs are pinned to. The default is to pin DEs to PETs. Alternatively it is also possible to pin DEs to VASs. See section 47.2.1 for a list of valid pinning options.

[petList] List specifying PETs to be used by this DELayout. This can be used to control the PET overlap between DELayouts within the same ESMF component. It is erroneous to specify PETs that are not within the provided VM context. The default is to include all the PETs of the VM.

[vm] If present, the DELayout object is created on the specified ESMF_VM object. The default is to create on the VM of the current context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
47.6.5 ESMF_DELayoutCreate - Create DELayout from petMap

INTERFACE:

! Private name; call using ESMF_DELayoutCreate()
function ESMF_DELayoutCreateFromPetMap(petMap, pinflag, &
   vm, rc)

RETURN VALUE:

   type(ESMF_DELayout) :: ESMF_DELayoutCreateFromPetMap

ARGUMENTS:

   integer, intent(in) :: petMap(:)
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_Pin_Flag), intent(in), optional :: pinflag
   type(ESMF_VM), intent(in), optional :: vm
   integer, intent(out), optional :: rc

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Create an ESMF_DELayout with exactly specified DE to PET mapping.

This ESMF method must be called in unison by all PETs of the VM. Calling this method from a PET not part of the VM or not calling it from a PET that is part of the VM will result in undefined behavior. ESMF does not guard against violation of the unison requirement. The call is not collective, there is no communication between PETs.

The arguments are:

petMap List specifying the DE-to-PET mapping. The list elements correspond to DE 0, 1, 2, ... and map against the specified PET of the VM context. The size of the petMap argument determines the number of DEs in the created DELayout. It is erroneous to specify a PET identifier that lies outside the VM context.

[pinflag] This flag specifies which type of resource DEs are pinned to. The default is to pin DEs to PETs. Alternatively it is also possible to pin DEs to VASs. See section 47.2.1 for a list of valid pinning options.

[vm] If present, the DELayout object is created on the specified ESMF_VM object. The default is to create on the VM of the current context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
47.6.6 ESMF_DELayoutDestroy - Release resources associated with DELayout object

INTERFACE:

subroutine ESMF_DELayoutDestroy(delayout, rc)

ARGUMENTS:

type(ESMF_DELayout), intent(inout) :: delayout
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Destroy an ESMF_DELayout object.

The arguments are:

delayout ESMF_DELayout object to be destroyed.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

47.6.7 ESMF_DELayoutGet - Get object-wide DELayout information

INTERFACE:

subroutine ESMF_DELayoutGet(delayout, vm, deCount, petMap, &
vasMap, oneToOneFlag, pinflag, localDeCount, localDeToDeMap, &
localDeList, & ! DEPRECATED ARGUMENT
vasLocalDeCount, vasLocalDeToDeMap, &
vasLocalDeList, & ! DEPRECATED ARGUMENT
rc)

ARGUMENTS:

type(ESMF_DELayout), intent(in) :: delayout
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_VM), intent(out), optional :: vm
integer, intent(out), optional :: deCount
integer, target, intent(out), optional :: petMap(:)
integer, target, intent(out), optional :: vasMap(:)
logical, intent(out), optional :: oneToOneFlag
type (ESMF_Pin_Flag),      intent(out), optional :: pinflag
integer,                  intent(out), optional :: localDeCount
integer, target,          intent(out), optional :: localDeToDeMap(:)
integer, target, intent(out), optional :: localDeList(:)!DEPRECATED ARG
integer,                  intent(out), optional :: vasLocalDeCount
integer, target,          intent(out), optional :: vasLocalDeToDeMap(:)
integer, target, intent(out), optional :: vasLocalDeList(:)!DEPRECATED ARG
integer,                  intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

- This interface was modified since ESMF version 5.2.0r. The fact that code using this interface compiles with the current ESMF version does not guarantee that it compiles with previous versions of this interface. If user code compatibility with version 5.2.0r is desired then care must be taken to limit the use of this interface to features that were available in the 5.2.0r release.

Changes made after the 5.2.0r release:

5.2.0rp1 Added arguments localDeToDeMap and vasLocalDeToDeMap. Started to deprecate arguments localDeList and vasLocalDeList. The new argument names correctly use the Map suffix and better describe the returned information. This was pointed out by user request.

DESCRIPTION:

Access to DELayout information.

The arguments are:

delayout Queried ESMF_DELayout object.
[vm] The ESMF_VM object on which delayout is defined.
[deCount] The total number of DEs in the DELayout.
[petMap] List of PETs against which the DEs are mapped. The petMap argument must at least be of size deCount.
[vasMap] List of VASs against which the DEs are mapped. The vasMap argument must at least be of size deCount.
[oneToOneFlag] A value of .TRUE. indicates that delayout maps each DE to a single PET, and each PET maps to a single DE. All other layouts return a value of .FALSE..
[pinflag] The type of DE pinning. See section 47.2.1 for a list of valid pinning options.
[localDeCount] The number of DEs in the DELayout associated with the local PET.
[localDeToDeMap] Mapping between localDe indices and the (global) DEs associated with the local PET. The localDe index variables are discussed in sections 47.3.7 and 27.2.5. The provided actual argument must be of size localDeCount.
[localDeList] DEPRECATED ARGUMENT! Please use the argument localDeToDeMap instead.
[vasLocalDeCount] The number of DEs in the DELayout associated with the local VAS.
[vasLocalDeToDeMap] Mapping between localDe indices and the (global) DEs associated with the local VAS. The localDe index variables are discussed in sections 47.3.7 and 27.2.5. The provided actual argument must be of size localDeCount.
47.6.8 ESMF_DELayoutPrint - Print DELayout information

INTERFACE:

```
subroutine ESMF_DELayoutPrint(delayout, rc)
ARGUMENTS:

  type(ESMF_DELayout), intent(in) :: delayout
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Prints internal information about the specified ESMF_DELayout object to stdout.

The arguments are:

**delayout** Specified ESMF_DELayout object.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

47.6.9 ESMF_DELayoutServiceComplete - Close service window

INTERFACE:

```
recursive subroutine ESMF_DELayoutServiceComplete(delayout, de, rc)
ARGUMENTS:

  type(ESMF_DELayout), intent(in) :: delayout
  integer, intent(in) :: de
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

[vasLocalDeList] DEPRECATED ARGUMENT! Please use the argument vasLocalDeToDeMap instead.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

The PET who’s service offer was accepted for `de` must use `ESMF_DELayoutServiceComplete` to close the service window.

The arguments are:

- `delayout` Specified `ESMF_DELayout` object.
- `de` DE for which to close service window.
- `[rc]` Return code; equals `ESMF_SUCCESS` if there are no errors.

47.6.10 `ESMF_DELayoutServiceOffer` - Offer service for a DE in `DELayout`

INTERFACE:

```fortran
recursive function ESMF_DELayoutServiceOffer(delayout, de, rc)
```

RETURN VALUE:

```fortran
type(ESMF_ServiceReply_Flag) :: ESMF_DELayoutServiceOffer
```

ARGUMENTS:

```fortran
type(ESMF_DELayout), intent(in) :: delayout
integer, intent(in) :: de
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Offer service for a DE in the `ESMF_DELayout` object. This call together with `ESMF_DELayoutServiceComplete()` provides the synchronization primitives between the PETs of an ESMF multi-threaded VM necessary for dynamic load balancing via a work queue approach.
The calling PET will either receive ESMF_Servicereply_accept if the service offer has been accepted by DELayout or ESMF_Servicereply_deny if the service offer was denied. The service offer paradigm is different from a simple mutex approach in that the DELayout keeps track of the number of service offers issued for each DE by each PET and accepts only one PET’s offer for each offer increment. This requires that all PETs use ESMF_DELayoutServiceOffer() in unison. See section 47.2.2 for the potential return values.

The arguments are:

**delayout** Specified ESMF_DELayout object.

**de** DE for which service is offered by the calling PET.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 47.6.11 ESMF_DELayoutValidate - Validate DELayout internals

**INTERFACE:**

```latex
subroutine ESMF_DELayoutValidate(delayout, rc)
```

**ARGUMENTS:**

```latex
type(ESMF_DELayout), intent(in) :: delayout
''
integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Validates that the `delayout` is internally consistent. The method returns an error code if problems are found.

The arguments are:

**delayout** Specified ESMF_DELayout object.

**[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

### 48 VM Class

#### 48.1 Description

The ESMF VM (Virtual Machine) class is a generic representation of hardware and system software resources. There is exactly one VM object per ESMF Component, providing the execution environment for the Component code. The
VM class handles all resource management tasks for the Component class and provides a description of the underlying configuration of the compute resources used by a Component.

In addition to resource description and management, the VM class offers the lowest level of ESMF communication methods. The VM communication calls are very similar to MPI. Data references in VM communication calls must be provided as raw, language specific, one-dimensional, contiguous data arrays. The similarity between VM and MPI communication calls is striking and there are many equivalent point-to-point and collective communication calls. However, unlike MPI, the VM communication calls support communication between threaded PETs in a completely transparent fashion.

Many ESMF applications do not interact with the VM class directly very much. The resource management aspect is wrapped completely transparent into the ESMF Component concept. Often the only reason that user code queries a Component object for the associated VM object is to inquire about resource information, such as the localPet or the petCount. Further, for most applications the use of higher level communication APIs, such as provided by Array and Field, are much more convenient than using the low level VM communication calls.

The basic elements of a VM are called PETs, which stands for Persistent Execution Threads. These are equivalent to OS threads with a lifetime of at least that of the associated component. All VM functionality is expressed in terms of PETs. In the simplest, and most common case, a PET is equivalent to an MPI process. However, ESMF also supports multi-threading, where multiple PETs run as Pthreads inside the same virtual address space (VAS).

The resource management functions of the VM class become visible when a component, or the driver code, creates sub-components. Section 15.4.5 discusses this aspect from the Superstructure perspective and provides links to the relevant Component examples in the documentation.

There are two parts to resource management, the parent and the child. When the parent component creates a child component, the parent VM object provides the resources on which the child is created with ESMF_GridCompCreate() or ESMF_CplCompCreate(). The optional petList argument to these calls limits the resources that the parent gives to a specific child. The child component, may specify - during its optional ESMF_<Grid/Cpl>CompSetVM() method - how it wants to arrange the inherited resources in its own VM. After this, all standard ESMF methods of the Component, including ESMF_<Grid/Cpl>CompSetServices(), will execute in the child VM. Notice that the ESMF_<Grid/Cpl>CompSetVM() routine, although part of the child Component, must execute before the child VM has been started up. It runs in the parent VM context. The child VM is created and started up just before the user-written set services routine, specified as an argument to ESMF_<Grid/Cpl>CompSetServices(), is entered.

### 48.2 Use and Examples

The concept of the ESMF Virtual Machine (VM) is so fundamental to the framework that every ESMF application uses it. However, for many user applications the VM class is transparently hidden behind the ESMF Component concept and higher data classes (e.g. Array, Field). The interaction between user code and VM is often only indirect. The following examples provide an overview of where the VM class can come into play in user code.

#### 48.2.1 Global VM

This complete example program demonstrates the simplest ESMF application, consisting of only a main program without any Components. The global VM, which is automatically created during the ESMF_Initialize() call, is obtained using two different methods. First the global VM will be returned by ESMF_Initialize() if the optional vm argument is specified. The example uses the VM object obtained this way to call the VM print method. Second, the global VM can be obtained anywhere in the user application using the ESMF_VMGetGlobal() call. The identical VM is returned and several VM query methods are called to inquire about the associated resources.
program ESMF_VMDefaultBasicsEx
#include "ESMF.h"

use ESMF
use ESMF_TestMod

implicit none

! local variables
integer:: rc
! type(ESMF_VM):: vm
integer:: localPet, petCount, peCount, ssiId, vas

call ESMF_Initialize(vm=vm, defaultlogfilename="VMDefaultBasicsEx.Log", &
logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
! Providing the optional vm argument to ESMF_Initialize() is one way of
! obtaining the global VM.

call ESMF_VMPrint(vm, rc=rc)

call ESMF_VMGetGlobal(vm=vm, rc=rc)
! Calling ESMF_VMGetGlobal() anywhere in the user application is the other
! way to obtain the global VM object.

call ESMF_VMGet(vm, localPet=localPet, petCount=petCount, peCount=peCount, &
rc=rc)
! The VM object contains information about the associated resources. If the
! user code requires this information it must query the VM object.

print *, "This PET is localPet: ", localPet
print *, "of a total of ",petCount," PETs in this VM."
print *, "There are ", peCount," PEs referenced by this VM"

call ESMF_VMGet(vm, localPet, peCount=peCount, ssiId=ssiId, vas=vas, rc=rc)

print *, "This PET is executing in virtual address space (VAS) ", vas
print *, "located on single system image (SSI) ", ssiId
print *, "and is associated with ", peCount," PEs."

end program
48.2.2 Getting the MPI Communicator from an VM object

Sometimes user code requires access to the MPI communicator, e.g. to support legacy code that contains explicit MPI communication calls. The correct way of wrapping such code into ESMF is to obtain the MPI intra-communicator out of the VM object. In order not to interfere with ESMF communications it is advisable to duplicate the communicator before using it in user-level MPI calls. In this example the duplicated communicator is used for a user controlled MPI_Barrier().

```fortran
integer:: mpic

integer:: mpic2

call ESMF_VMGet(vm, mpiCommunicator=mpic, rc=rc)
! The returned MPI communicator spans the same MPI processes that the VM
! is defined on.

call MPI_Comm_dup(mpic, mpic2, ierr)
! Duplicate the MPI communicator not to interfere with ESMF communications.
! The duplicate MPI communicator can be used in any MPI call in the user
! code. Here the MPI_Barrier() routine is called.
call MPI_Barrier(mpic2, ierr)
```

48.2.3 Nesting ESMF inside a user MPI application

It is possible to nest an ESMF application inside a user application that explicitly calls MPI_Init() and MPI_Finalize(). The ESMF_Initialize() call automatically checks whether MPI has already been initialized, and if so does not call MPI_Init() internally. On the finalize side, ESMF_Finalize() can be instructed to not call MPI_Finalize(), making it the responsibility of the outer code to finalize MPI.

```fortran
call MPI_Init(ierr)
! User code initializes MPI.

call ESMF_Initialize(defaultlogfilename="VMUserMpiEx.Log", &
   logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
! ESMF_Initialize() does not call MPI_Init() if it finds MPI initialized.

call ESMF_Finalize(endflag=ESMF_END_KEEPMPI, rc=rc)
! Calling with endflag=ESMF_END_KEEPMPI instructs ESMF_Finalize() to keep
! MPI active.

call MPI_Finalize(ierr)
! It is the responsibility of the outer user code to finalize MPI.
```
48.2.4 Nesting ESMF inside a user MPI application on a subset of MPI ranks

The previous example demonstrated that it is possible to nest an ESMF application, i.e. `ESMF_Initialize()...ESMF_Finalize()` inside `MPI_Init()...MPI_Finalize()`. It is not necessary that all MPI ranks enter the ESMF application. The following example shows how the user code can pass an MPI communicator to `ESMF_Initialize()`, and enter the ESMF application on a subset of MPI ranks.

```fortran
call MPI_Init(ierr)
! User code initializes MPI.

call MPI_Comm_rank(MPI_COMM_WORLD, rank, ierr)
! User code determines the local rank.

! User code prepares MPI communicator "esmfComm" that only contains
! rank 0 and 1.

if (rank < 2) then
    call ESMF_Initialize(mpiCommunicator=esmfComm, &
                        defaultlogfilename="VMUserMpiCommEx.Log", &
                        logkindflag=ESMF_LOGKIND_MULTI, rc=rc)
    ! Only call ESMF_Initialize() on rank 0 and 1, passing the prepared MPI
    ! communicator that spans these ranks.

    call ESMF_Finalize(endflag=ESMF_END_KEEPMPI, rc=rc)
    ! Finalize ESMF without finalizing MPI. The user application will call
    ! MPI_Finalize() on all ranks.
endif

call MPI_Finalize(ierr)
! User code finalizes MPI.
```

48.2.5 VM and Components

The following example shows the role that the VM plays in connection with ESMF Components. A single Component is created in the main program. Through the optional `petList` argument the driver code specifies that only resources associated with PET 0 are given to the `gcomp` object.

When the Component code is invoked through the standard ESMF Component methods Initialize, Run, or Finalize the Component’s VM is automatically entered. Inside of the user-written Component code the Component VM can be obtained by querying the Component object. The VM object will indicate that only a single PET is executing the Component code.
module ESMF_VMComponentEx_gcomp_mod

recursive subroutine mygcomp_init(gcomp, istate, estate, clock, rc)
  type(ESMF_GridComp) :: gcomp
  type(ESMF_State) :: istate, estate
  type(ESMF_Clock) :: clock
  integer, intent(out) :: rc

  ! local variables
  type(ESMF_VM):: vm

  ! get this Component’s vm
  call ESMF_GridCompGet(gcomp, vm=vm)

  ! the VM object contains information about the execution environment of
  ! the Component
  call ESMF_VMPrint(vm, rc=rc)

  rc = 0
end subroutine

recursive subroutine mygcomp_run(gcomp, istate, estate, clock, rc)
  type(ESMF_GridComp) :: gcomp
  type(ESMF_State) :: istate, estate
  type(ESMF_Clock) :: clock
  integer, intent(out) :: rc

  ! local variables
  type(ESMF_VM):: vm

  ! get this Component’s vm
  call ESMF_GridCompGet(gcomp, vm=vm)

  ! the VM object contains information about the execution environment of
  ! the Component
  call ESMF_VMPrint(vm, rc=rc)

  rc = 0
end subroutine

recursive subroutine mygcomp_final(gcomp, istate, estate, clock, rc)
  type(ESMF_GridComp) :: gcomp
  type(ESMF_State) :: istate, estate
  type(ESMF_Clock) :: clock
  integer, intent(out) :: rc

  ! local variables
  type(ESMF_VM):: vm

  ! get this Component’s vm
  call ESMF_GridCompGet(gcomp, vm=vm)

end subroutine
! the VM object contains information about the execution environment of
! the Component

call ESMF_VMPrint(vm, rc=rc)

rc = 0
end subroutine

end module

program ESMF_VMComponentEx
#include "ESMF.h"
use ESMF
use ESMF_TestMod
use ESMF_VMComponentEx_gcomp_mod
implicit none

! local variables

gcomp = ESMF_GridCompCreate(petList=(/0/), rc=rc)

call ESMF_GridCompSetServices(gcomp, userRoutine=mygcomp_register, rc=rc)

call ESMF_GridCompInitialize(gcomp, rc=rc)

call ESMF_GridCompRun(gcomp, rc=rc)

call ESMF_GridCompFinalize(gcomp, rc=rc)

call ESMF_GridCompDestroy(gcomp, rc=rc)

call ESMF_Finalize(rc=rc)

end program

48.2.6 Communication - Send and Recv

The VM layer provides MPI-like point-to-point communication. Use ESMF_VMSend() and ESMF_VMRecv() to pass data between two PETs. The following code sends data from PET 'src' and receives it on PET 'dst'. Both PETs must be part of the same VM.
integer, allocatable:: localData(:)

count = 10
allocate(localData(count))
do i=1, count
  localData(i) = localPet*100 + i
enddo

if (localPet==src) then
  call ESMF_VMSend(vm, sendData=localData, count=count, dstPet=dst, rc=rc)
endif

if (localPet==dst) then
  call ESMF_VMRecv(vm, recvData=localData, count=count, srcPet=src, rc=rc)
endif

48.2.7 Communication - Scatter and Gather

The VM layer provides MPI-like collective communication. ESMF_VMSend() scatters data located on root PET across all the PETs of the VM. ESMF_VMReceive() provides the opposite operation, gathering data from all the PETs of the VM onto root PET.

integer, allocatable:: array1(:,), array2(:)

! allocate data arrays
nsize = 2
nlen = nsize * petCount
allocate(array1(nlen))
allocate(array2(nsize))

! prepare data array1
do i=1, nlen
  array1(i) = localPet * 100 + i
enddo

call ESMF_VMSend(vm, sendData=array1, recvData=map, count=nsize, &
  rootPet=scatterRoot, rc=rc)

call ESMF_VMReceive(vm, sendData=map, recvData=array1, count=nsize, &
  rootPet=gatherRoot, rc=rc)
48.2.8 Communication - AllReduce and AllFullReduce

Use ESMF_VMAllReduce() to reduce data distributed across the PETs of a VM into a result vector, returned on all the PETs. Further, use ESMF_VMAllFullReduce() to reduce the data into a single scalar returned on all PETs.

```fortran
integer, allocatable:: array1(:), array2(:)

! allocate data arrays
nsize = 2
allocate(array1(nsize))
allocate(array2(nsize))

! prepare data array1
do i=1, nsize
  array1(i) = localPet * 100 + i
enddo

call ESMF_VMAllReduce(vm, sendData=array1, recvData=array2, count=nsize, reduceflag=ESMF_REDUCE_SUM, rc=rc)
! Reduce distributed sendData, element by element into recvData and return it on all the PETs.

call ESMF_VMAllFullReduce(vm, sendData=array1, recvData=result, count=nsize, reduceflag=ESMF_REDUCE_SUM, rc=rc)
! Fully reduce the distributed sendData into a single scalar and return it in recvData on all PETs.
```

48.2.9 Using VM communication methods with data of rank greater than one

In the current implementation of the VM communication methods all the data array arguments are declared as assumed shape dummy arrays of rank one. The assumed shape flavor was chosen in order to minimize the chance of copy in/out problems, associated with the other options for declaring the dummy data arguments. However, currently the interfaces are not overloaded for higher ranks. This restriction requires that users that need to communicate data arrays with rank greater than one, must only pass the first dimension of the data array into the VM communication calls. Specifying the full size of the data arrays (considering all dimensions) ensure that the complete data is transferred in or out of the contiguous array memory.

```fortran
integer, allocatable:: sendData(:,:), recvData(:,:,,:)

count1 = 5
count2 = 8
allocate(sendData(count1,count2)) ! 5 x 8 = 40 elements
do j=1, count2
  do i=1, count1
```

1077
sendData(i,j) = localPet*100 + i + (j-1)*count1
enddo
enddo

count1 = 2
count2 = 5
count3 = 1
count4 = 4
allocate(recvData(count1,count2,count3,count4)) ! 2 x 5 x 1 x 4 = 40 elements
do l=1, count4
  do k=1, count3
    do j=1, count2
      do i=1, count1
        recvData(i,j,k,l) = 0
      enddo
    enddo
  enddo
enddo
enddo

if (localPet==src) then
  call ESMF_VMSend(vm, &
    sendData=sendData(:,1), & ! 1st dimension as contiguous array section
    count=count1*count2, & ! total count of elements
    dstPet=dst, rc=rc)
endif

if (localPet==dst) then
  call ESMF_VMRecv(vm, &
    recvData=recvData(:,1,1,1), & ! 1st dimension as contiguous array section
    count=count1*count2*count3*count4, & ! total count of elements
    srcPet=src, rc=rc)
endif

48.3 Restrictions and Future Work

1. **Only array section syntax that leads to contiguous sub sections is supported.** The source and destination arguments in VM communication calls must reference contiguous data arrays. Fortran array sections are not guaranteed to be contiguous in all cases.

2. **Non-blocking Reduce() operations not implemented.** None of the reduce communication calls have an implementation for the non-blocking feature. This affects:
   - ESMF_VMAllFullReduce().
   - ESMF_VMAllReduce().
   - ESMF_VMReduce().

3. **Limitations when using mpiuni mode.** In mpiuni mode non-blocking communications are limited to one outstanding message per source-destination PET pair. Furthermore, in mpiuni mode the message length must be smaller than the internal ESMF buffer size.
4. **Alternative communication paths not accessible.** All user accessible VM communication calls are currently implemented using MPI-1.2. VM's implementation of alternative communication techniques, such as shared memory between threaded PETs and POSIX IPC between PETs located on the same single system image, are currently inaccessible to the user. (One exception to this is the mpiuni case for which the VM automatically utilizes a shared memory path.)

5. **Data arrays in VM comm calls are assumed shape with rank=1.** Currently all dummy arrays in VM comm calls are defined as *assumed shape* arrays of rank=1. The motivation for this choice is that the use of assumed shape dummy arrays guards against the Fortran copy in/out problem. However it may not be as flexible as desired from the user perspective. Alternatively all dummy arrays could be defined as *assumed size* arrays, as it is done in most MPI implementations, allowing arrays of various rank to be passed into the comm methods. Arrays of higher rank can be passed into the current interfaces using Fortran array syntax. This approach is explained in section 48.2.9.

### 48.4 Design and Implementation Notes

The VM class provides an additional layer of abstraction on top of the POSIX machine model, making it suitable for HPC applications. There are four key aspects the VM class deals with.

1. Encapsulation of hardware and operating system details within the concept of Persistent Execution Threads (PETs).
2. Resource management in terms of PETs with a guard against over-subscription.
3. Topological description of the underlying configuration of the compute resources in terms of PETs.
4. Transparent communication API for point-to-point and collective PET-based primitives, hiding the many different communication channels and offering best possible performance.
Definition of terms used in the diagram

- **PE**: A processing element (PE) is an alias for the smallest physical processing unit available on a particular hardware platform. In the language of today’s microprocessor architecture technology a PE is identical to a core, however, if future microprocessor designs change the smallest physical processing unit the mapping of the PE to actual hardware will change accordingly. Thus the PE layer separates the hardware specific part of the VM from the hardware-independent part. Each PE is labeled with an id number which identifies it uniquely within all of the VM instances of an ESMF application.

- **Core**: A Core is the smallest physical processing unit which typically comprises a register set, an integer arithmetic unit, a floating-point unit and various control units. Each Core is labeled with an id number which identifies it uniquely within all of the VM instances of an ESMF application.

- **CPU**: The central processing unit (CPU) houses single or multiple cores, providing them with the interface to system memory, interconnects and IO. Typically the CPU provides some level of caching for the instruction and data streams in and out of the Cores. Cores in a multi-core CPU typically share some caches. Each CPU is labeled with an id number which identifies it uniquely within all of the VM instances of an ESMF application.

- **SSI**: A single system image (SSI) spans all the CPUs controlled by a single running instance of the operating system. SMP and NUMA are typical multi-CPU SSI architectures. Each SSI is labeled with an id number which identifies it uniquely within all of the VM instances of an ESMF application.

- **TOE**: A thread of execution (TOE) executes an instruction sequence. TOE’s come in two flavors: PET and TET.
• PET: A persistent execution thread (PET) executes an instruction sequence on an associated set of data. The PET has a lifetime at least as long as the associated data set. In ESMF the PET is the central concept of abstraction provided by the VM class. The PETs of an VM object are labeled from 0 to N-1 where N is the total number of PETs in the VM object.

• TET: A transient execution thread (TET) executes an instruction sequence on an associated set of data. A TET’s lifetime might be shorter than that of the associated data set.

• OS-Instance: The OS-Instance of a TOE describes how a particular TOE is instantiated on the OS level. Using POSIX terminology a TOE will run as a single thread within a single- or multi-threaded process.

• Pthreads: Communication via the POSIX Thread interface.

• MPI-1, MPI-2: Communication via MPI standards 1 and 2.

• armci: Communication via the aggregate remote memory copy interface.

• SHMEM: Communication via the SHMEM interface.

• OS-IPC: Communication via the operating system’s inter process communication interface. Either POSIX IPC or System V IPC.

• InterCon-lib: Communication via the interconnect’s library native interface. An example is the Elan library for Quadrics.

The POSIX machine abstraction, while a very powerful concept, needs augmentation when applied to HPC applications. Key elements of the POSIX abstraction are processes, which provide virtually unlimited resources (memory, I/O, sockets, ...) to possibly multiple threads of execution. Similarly POSIX threads create the illusion that there is virtually unlimited processing power available to each POSIX process. While the POSIX abstraction is very suitable for many multi-user/multi-tasking applications that need to share limited physical resources, it does not directly fit the HPC workload where over-subscription of resources is one of the most expensive modes of operation.

ESMF’s virtual machine abstraction is based on the POSIX machine model but holds additional information about the available physical processing units in terms of Processing Elements (PEs). A PE is the smallest physical processing unit and encapsulates the hardware details (Cores, CPUs and SSIs).

There is exactly one physical machine layout for each application, and all VM instances have access to this information. The PE is the smallest processing unit which, in today’s microprocessor technology, corresponds to a single Core. Cores are arranged in CPUs which in turn are arranged in SSIs. The setup of the physical machine layout is part of the ESMF initialization process.

On top of the PE concept the key abstraction provided by the VM is the PET. All user code is executed by PETs while OS and hardware details are hidden. The VM class contains a number of methods which allow the user to prescribe how the PETs of a desired virtual machine should be instantiated on the OS level and how they should map onto the hardware. This prescription is kept in a private virtual machine plan object which is created at the same time the associated component is being created. Each time component code is entered through one of the component’s registered top-level methods (Initialize/Run/Finalize), the virtual machine plan along with a pointer to the respective user function is used to instantiate the user code on the PETs of the associated VM in form of single- or multi-threaded POSIX processes.

The process of starting, entering, exiting and shutting down a VM is very transparent, all spawning and joining of threads is handled by VM methods “behind the scenes”. Furthermore, fundamental synchronization and communication primitives are provided on the PET level through a uniform API, hiding details related to the actual instantiation of the participating PETs.
Within a VM object each PE of the physical machine maps to 0 or 1 PETs. Allowing unassigned PEs provides a means to prevent over-subscription between multiple concurrently running virtual machines. Similarly a maximum of one PET per PE prevents over-subscription within a single VM instance. However, over-subscription is possible by subscribing PETs from different virtual machines to the same PE. This type of over-subscription can be desirable for PETs associated with IO work loads expected to be used infrequently and to block often on IO requests.

On the OS level each PET of a VM object is represented by a POSIX thread (Pthread) either belonging to a single- or multi-threaded process and maps to at least 1 PE of the physical machine, ensuring its execution. Mapping a single PET to multiple PEs provides resources for user-level multi-threading, in which case the user code inquires how many PEs are associated with its PET and if there are multiple PEs available the user code can spawn an equal number of threads (e.g. OpenMP) without risking over-subscription. Typically these user spawned threads are short-lived and used for fine-grained parallelization in form of TETs. All PEs mapped against a single PET must be part of a unique SSI in order to allow user-level multi-threading!

In addition to discovering the physical machine the ESMF initialization process sets up the default global virtual machine. This VM object, which is the ultimate parent of all VMs created during the course of execution, contains as many PETs as there are PEs in the physical machine. All of its PETs are instantiated in form of single-threaded MPI processes and a 1:1 mapping of PETs to PEs is used for the default global VM.

The VM design and implementation is based on the POSIX process and thread model as well as the MPI-1.2 standard. As a consequence of the latter standard the number of processes is static during the course of execution and is determined at start-up. The VM implementation further requires that the user starts up the ESMF application with as many MPI processes as there are PEs in the available physical machine using the platform dependent mechanism to ensure proper process placement.

All MPI processes participating in a VM are grouped together by means of an MPI_Group object and their context is defined via an MPI_Comm object (MPI intra-communicator). The PET local process id within each virtual machine is equal to the MPI_Comm_rank in the local MPI_Comm context whereas the PET process id is equal to the MPI_Comm_rank in MPI_COMM_WORLD. The PET process id is used within the VM methods to determine the virtual memory space a PET is operating in.

In order to provide a migration path for legacy MPI-applications the VM offers accessor functions to its MPI_Comm object. Once obtained this object may be used in explicit user-code MPI calls within the same context.

### 48.5 Class API

#### 48.5.1 ESMF_VMAssignment(=) - VM assignment

**INTERFACE:**

```fortran
interface assignment (=)
  vm1 = vm2
end interface
```

**ARGUMENTS:**

```fortran
type(ESMF_VM) :: vm1
type(ESMF_VM) :: vm2
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Assign vm1 as an alias to the same ESMF VM object in memory as vm2. If vm2 is invalid, then vm1 will be equally invalid after the assignment.

The arguments are:

vm1  The ESMF_VM object on the left hand side of the assignment.
vm2  The ESMF_VM object on the right hand side of the assignment.

48.5.2 ESMF_VMOperator(==) - VM equality operator

INTERFACE:

interface operator(==)
  if (vm1 == vm2) then ... endif
  OR
  result = (vm1 == vm2)
end interface

RETURN VALUE:

   logical :: result

ARGUMENTS:

   type(ESMF_VM), intent(in) :: vm1
   type(ESMF_VM), intent(in) :: vm2

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether vm1 and vm2 are valid aliases to the same ESMF VM object in memory. For a more general comparison of two ESMF VMs, going beyond the simple alias test, the ESMF_VMMatch() function (not yet implemented) must be used.

The arguments are:

vm1  The ESMF_VM object on the left hand side of the equality operation.
vm2  The ESMF_VM object on the right hand side of the equality operation.
48.5.3 ESMF_VMOperator(=/=) - VM not equal operator

INTERFACE:

interface operator(=)
    if (vm1 /= vm2) then ... endif
    OR
    result = (vm1 /= vm2)
end interface

RETURN VALUE:

    logical :: result

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm1
    type(ESMF_VM), intent(in) :: vm2

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Test whether vm1 and vm2 are not valid aliases to the same ESMF VM object in memory. For a more general comparison of two ESMF VMs, going beyond the simple alias test, the ESMF_VMMatch() function (not yet implemented) must be used.

The arguments are:

vm1 The ESMF_VM object on the left hand side of the non-equality operation.
vm2 The ESMF_VM object on the right hand side of the non-equality operation.

48.5.4 ESMF_VMAllFullReduce - Fully reduce data across VM, result on all PETs

INTERFACE:

subroutine ESMF_VMAllFullReduce(vm, sendData, recvData, &
    count, reduceflag, syncflag, commhandle, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    <type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
Collective ESMF_VM communication call that reduces a contiguous data array of \(<\text{type}><\text{kind}>\) across the ESMF_VM object into a single value of the same \(<\text{type}><\text{kind}>\). The result is returned on all PETs. Different reduction operations can be specified.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

**Todo:** The current version of this method does not provide an implementation of the non-blocking feature. When calling this method with \(\text{syncflag} = \text{ESMF_SYNC_NONBLOCKING}\) error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:

- \(\text{vm}\) ESMF_VM object.
- \(\text{sendData}\) Contiguous data array holding data to be send. All PETs must specify a valid source array.
- \(\text{recvData}\) Single data variable to be received. All PETs must specify a valid result variable.
- \(\text{count}\) Number of elements in \(\text{sendData}\). Must be the same on all PETs.
- \(\text{reduceflag}\) Reduction operation. See section 50.42 for a list of valid reduce operations.
- \[\text{syncflag}\] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.
- \[\text{commhandle}\] If present, a communication handle will be returned in case of a non-blocking request (see argument \(\text{syncflag}\)). The \text{commhandle} can be used in ESMF_VMCommWait () to block the calling PET until the communication call has finished PET-locally. If no \text{commhandle} was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll () may be used to block on all currently queued communication calls of the VM context.
- \[\text{rc}\] Return code; equals ESMF_SUCCESS if there are no errors.

---

48.5.5 ESMF_VMAllGather - Gather data across VM, result on all PETs

**Interface:**
subroutine ESMF_VMAllGather(vm, sendData, recvData, count, &
   syncflag, commhandle, rc)

ARGUMENTS:

   type(ESMF_VM), intent(in) :: vm
   <type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
   <type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
   integer, intent(in) :: count
   -- The following arguments require argument keyword syntax (e.g. rc=rc). --
   type(ESMF_Sync_Flag), intent(in), optional :: syncflag
   type(ESMF_CommHandle), intent(out), optional :: commhandle
   integer, intent(out), optional :: rc

STATUS:

   • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that gathers contiguous data from all PETs of an ESMF_VM object into an array on all PETs.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL.

The arguments are:

   vm  ESMF_VM object.
   sendData  Contiguous data array holding data to be send. All PETs must specify a valid source array.
   recvData  Contiguous data array for data to be received. All PETs must specify a valid recvData argument.
   count  Number of elements to be gathered from each PET. Must be the same on all PETs.
   [syncflag]  Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section [50.50] for a complete list of options.
   [commanhandle]  If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.
   [rc]  Return code; equals ESMF_SUCCESS if there are no errors.

48.5.6 ESMF_VMAllGatherV - GatherV data across VM, result on all PETs

INTERFACE:
subroutine ESMF_VMAllGatherV(vm, sendData, sendCount, &
recvData, recvCounts, recvOffsets, syncflag, commhandle, rc)

ARGUMENTS:

 type(ESMF_VM), intent(in) :: vm
<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
integer, intent(in) :: sendCount
<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
integer, intent(in) :: recvCounts(:)
integer, intent(in) :: recvOffsets(:)
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Sync_Flag), intent(in), optional :: syncflag

type(ESMF_CommHandle), intent(out), optional :: commhandle
integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that gathers contiguous data from all PETs of an ESMF_VM object into an array on all PETs.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

TODO: The current version of this method does not provide an implementation of the non-blocking feature. When calling this method with syncflag = ESMF_SYNC_NONBLOCKING error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:

- **vm** ESMF_VM object.
- **sendData** Contiguous data array holding data to be send. All PETs must specify a valid source array.
- **sendCount** Number of sendData elements to send from local PET to all other PETs.
- **recvData** Single data variable to be received. All PETs must specify a valid result variable.
- **recvCounts** Number of recvData elements to be received from corresponding source PET.
- **recvOffsets** Offsets in units of elements in recvData marking the start of element sequence to be received from source PET.
- **[syncflag]** Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section [S4.5.0] for a complete list of options.
- **[commhandle]** If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait () to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
48.5.7 ESMF_VMAllReduce - Reduce data across VM, result on all PETs

INTERFACE:

    subroutine ESMF_VMAllReduce(vm, sendData, recvData, count, reduceflag, syncflag, commhandle, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    <type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
    <type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
    integer, intent(in) :: count
    type(ESMF_Reduce_Flag), intent(in) :: reduceflag
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Sync_Flag), intent(in), optional :: syncflag
    type(ESMF_CommHandle), intent(out), optional :: commhandle
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that reduces a contiguous data array across the ESMF_VM object into a contiguous data array of the same <type><kind>. The result array is returned on all PETs. Different reduction operations can be specified.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

TODO: The current version of this method does not provide an implementation of the non-blocking feature. When calling this method with syncflag = ESMF_SYNC_NONBLOCKING error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:

vm ESMF_VM object.

sendData Contiguous data array holding data to be send. All PETs must specify a valid source array.

recvData Single data variable to be received. All PETs must specify a valid result variable.

count Number of elements in sendData and recvData. Must be the same on all PETs.

reduceflag Reduction operation. See section 50.42 for a list of valid reduce operations.

[syncflag] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.

[commhandle] If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait () to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll () may be used to block on all currently queued communication calls of the VM context.
48.5.8 ESMF_VMAllToAll - AllToAll communications across VM

INTERFACE:

subroutine ESMF_VMAllToAll(vm, sendData, sendCount, &
recvData, recvCount, syncflag, &
commhandle, rc)

ARGUMENTS:

type(ESMF_VM), intent(in) :: vm
<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
integer, intent(in) :: sendCount
<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
integer, intent(in) :: recvCount
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Sync_Flag), intent(in), optional :: syncflag
type(ESMF_CommHandle), intent(out), optional :: commhandle
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.3.0r. If code using this interface compiles with any version of ESMF starting with 5.3.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that performs a total exchange operation, sending pieces of the contiguous data buffer sendData to all other PETs while receiving data into the contiguous data buffer recvData from all other PETs.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

TODO: The current version of this method does not provide an implementation of the non-blocking feature. When calling this method with syncflag = ESMF_SYNC_NONBLOCKING error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:

vm ESMF_VM object.
sendData Contiguous data array holding data to be send. All PETs must specify a valid source array.
sendCount Number of sendData elements to send from local PET to each destination PET.
recvData Single data variable to be received. All PETs must specify a valid result variable.
recvCount Number of recvData elements to be received by local PET from each source PET.
[**syncflag**] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 48.5.5 for a complete list of options.

[**commhandle**] If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

[**rc**] Return code; equals ESMF_SUCCESS if there are no errors.

---

### 48.5.9 ESMF_VMAllToAllV - AllToAllV communications across VM

**INTERFACE:**

```fortran
subroutine ESMF_VMAllToAllV(vm, sendData, sendCounts, &
   sendOffsets, recvData, recvCounts, recvOffsets, syncflag, &
   commhandle, rc)
```

**ARGUMENTS:**

- `type(ESMF_VM), intent(in) :: vm`
- `<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)`
- `integer, intent(in) :: sendCounts(:)`
- `integer, intent(in) :: sendOffsets(:)`
- `<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)`
- `integer, intent(in) :: recvCounts(:)`
- `integer, intent(in) :: recvOffsets(:)`
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --`
  - `type(ESMF_Sync_Flag), intent(in), optional :: syncflag`
  - `type(ESMF_CommHandle), intent(out), optional :: commhandle`
  - `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Collective ESMF_VM communication call that performs a total exchange operation, sending pieces of the contiguous data buffer `sendData` to all other PETs while receiving data into the contiguous data buffer `recvData` from all other PETs.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, and logical data types.

**TODO:** The current version of this method does not provide an implementation of the *non-blocking* feature. When calling this method with `syncflag = ESMF_SYNC_NONBLOCKING` error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:
**sendData**  Contiguous data array holding data to be send. All PETs must specify a valid source array.

**sendCounts**  Number of sendData elements to send from local PET to destination PET.

**sendOffsets**  Offsets in units of elements in sendData marking to start of element sequence to be send from local PET to destination PET.

**recvData**  Single data variable to be received. All PETs must specify a valid result variable.

**recvCounts**  Number of recvData elements to be received by local PET from source PET.

**recvOffsets**  Offsets in units of elements in recvData marking to start of element sequence to be received by local PET from source PET.

**[syncflag]**  Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.

**[commhandle]**  If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

**48.5.10  ESMF_VMBarrier - VM wide barrier**

**INTERFACE:**

```fortran
subroutine ESMF_VMBarrier(vm, rc)
  ! ARGUMENTS:
  type(ESMF_VM), intent(in) :: vm
  integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Collective ESMF_VM communication call that blocks calling PET until all PETs of the VM context have issued the call.

The arguments are:

**vm**  ESMF_VM object.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.
48.5.11  ESMF_VMBroadcast - Broadcast data across VM

INTERFACE:

    subroutine ESMF_VMBroadcast(vm, bcstData, count, rootPet, &
        syncflag, commhandle, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    <type>(ESMF_KIND_<kind>), target, intent(inout) :: bcstData(:)
    integer, intent(in) :: count
    integer, intent(in) :: rootPet
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    type(ESMF_Sync_Flag), intent(in), optional :: syncflag
    type(ESMF_CommHandle), intent(out), optional :: commhandle
    integer, intent(out), optional :: rc

STATUS:

•  This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that broadcasts a contiguous data array from rootPet to all other PETs of the ESMF_VM object.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL, ESMF_TYPEKIND_CHARACTER.

The arguments are:

vm  ESMF_VM object.
bcstData  Contiguous data array. On rootPet bcstData holds data that is to be broadcasted to all other PETs. On all other PETs bcstData is used to receive the broadcasted data.
count  Number of elements in sendData and recvData. Must be the same on all PETs.
rootPet  PET that holds data that is being broadcast.
[syncflag]  Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section [SYNC] for a complete list of options.
[commhandle]  If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
48.5.12  ESMF_VMCommWait - Wait for non-blocking VM communication to complete

INTERFACE:

    subroutine ESMF_VMCommWait(vm, commhandle, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    type(ESMF_CommHandle), intent(in) :: commhandle
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Wait for non-blocking VM communication specified by the commhandle to complete.
The arguments are:

vm  ESMF_VM object.

commhandle  Handle specifying a previously issued non-blocking communication request.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

48.5.13  ESMF_VMCommWaitAll - Wait for all non-blocking VM comms to complete

INTERFACE:

    subroutine ESMF_VMCommWaitAll(vm, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Wait for all pending non-blocking VM communication within the specified VM context to complete.

The arguments are:

vm ESMF_VM object.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

48.5.14 ESMF_VMGather - Gather data from across VM

INTERFACE:

```fortran
subroutine ESMF_VMGather(vm, sendData, recvData, count, rootPet, &
                        syncflag, commhandle, rc)
```

ARGUMENTS:

```fortran
  type(ESMF_VM), intent(in) :: vm
  <type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
  <type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
  integer, intent(in) :: count
  integer, intent(in) :: rootPet
  type(ESMF_Sync_Flag), intent(in), optional :: syncflag
  type(ESMF_CommHandle), intent(out), optional :: commhandle
  integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that gathers contiguous data from all PETs of an ESMF_VM object (including rootPet) into an array on rootPet.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL.

The arguments are:

vm ESMF_VM object.

sendData Contiguous data array holding data to be send. All PETs must specify a valid source array.

recvData Contiguous data array for data to be received. Only the recvData array specified by the rootPet will be used by this method.
count  Number of elements to be send from each PET to rootPet. Must be the same on all PETs.

rootPet  PET on which data is gathered.

syncflag  Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.

commhandle  If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

rc  Return code; equals ESMF_SUCCESS if there are no errors.

48.5.15  ESMF_VMGatherV - GatherV data from across VM

INTERFACE:

```
subroutine ESMF_VMGatherV(vm, sendData, sendCount, recvData, & recvCounts, recvOffsets, rootPet, rc)
```

ARGUMENTS:

- `type(ESMF_VM), intent(in) :: vm`  
- `<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)`  
- `integer, intent(in) :: sendCount`  
- `<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)`  
- `integer, intent(in) :: recvCounts(:)`  
- `integer, intent(in) :: recvOffsets(:)`  
- `integer, intent(in) :: rootPet`  
- `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that gathers contiguous data from all PETs of an ESMF_VM object into an array on rootPet.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

TODO: The current version of this method does not provide an implementation of the non-blocking feature. When calling this method with syncflag = ESMF_SYNC_NONBLOCKING error code ESMF_RC_NOT_IMPL will be returned and an error will be logged.

The arguments are:
vm ESMF_VM object.

**sendData**  Contiguous data array holding data to be send. All PETs must specify a valid source array.

**sendCount**  Number of sendData elements to send from local PET to all other PETs.

**recvData**  Single data variable to be received. All PETs must specify a valid result variable.

**recvCounts**  Number of recvData elements to be received from corresponding source PET.

**recvOffsets**  Offsets in units of elements in recvData marking the start of element sequence to be received from source PET.

**rootPet**  PET on which data is gathered.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 48.5.16 ESMF_VMGet - Get object-wide information from a VM

**INTERFACE:**

```fortran
! Private name; call using ESMF_VMGet()
subroutine ESMF_VMGetDefault(vm, localPet, petCount, &
   peCount, mpiCommunicator, pthreadsEnabledFlag, openMPEncabledFlag, rc)
```

**ARGUMENTS:**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type(ESMF_VM), intent(in) :: vm</td>
<td>-- The following arguments require argument keyword syntax (e.g. rc=rc). --</td>
</tr>
<tr>
<td>integer, intent(out), optional :: localPet</td>
<td></td>
</tr>
<tr>
<td>integer, intent(out), optional :: petCount</td>
<td></td>
</tr>
<tr>
<td>integer, intent(out), optional :: peCount</td>
<td></td>
</tr>
<tr>
<td>integer, intent(out), optional :: mpiCommunicator</td>
<td></td>
</tr>
<tr>
<td>logical, intent(out), optional :: pthreadsEnabledFlag</td>
<td></td>
</tr>
<tr>
<td>logical, intent(out), optional :: openMPEncabledFlag</td>
<td></td>
</tr>
<tr>
<td>integer, intent(out), optional :: rc</td>
<td></td>
</tr>
</tbody>
</table>

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Get internal information about the specified ESMF_VM object.

The arguments are:

**vm**  Queried ESMF_VM object.

[localPet]  Upon return this holds the id of the PET that issued this call.
Upon return this holds the number of PETs in the specified ESMF_VM object.

Upon return this holds the number of PEs referenced by the specified ESMF_VM object.

Upon return this holds the MPI intra-communicator used by the specified ESMF_VM object. This communicator may be used for user-level MPI communications. It is recommended that the user duplicates the communicator via MPI_Comm_Dup() in order to prevent any interference with ESMF communications.

.TRUE. ESMF has been compiled with Pthreads.
.FALSE. ESMF has not been compiled with Pthreads.

.TRUE. ESMF has been compiled with OpenMP.
.FALSE. ESMF has not been compiled with OpenMP.

Return code; equals ESMF_SUCCESS if there are no errors.

48.5.17 ESMF_VMGet - Get PET-local VM information

INTERFACE:

! Private name; call using ESMF_VMGet()
subroutine ESMF_VMGetPetLocalInfo(vm, pet, peCount, ssiId, &
  threadCount, threadId, vas, rc)

ARGUMENTS:

  type(ESMF_VM), intent(in) :: vm
  integer, intent(in) :: pet
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: peCount
  integer, intent(out), optional :: ssiId
  integer, intent(out), optional :: threadCount
  integer, intent(out), optional :: threadId
  integer, intent(out), optional :: vas
  integer, intent(out), optional :: rc

STATUS:

  • This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get internal information about a specific PET within an ESMF_VM object.

The arguments are:

  vm  Queried ESMF_VM object.
  pet  Queried PET id within the specified ESMF_VM object.
Upon return this holds the number of PEs associated with the specified PET in the ESMF_VM object.

Upon return this holds the id of the single-system image (SSI) the specified PET is running on.

Upon return this holds the number of PETs in the specified PET’s thread group.

Upon return this holds the thread id of the specified PET within the PET’s thread group.

Virtual address space in which this PET operates.

Return code; equals ESMF_SUCCESS if there are no errors.

48.5.18 ESMF_VMGetGlobal - Get Global VM

INTERFACE:

subroutine ESMF_VMGetGlobal(vm, rc)

ARGUMENTS:

  type(ESMF_VM), intent(out) :: vm
  -- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get the global ESMF_VM object. This is the VM object that is created during ESMF_Initialize() and is the ultimate parent of all VM objects in an ESMF application. It is identical to the VM object returned by ESMF_Initialize(..., vm=vm, ...).

The ESMF_VMGetGlobal() call provides access to information about the global execution context via the global VM. This call is necessary because ESMF does not created a global ESMF Component during ESMF_Initialize() that could be queried for information about the global execution context of an ESMF application.

Usage of ESMF_VMGetGlobal() from within Component code is strongly discouraged. ESMF Components should only access their own VM objects through Component methods. Global information, if required by the Component user code, should be passed down to the Component from the driver through the Component calling interface.

The arguments are:

vm Upon return this holds the ESMF_VM object of the global execution context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.
48.5.19 ESMF_VMGetCurrent - Get Current VM

INTERFACE:

```fortran
subroutine ESMF_VMGetCurrent(vm, rc)
```

ARGUMENTS:

```fortran
type(ESMF_VM), intent(out) :: vm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get the ESMF_VM object of the current execution context. Calling ESMF_VMGetCurrent() within an ESMF Component, will return the same VM object as ESMF_GridCompGet(..., vm=vm, ...) or ESMF_CplCompGet(..., vm=vm, ...).

The main purpose of providing ESMF_VMGetCurrent() is to simplify ESMF adoption in legacy code. Specifically, code that uses MPI_COMM_WORLD deep within its calling tree can easily be modified to use the correct MPI communicator of the current ESMF execution context. The advantage is that these modifications are very local, and do not require wide reaching interface changes in the legacy code to pass down the ESMF component object, or the MPI communicator.

The use of ESMF_VMGetCurrent() is strongly discouraged in newly written Component code. Instead, the ESMF Component object should be used as the appropriate container of ESMF context information. This object should be passed between the subroutines of a Component, and be queried for any Component specific information.

Outside of a Component context, i.e. within the driver context, the call to ESMF_VMGetCurrent() is identical to ESMF_VMGetGlobal().

The arguments are:

- **vm** Upon return this holds the ESMF_VM object of the current execution context.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

48.5.20 ESMF_VMPrint - Print VM information

INTERFACE:

```fortran
subroutine ESMF_VMPrint(vm, rc)
```

ARGUMENTS:

```fortran
```

The arguments are:

- **vm** Upon return this holds the ESMF_VM object of the current execution context.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.
**ESMF_VM**

```fortran
  type(ESMF_VM), intent(in) :: vm
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Print internal information about the specified ESMF_VM to stdout.

The arguments are:

- **vm** Specified ESMF_VM object.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

---

**48.5.21 ESMF_VMRecv - Receive data from srcPet**

**INTERFACE:**

```fortran
  subroutine ESMF_VMRecv(vm, recvData, count, srcPet, &
    syncflag, commhandle, rc)
```

**ARGUMENTS:**

```fortran
  type(ESMF_VM),                intent(in)  :: vm
  integer(ESMF_KIND_I4), target, intent(out) :: recvData(:)
  integer,                      intent(in)  :: count
  integer,                      intent(in)  :: srcPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  type(ESMF_Sync_Flag),         intent(in), optional :: syncflag
  type(ESMF_CommHandle),        intent(out), optional :: commhandle
  integer,                      intent(out), optional :: rc
```

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

**DESCRIPTION:**

Receive contiguous data from srcPet within the same ESMF_VM object.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL, ESMF_TYPEKIND_CHARACTER.

The arguments are:
INTERFACE:

subroutine ESMF_VMReduce(vm, sendData, recvData, count, &
reduceflag, rootPet, syncflag, commhandle, rc)

ARGUMENTS:

type(ESMF_VM), intent(in) :: vm
<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
integer, intent(in) :: count
integer, intent(in) :: reduceflag
integer, intent(in) :: rootPet

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
type(ESMF_Sync_Flag), intent(in), optional :: syncflag
integer, intent(out), optional :: commhandle
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_VM communication call that reduces a contiguous data array across the ESMF_VM object into a contiguous data array of the same <type><kind>. The result array is returned on rootPet. Different reduction operations can be specified.

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.
TODO: The current version of this method does not provide an implementation of the *non-blocking* feature. When calling this method with `syncflag = ESMF_SYNC_NONBLOCKING` error code `ESMF_RC_NOT_IMPL` will be returned and an error will be logged.

The arguments are:

**vm** `ESMF_VM` object.

**sendData** Contiguous data array holding data to be send. All PETs must specify a valid source array.

**recvData** Single data variable to be received. All PETs must specify a valid result variable.

**count** Number of elements in `sendData` and `recvData`. Must be the same on all PETs.

**reduceflag** Reduction operation. See section 50.42 for a list of valid reduce operations.

**rootPet** PET on which reduced data is returned.

**[syncflag]** Flag indicating whether this call behaves blocking or non-blocking. The default is `ESMF_SYNC_BLOCKING`. See section 50.50 for a complete list of options.

**[commhandle]** If present, a communication handle will be returned in case of a non-blocking request (see argument `syncflag`). The `commhandle` can be used in `ESMF_VMCommWait()` to block the calling PET until the communication call has finished PET-locally. If no `commhandle` was supplied to a non-blocking call the VM method `ESMF_VMCommWaitAll()` may be used to block on all currently queued communication calls of the VM context.

**[rc]** Return code; equals `ESMF_SUCCESS` if there are no errors.

---

### 48.5.23 ESMF_VMScatter - Scatter data across VM

**INTERFACE:**

```fortran
subroutine ESMF_VMScatter(vm, sendData, recvData, count, & rootPet, syncflag, commhandle, rc)
```

**ARGUMENTS:**

- `type(ESMF_VM), intent(in) :: vm`
- `<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)`
- `<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)`
- `integer, intent(in) :: count`
- `integer, intent(in) :: rootPet`
- `type(ESMF_Sync_Flag), intent(in), optional :: syncflag`
- `type(ESMF_CommHandle), intent(out), optional :: commhandle`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Collective ESMF_VM communication call that scatters contiguous data from the rootPet to all PETs across the ESMF_VM object (including rootPet).

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL.

The arguments are:

vm ESMF_VM object.

sendData Contiguous data array holding data to be send. Only the sendData array specified by the rootPet will be used by this method.

recvData Contiguous data array for data to be received. All PETs must specify a valid destination array.

count Number of elements to be send from rootPet to each of the PETs. Must be the same on all PETs.

rootPet PET that holds data that is being scattered.

[syncflag] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.

[commhandle] If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

48.5.24 ESMF_VMScatterV - ScatterV across VM

INTERFACE:

```
subroutine ESMF_VMScatterV(vm, sendData, sendCounts, &
 sendOffsets, recvData, recvCount, rootPet, rc)
```

ARGUMENTS:

```
type(ESMF_VM), intent(in) :: vm
<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
integer, intent(in) :: sendCounts(:)
integer, intent(in) :: sendOffsets(:)
<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)
integer, intent(in) :: recvCount
integer, intent(in) :: rootPet
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:
This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Collective ESMF_Vm communication call that scatters contiguous data from the rootPet to all PETs across the ESMF_Vm object (including rootPet).

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8.

The arguments are:

- **vm** ESMF_Vm object.
- **sendData** Contiguous data array holding data to be send. Only the sendData array specified by the rootPet will be used by this method.
- **sendCounts** Number of sendData elements to be send to corresponding receive PET.
- **sendOffsets** Offsets in units of elements in sendData marking the start of element sequence to be send to receive PET.
- **recvData** Single data variable to be received. All PETs must specify a valid result variable.
- **recvCount** Number of recvData elements to receive by local PET from rootPet.
- **rootPet** PET that holds data that is being scattered.
- **[rc]** Return code; equals ESMF_SUCCESS if there are no errors.

48.5.25 ESMF_VMSend - Send data to dstPet

INTERFACE:

```fortran
subroutine ESMF_VMSend(vm, sendData, count, dstPet, &
   syncflag, commhandle, rc)
   type(ESMF_VM), intent(in) :: vm
   type(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)
   integer, intent(in) :: count
   integer, intent(in) :: dstPet
   type(ESMF_Sync_Flag), intent(in), optional :: syncflag
   type(ESMF_CommHandle), intent(out), optional :: commhandle
   integer, intent(out), optional :: rc
```

ARGUMENTS:

- **type(ESMF_VM), intent(in) :: vm**
- **type(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)**
- **integer, intent(in) :: count**
- **integer, intent(in) :: dstPet**
- **type(ESMF_Sync_Flag), intent(in), optional :: syncflag**
- **type(ESMF_CommHandle), intent(out), optional :: commhandle**
- **integer, intent(out), optional :: rc**

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Send contiguous data to dstPet within the same ESMF_VM object.

The arguments are:

- **vm** ESMF_VM object.
- **sendData** Contiguous data array holding data to be send.
- **count** Number of elements to be send.
- **dstPet** Receiving PET.

[syncflag] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.30 for a complete list of options.

[commhandle] If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

---

48.5.26 ESMF_VMSendRecv - Send and Recv data to and from PETs

INTERFACE:

```fortran
subroutine ESMF_VMSendRecv(vm, sendData, sendCount, dstPet, &
recvData, recvCount, srcPet, syncflag, commhandle, rc)
```

ARGUMENTS:

- `type(ESMF_VM), intent(in) :: vm`
- `<type>(ESMF_KIND_<kind>), target, intent(in) :: sendData(:)`
- `integer, intent(in) :: sendCount`
- `integer, intent(in) :: dstPet`
- `<type>(ESMF_KIND_<kind>), target, intent(out) :: recvData(:)`
- `integer, intent(in) :: recvCount`
- `integer, intent(in) :: srcPet`

-- The following arguments require argument keyword syntax (e.g. rc=rc). --
- `type(ESMF_Sync_Flag), intent(in), optional :: syncflag`
- `type(ESMF_CommHandle), intent(out), optional :: commhandle`
- `integer, intent(out), optional :: rc`

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Send contiguous data to dstPet within the same ESMF_VM object while receiving contiguous data from srcPet within the same ESMF_VM object. The sendData and recvData arrays must be disjoint!

This method is overloaded for: ESMF_TYPEKIND_I4, ESMF_TYPEKIND_R4, ESMF_TYPEKIND_R8, ESMF_TYPEKIND_LOGICAL, ESMF_TYPEKIND_CHARACTER.

The arguments are:

vm ESMF_VM object.

sendData Contiguous data array holding data to be send.

sendCount Number of elements to be send.

dstPet PET that holds recvData.

recvData Contiguous data array for data to be received.

recvCount Number of elements to be received.

srcPet PET that holds sendData.

[syncflag] Flag indicating whether this call behaves blocking or non-blocking. The default is ESMF_SYNC_BLOCKING. See section 50.50 for a complete list of options.

[commhandle] If present, a communication handle will be returned in case of a non-blocking request (see argument syncflag). The commhandle can be used in ESMF_VMCommWait() to block the calling PET until the communication call has finished PET-locally. If no commhandle was supplied to a non-blocking call the VM method ESMF_VMCommWaitAll() may be used to block on all currently queued communication calls of the VM context.

[rc] Return code; equals ESMF_SUCCESS if there are no errors.

48.5.27 ESMF_VMValidate - Validate VM internals

INTERFACE:

    subroutine ESMF_VMValidate(vm, rc)

ARGUMENTS:

    type(ESMF_VM), intent(in) :: vm
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

Validates that the vm is internally consistent. The method returns an error code if problems are found.
The arguments are:

vm  Specified ESMF_VM object.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

48.5.28  ESMF_VMWtime - Get floating-point number of seconds

INTERFACE:

subroutine ESMF_VMWtime(time, rc)

ARGUMENTS:

real(ESMF_KIND_R8), intent(out) :: time
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get floating-point number of seconds of elapsed wall-clock time since some time in the past.
The arguments are:

time  Time in seconds.
[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

48.5.29  ESMF_VMWtimeDelay - Delay execution

INTERFACE:

subroutine ESMF_VMWtimeDelay(delay, rc)

ARGUMENTS:
real(ESMF_KIND_R8), intent(in) :: delay
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Delay execution for amount of seconds.

The arguments are:

delay  Delay time in seconds.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

48.5.30  ESMF_VMWtimePrec - Timer precision as floating-point number of seconds

INTERFACE:

subroutine ESMF_VMWtimePrec(prec, rc)

ARGUMENTS:

real(ESMF_KIND_R8), intent(out) :: prec
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Get a run-time estimate of the timer precision as floating-point number of seconds. This is a relatively expensive call since the timer precision is measured several times before the maximum is returned as the estimate. The returned value is PET-specific and may differ across the VM context.

The arguments are:

prec  Timer precision in seconds.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.
49 Fortran I/O and System Utilities

49.1 Description

The ESMF Fortran I/O and System utilities provide portable methods to access capabilities which are often implemented in different ways amongst different environments. These utility methods are divided into three groups: command line access, Fortran I/O, and sorting.

Command line arguments may be accessed using three methods: ESMF_UtilGetArg() returns a given command line argument, ESMF_UtilGetArgCount() returns a count of the number of command line arguments available. Finally, the ESMF_UtilGetArgIndex() method returns the index of a desired argument value, given its keyword name.

Two I/O methods are implemented: ESMF_IOUnitGet(), to obtain an unopened Fortran unit number within the range of unit numbers that ESMF is allowed to use, and ESMF_IOUnitFlush() to flush the I/O buffer associated with a specific Fortran unit.

Finally, the ESMF_UtilSort() method sorts integer, floating point, and character string data types in either ascending or descending order.

49.2 Use and Examples

49.2.1 Fortran unit number management

The ESMF_UtilIOUnitGet() method is provided so that applications using ESMF can remain free of unit number conflicts — both when combined with other third party code, or with ESMF itself. This call is typically used just prior to an OPEN statement:

```fortran
call ESMF_UtilIOUnitGet (unit=grid_unit, rc=rc)
open (unit=grid_unit, file='grid_data.dat', status='old', action='read')
```

By default, unit numbers between 50 and 99 are scanned to find an unopened unit number.

Internally, ESMF also uses ESMF_UtilIOUnitGet() when it needs to open Fortran unit numbers for file I/O. By using the same API for both user and ESMF code, unit number collisions can be avoided.

When integrating ESMF into an application where there are conflicts with other uses of the same unit number range, such as when hard-coded unit number values are used, an alternative unit number range can be specified. The ESMF_Initialize() optional arguments IOUnitLower and IOUnitUpper may be set as needed. Note that IOUnitUpper must be set to a value higher than IOUnitLower, and that both must be non-negative. Otherwise ESMF_Initialize will return a return code of ESMF_FAILURE. ESMF itself does not typically need more than about five units for internal use.

```fortran
call ESMF_Initialize (..., IOUnitLower=120, IOUnitUpper=140)
```

All current Fortran environments have preconnected unit numbers, such as units 5 and 6 for standard input and output, in the single digit range. So it is recommended that the unit number range is chosen to begin at unit 10 or higher to avoid these preconnected units.
49.2.2 Flushing output

Fortran run-time libraries generally use buffering techniques to improve I/O performance. However output buffering can be problematic when output is needed, but is “trapped” in the buffer because it is not full. This is a common occurrence when debugging a program, and inserting WRITE statements to track down the bad area of code. If the program crashes before the output buffer has been flushed, the desired debugging output may never be seen — giving a misleading indication of where the problem occurred. It would be desirable to ensure that the output buffer is flushed at predictable points in the program in order to get the needed results. Likewise, in parallel code, predictable flushing of output buffers is a common requirement, often in conjunction with ESMF_VMBarrier() calls.

The ESMF_UtilIOUnitFlush() API is provided to flush a unit as desired. Here is an example of code which prints debug values, and serializes the output to a terminal in PET order:

```fortran
  type(ESMF_VM) :: vm
  integer :: tty_unit
  integer :: me, npets

  call ESMF_Initialize (vm=vm, rc=rc)
  call ESMF_VMGet (vm, localPet=me, petCount=npets)

  call ESMF_UtilIOUnitGet (unit=tty_unit)
  open (unit=tty_unit, file='/dev/tty', status='old', action='write')
...
  call ESMF_VMBarrier (vm=vm)
  do, i=0, npets-1
    if (i == me) then
      write (tty_unit, *) 'PET: ', i, ', values are: ', a, b, c
      call ESMF_UtilIOUnitFlush (unit=tty_unit)
    end if
  end do
  call ESMF_VMBarrier (vm=vm)
```

49.3 Design and Implementation Notes

49.3.1 Fortran unit number management

When ESMF needs to open a Fortran I/O unit, it calls ESMF_IOUnitGet() to find an unopened unit number. As delivered, the range of unit numbers that are searched are between ESMF_LOG_FORTRAN_UNIT_NUMBER (normally set to 50), and ESMF_LOG_UPPER (normally set to 99.) Unopened unit numbers are found by using the Fortran INQUIRE statement.

When integrating ESMF into an application where there are conflicts with other uses of the same unit number range, an alternative range can be specified in the ESMF_Initialize() call by setting the IOUnitLower and IOUnitUpper arguments as needed. ESMF_IOUnitGet() will then search the alternate range of unit numbers. Note that IOUnitUpper must be set to a value higher than IOUnitLower, and that both must be non-negative. Otherwise ESMF_Initialize will return a return code of ESMF_FAILURE.

Fortran unit numbers are not standardized in the Fortran 90 Standard. The standard only requires that they be non-negative integers. But other than that, it is up to the compiler writers and application developers to provide and use units which work with the particular implementation. For example, units 5 and 6 are a defacto standard for "standard
input” and “standard output” — even though this is not specified in the actual Fortran standard. The Fortran standard also does not specify which unit numbers can be used, nor does it specify how many can be open simultaneously.

Since all current compilers have preconnected unit numbers, and these are typically found on units lower than 10, it is recommended that applications use unit numbers 10 and higher.

### 49.3.2 Flushing output

When ESMF needs to flush a Fortran unit, the `ESMF_IOUnitFlush()` API is used to centralize the file flushing capability, because Fortran has not historically had a standard mechanism for flushing output buffers. Most compilers run-time libraries support various library extensions to provide this functionality — though, being non-standard, the spelling and number of arguments vary between implementations. Fortran 2003 also provides for a `FLUSH` statement which is built into the language. When possible, `ESMF_IOUnitFlush()` uses the F2003 `FLUSH` statement. With older compilers, the appropriate library call is made.

### 49.3.3 Sorting algorithms

The `ESMF_UtilSort()` algorithms are the same as those in the LAPACK sorting procedures `SLASRT()` and `DLASRT()`. Two algorithms are used. For small sorts, arrays with 20 or fewer elements, a simple Insertion sort is used. For larger sorts, a Quicksort algorithm is used.

Compared to the original LAPACK code, a full Fortran 90 style interface is supported for ease of use and enhanced compile time checking. Additional support is also provided for integer and character string data types.

### 49.4 Utility API

#### 49.4.1 ESMF_UtilGetArg - Return a command line argument

**INTERFACE:**

```fortran
subroutine ESMF_UtilGetArg(argindex, argvalue, arglength, rc)
```

**ARGUMENTS:**

- `integer, intent(in) :: argindex`
- `character( * ), intent(out), optional :: argvalue`
- `integer, intent(out), optional :: arglength`
- `integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.
DESCRIPTION:

This method returns a copy of a command line argument specified when the process was started. This argument is the same as an equivalent C++ program would find in the argv array.

Some MPI implementations do not consistently provide command line arguments on PETs other than PET 0. It is therefore recommended that PET 0 call this method and broadcast the results to the other PETs by using the ESMF_VMBroadcast() method.

The arguments are:

**argindex**  A non-negative index into the command line argument argv array. If argindex is negative or greater than the number of user-specified arguments, ESMF_RC_ARG_VALUE is returned in the rc argument.

**[argvalue]**  Returns a copy of the desired command line argument. If the provided character string is longer than the command line argument, the string will be blank padded. If the string is too short, truncation will occur and ESMF_RC_ARG_SIZE is returned in the rc argument.

**[arglength]**  Returns the length of the desired command line argument in characters. The length result does not depend on the length of the value string. It may be used to query the length of the argument.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

### 49.4.2 ESMF_UtilGetArgC - Return number of command line arguments

INTERFACE:

```fortran
subroutine ESMF_UtilGetArgC(count, rc)
```

ARGUMENTS:

```fortran
integer, intent(out) :: count
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc
```

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method returns the number of command line arguments specified when the process was started.

The number of arguments returned does not include the name of the command itself - which is typically returned as argument zero.

Some MPI implementations do not consistently provide command line arguments on PETs other than PET 0. It is therefore recommended that PET 0 call this method and broadcast the results to the other PETs by using the ESMF_VMBroadcast() method.

The arguments are:
count  Count of command line arguments.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

49.4.3 ESMF_UtilGetArgIndex - Return the index of a command line argument

INTERFACE:

    subroutine ESMF_UtilGetArgIndex(argvalue, argindex, rc)

ARGUMENTS:

    character(*), intent(in) :: argvalue
    integer, intent(out), optional :: argindex
    integer, intent(out), optional :: rc

STATUS:

• This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

This method searches for, and returns the index of a desired command line argument. An example might be to find a specific keyword (e.g., -esmf_path) so that its associated value argument could be obtained by adding 1 to the argindex and calling ESMF_UtilGetArg().

Some MPI implementations do not consistently provide command line arguments on PETs other than PET 0. It is therefore recommended that PET 0 call this method and broadcast the results to the other PETs by using the ESMF_VMBroadcast() method.

The arguments are:

argvalue  A character string which will be searched for in the command line argument list.

[argindex]  If the value string is found, the position will be returned as a non-negative integer. If the string is not found, a negative value will be returned.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

49.4.4 ESMF_UtilIOGetCWD - Get the current directory

INTERFACE:
subroutine ESMF_UtilIOGetCWD (pathName, rc)

PARAMETERS:

character(*) , intent(in) :: pathName
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(out), optional :: rc

DESCRIPTION:

Call the system-dependent routine to get the current directory from the file system.

The arguments are:

pathName Name of the directory to be retrieved.
[rc] Return code; equals ESMF_SUCCESS if there are no errors.

49.4.5 ESMF_UtilIOMkDir - Create a directory in the file system

INTERFACE:

subroutine ESMF_UtilIOMkDir (pathName, &
   mode, relaxedFlag, &
   rc)

PARAMETERS:

character(*) , intent(in) :: pathName
-- The following arguments require argument keyword syntax (e.g. rc=rc). --
integer, intent(in), optional :: mode
logical, intent(in), optional :: relaxedFlag
integer, intent(out), optional :: rc

DESCRIPTION:

Call the system-dependent routine to create a directory in the file system.

The arguments are:

pathName Name of the directory to be created.
[mode] File permission mode. If not specified on POSIX-compliant systems, the default is o’755’. On native Windows, this argument is ignored and default security settings are used.
[relaxedFlag] When set to .true., if the directory already exists, rc will be set to ESMF_SUCCESS instead of an error. If not specified, the default is .false..
[rc] Return code; equals ESMF_SUCCESS if there are no errors.
49.4.6  ESMF_UtilIORmDir - Remove a directory from the file system

INTERFACE:

    subroutine ESMF_UtilIORmDir (pathName, &
        relaxedFlag, rc)

PARAMETERS:

    character(*), intent(in) :: pathName
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    logical, intent(in), optional :: relaxedFlag
    integer, intent(out), optional :: rc

DESCRIPTION:

Call the system-dependent routine to remove a directory from the file system. Note that the directory must be empty in order to be successfully removed.

The arguments are:

pathName  Name of the directory to be removed.

[relaxedFlag]  If set to .true., and if the specified directory does not exist, the error is ignored and rc will be set to ESMF_SUCCESS. If not specified, the default is .false.

[rc]  Return code; equals ESMF_SUCCESS if there are no errors.

49.4.7  ESMF_UtilIOUnitFlush - Flush output on a unit number

INTERFACE:

    subroutine ESMF_UtilIOUnitFlush(unit, rc)

PARAMETERS:

    integer, intent(in) :: unit
    -- The following arguments require argument keyword syntax (e.g. rc=rc). --
    integer, intent(out), optional :: rc

STATUS:

- This interface is backward compatible with ESMF versions starting at 5.2.0r. If code using this interface compiles with any version of ESMF starting with 5.2.0r, then it will compile with the current version.

DESCRIPTION:

Call the system-dependent routine to force output on a specific Fortran unit number.

The arguments are:
**unit**  A Fortran I/O unit number. If the unit is not connected to a file, no flushing occurs.

**[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 49.4.8 ESMF_UtilIOUnitGet - Scan for a free I/O unit number

**INTERFACE:**

```fortran
subroutine ESMF_UtilIOUnitGet(unit, rc)
```

**ARGUMENTS:**

- `integer, intent(out) :: unit`
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc`

**STATUS:**

- This interface is backward compatible with ESMF versions starting at 5.2.0. If code using this interface compiles with any version of ESMF starting with 5.2.0, then it will compile with the current version.

**DESCRIPTION:**

Scan for, and return, a free Fortran I/O unit number. By default, the range of unit numbers returned is between 50 and 99 (parameters ESMF_LOG_FORTRAN_UNIT_NUMBER and ESMF_LOG_UPPER respectively.) When integrating ESMF into an application where these values conflict with other usages, the range of values may be moved by setting the optional IOUnitLower and IOUnitUpper arguments in the initial ESMF_Initialize() call with values in a safe, alternate, range.

The Fortran unit number which is returned is not reserved in any way. Successive calls without intervening OPEN or CLOSE statements (or other means of connecting to units), might not return a unique unit number. It is recommended that an OPEN statement immediately follow the call to ESMF_IOUnitGet() to activate the unit.

The arguments are:

- **unit**  A Fortran I/O unit number.
- **[rc]**  Return code; equals ESMF_SUCCESS if there are no errors.

---

### 49.4.9 ESMF_UtilSort - Sort data

**INTERFACE:**

```fortran
subroutine ESMF_UtilSort (list, direction, rc)
```

**ARGUMENTS:**

- `integer, intent(out) :: unit`
- `-- The following arguments require argument keyword syntax (e.g. rc=rc). --
  integer, intent(out), optional :: rc`
<list>, see below for supported values

```fortran
  type(ESMF_SortFlag), intent(in) :: direction
  integer, intent(out), optional :: rc
```

**DESCRIPTION:**

Supported values for `<list>` are:

- integer(ESMF_KIND_I4), intent(inout) :: list(:)
- integer(ESMF_KIND_I8), intent(inout) :: list(:)
- real(ESMF_KIND_R4), intent(inout) :: list(:)
- real(ESMF_KIND_R8), intent(inout) :: list(:)
- character(len=*) intent(inout) :: list(:)

Use Quick Sort, reverting to Insertion sort on lists of size \( \leq 20 \).

This is an ESMFized version of SLASRT from LAPACK version 3.1. Univ. of Tennessee, Univ. of California Berkeley and NAG Ltd. November 2006

The arguments are:

- **list** Array of data to be sorted. The original data is overwritten by the sorted data.
- **direction** Direction of sorting. Legal values are ESMF_SORT_ASCENDING and ESMF_SORT_DESCENDING.
- **[rc]** Return code; equals ESMF_SUCCESS if the sorting is successful.

Appendices

50 Appendix A: Master List of Constants

50.1 ESMF_ALARMLIST

This flag is documented in section 44.2.1.

50.2 ESMF_DIM_ARB

DESCRIPTION:
An integer named constant which is used to indicate that a particular dimension is arbitrarily distributed.

50.3 ESMF_ATTGETCOUNT

This flag is documented in section 38.6.1.

50.4 ESMF_ATTRECONCILE

DESCRIPTION:
Indicate whether or not to handle metadata (Attributes) in ESMF_StateReconcile().
The type of this flag is:
type(ESMF_AttReconcileFlag)
The valid values are:

ESMF_ATTRECONCILE_ON  Attribute reconciliation will be turned on.
ESMF_ATTRECONCILE_OFF  Attribute reconciliation will be turned off.

50.5 ESMF_ATTTREE

This flag is documented in section 38.6.2.

50.6 ESMF_ATTWRITE

This flag is documented in section 38.6.3.
50.7 ESMF_CALKIND

This flag is documented in section 40.2.1.

50.8 ESMF_COMPTYPE

DESCRIPTION:
Indicate the type of a Component.

The type of this flag is:

\texttt{type(ESMF\_CompType\_Flag)}

The valid values are:

- \texttt{ESMF\_COMPTYPE\_GRID} A \texttt{ESMF\_GridComp} object.
- \texttt{ESMF\_COMPTYPE\_CPL} A \texttt{ESMF\_CplComp} objects.
- \texttt{ESMF\_COMPTYPE\_SCI} A \texttt{ESMF\_SciComp} objects.

50.9 ESMF_CONTEXT

DESCRIPTION:
Indicates the type of VM context in which a Component will be executing its standard methods.

The type of this flag is:

\texttt{type(ESMF\_Context\_Flag)}

The valid values are:

- \texttt{ESMF\_CONTEXT\_OWN\_VM} The component is running in its own, separate VM context. Resources are inherited from the parent but can be arranged to fit the component’s requirements.
- \texttt{ESMF\_CONTEXT\_PARENT\_VM} The component uses the parent’s VM for resource management. Compared to components that use their own VM context components that run in the parent’s VM context are more lightweight with respect to the overhead of calling into their initialize, run and finalize methods. Furthermore, VM-specific properties remain unchanged when going from the parent component to the child component. These properties include the MPI communicator, the number of PETs, the PET labeling, communication attributes, threading-level.

50.10 ESMF_COORDSYS

DESCRIPTION:
A set of values which indicates in which system the coordinates in a class (e.g. Grid) are. This type is useful both to indicate to other users the type of the coordinates, but also to control how the coordinates are interpreted in ESMF methods which depend on the coordinates (e.g. regridding methods like \texttt{ESMF\_FieldRegrid\_Store()}).

The type of this flag is:

\texttt{type(ESMF\_CoordSys\_Flag)}
The valid values are:

ESMF_COORDSYS_CART Cartesian coordinate system. In this system, the cartesian coordinates are mapped to the Grid coordinate dimensions in the following order: x, y, z. (E.g. using coordDim=2 in ESMF_GridGetCoord() references the y dimension)

ESMF_COORDSYS_SPH_DEG Spherical coordinates in degrees. In this system, the spherical coordinates are mapped to the Grid coordinate dimensions in the following order: longitude, latitude, radius. (E.g. using coordDim=2 in ESMF_GridGetCoord() references the latitude dimension) Note, however, that ESMF_FieldRegridStore() currently just supports longitude and latitude (i.e. with this system, only Grids of dimension 2 are supported in the regridding).

ESMF_COORDSYS_SPH_RAD Spherical coordinates in radians. In this system, the spherical coordinates are mapped to the Grid coordinate dimensions in the following order: longitude, latitude, radius. (E.g. using coordDim=2 in ESMF_GridGetCoord() references the latitude dimension) Note, however, that ESMF_FieldRegridStore() currently just supports longitude and latitude (i.e. with this system, only Grids of dimension 2 are supported in the regridding).

This flag is documented in section 50.10

50.11 ESMF_COPY

DESCRIPTION:
Indicates which type of copy behavior is used when copying ESMF objects.

The type of this flag is:
type(ESMF_Copyright_Flag)

The valid values are:

ESMF_COPY_ALIAS The destination of the copy becomes an alias of the source object.
ESMF_COPY_REFERENCE All local data of the object is copied by value, and pointer valued data is referenced.
ESMF_COPY_VALUE All data and pointers are copied to the destination object, nothing is referenced.

50.12 ESMF_DATACOPY

DESCRIPTION:
Indicates whether to reference a data item or make a copy of it.

The type of this flag is:
type(ESMF_DataCopy_Flag)

The valid values are:

ESMF_DATACOPY_VALUE Copy the data item to another buffer.
ESMF_DATACOPY_REFERENCE Reference the data item.
50.13 ESMF_DECOMP

DESCRIPTION:
Indicates how DistGrid elements are decomposed over DEs.

The type of this flag is:
\texttt{type(ESMF\_Decomp\_Flag)}

The valid values are:

\texttt{ESMF\_DECOMP\_BALANCED} Decompose elements as balanced as possible across DEs. The maximum difference in number of elements per DE is 1, with the extra elements on the lower DEs.

\texttt{ESMF\_DECOMP\_CYCLIC} Decompose elements cyclically across DEs.

\texttt{ESMF\_DECOMP\_RESTFIRST} Divide elements over DEs. Assign the rest of this division to the first DE.

\texttt{ESMF\_DECOMP\_RESTLAST} Divide elements over DEs. Assign the rest of this division to the last DE.

50.14 ESMF_DIRECTION

This flag is documented in section 43.2.1

50.15 ESMF_DISTGRIDMATCH

This flag is documented in section 34.2.1

50.16 ESMF_END

This flag is documented in section 15.2.1

50.17 ESMF_FIELDSTATUS

This flag is documented in section 25.2.1

50.18 ESMF_FILEFORMAT

This flag is documented in section 30.2.7

50.19 ESMF_FILESTATUS

DESCRIPTION:
This flag is used in ESMF I/O functions. It’s use is similar to the \texttt{status} keyword in the Fortran \texttt{open} statement.

The type of this flag is:
\texttt{type(ESMF\_FileStatus\_Flag)}
The valid values are:

**ESMF_FILESTATUS_NEW**  The file must not exist, it will be created.

**ESMF_FILESTATUS_OLD**  The file must exist.

**ESMF_FILESTATUS_REPLACE**  If the file exists, all of its contents will be deleted before writing. If the file does not exist, it will be created.

**ESMF_FILESTATUS_UNKNOWN**  The value is treated as if it were **ESMF_FILESTATUS_OLD** if the corresponding file already exists. Otherwise, the value is treated as if it were **ESMF_FILESTATUS_NEW**.

### 50.20 ESMF_GEOMTYPE

**DESCRIPTION:**
Different types of geometries upon which an ESMF Field or ESMF Fieldbundle may be built.

The type of this flag is:

```c
int ESMF_GeomType_Flag
```

The valid values are:

**ESMF_GEOMTYPE_GRID**  An ESMF_Grid, a structured grid composed of one or more logically rectangular tiles

**ESMF_GEOMTYPE_MESH**  An ESMF_Mesh, an unstructured grid

**ESMF_GEOMTYPE_XGRID**  An ESMF_XGrid, an exchange grid

**ESMF_TYPEKIND_LOCSTREAM**  An ESMF_LocStream, a disconnected series of points with associated key values

### 50.21 ESMF_GRIDCONN

This flag is documented in section 30.2.1.

### 50.22 ESMF_GRIDITEM

This flag is documented in section 30.2.2.

### 50.23 ESMF_GRIDMATCH

This flag is documented in section 30.2.3.

### 50.24 ESMF_GRIDSTATUS

This flag is documented in section 30.2.4.
50.25 ESMF_INDEX

DESCRIPTION:
Indicates whether index is local (per DE) or global (per object).

The type of this flag is:
\texttt{type(ESMF\_Index\_Flag)}

The valid values are:

\textbf{ESMF_INDEX_DELOCAL} Indicates that DE-local index space starts at lower bound 1 for each DE.

\textbf{ESMF_INDEX_GLOBAL} Indicates that global indices are used. This means that DE-local index space starts at the global lower bound for each DE.

\textbf{ESMF_INDEX_USER} Indicates that the DE-local index bounds are explicitly set by the user.

50.26 ESMF_IOFMT

DESCRIPTION:
Indicates IO format options that are currently supported.

The type of this flag is:
\texttt{type(ESMF\_IOFmt\_Flag)}

The valid values are:

\textbf{ESMF_IOFMT_BIN} Binary format.

\textbf{ESMF_IOFMT_NETCDF} NETCDF and PNETCDF format.

50.27 ESMF_IO_NETCDF_PRESENT

DESCRIPTION:
Indicates whether netcdf feature support has been enabled within the current ESMF build.

The type of this flag is:
\texttt{logical}

The valid values are:

\texttt{.true.} Netcdf features are enabled.

\texttt{.false.} Netcdf features are not enabled.

50.28 ESMF_IOPIO_PRESENT

DESCRIPTION:
Indicates whether PIO (parallel IO) feature support has been enabled within the current ESMF build.
The type of this flag is:

logical

The valid values are:

.true. PIO features are enabled.
false. PIO features are not enabled.

**50.29 ESMF_IO_PNETCDF_PRESENT**

**DESCRIPTION:**
Indicates whether parallel netcdf feature support has been enabled within the current ESMF build.

The type of this flag is:

logical

The valid values are:

true. Parallel netcdf features are enabled.
false. Parallel netcdf features are not enabled.

**50.30 ESMF_ITEMORDER**

**DESCRIPTION:**
Specifies the order of items in a list.

The type of this flag is:

type(ESMF_ItemOrder_Flag)

The valid values are:

ESMF_ITEMORDER_ABC  The items are in alphabetical order, according to their names.
ESMF_ITEMORDER_ADDORDER  The items are in the order in which they were added to the container.

**50.31 ESMF_KIND**

**DESCRIPTION:**
Named constants to be used as *kind-parameter* in Fortran variable declarations. For example:

```fortran
integer(ESMF_KIND_I4) :: integerVariable
integer(kind=ESMF_KIND_I4) :: integerVariable
real(ESMF_KIND_R4) :: realVariable
real(kind=ESMF_KIND_R4) :: realVariable
```
The Fortran standard does not mandate what numeric values correspond to actual number of bytes allocated for the various kinds. The following constants are defined by ESMF to be correct across the supported Fortran compilers. Note that not all compilers support every kind listed below; in particular 1 and 2 byte integers can be problematic.

The type of these named constants is:

```
integer
```

The named constants are:

- `ESMF_KIND_I1` Kind-parameter for 1 byte integer.
- `ESMF_KIND_I2` Kind-parameter for 2 byte integer.
- `ESMF_KIND_I4` Kind-parameter for 4 byte integer.
- `ESMF_KIND_I8` Kind-parameter for 8 byte integer.
- `ESMF_KIND_R4` Kind-parameter for 4 byte real.
- `ESMF_KIND_R8` Kind-parameter for 8 byte real.

### 50.32 ESMF_LINETYPE

**DESCRIPTION:**

This argument allows the user to select the path of the line which connects two points on the surface of a sphere. This in turn controls the path along which distances are calculated and the shape of the edges that make up a cell.

The type of this flag is:

```
type(ESMF_LineType_Flag)
```

The valid values are:

- `ESMF_LINETYPE_CART` Cartesian line. When this option is specified distances are calculated in a straight line through the 3D Cartesian space in which the sphere is embedded. Cells are approximated by 3D planes bounded by 3D Cartesian lines between their corner vertices. When calculating regrid weights, this line type is currently the default for the following regrid methods: ESMF_REGRIDMETHOD_BILINEAR, ESMF_REGRIDMETHOD_PATCH, ESMF_REGRIDMETHOD_NEAREST_STOD, and ESMF_REGRIDMETHOD_NEAREST_DTOS.

- `ESMF_LINETYPE_GREAT_CIRCLE` Great circle line. When this option is specified distances are calculated along a great circle path (the shortest distance between two points on a sphere surface). Cells are bounded by great circle paths between their corner vertices. When calculating regrid weights, this line type is currently the default for the following regrid method: ESMF_REGRIDMETHOD_CONSERVE.

### 50.33 ESMF_LOGERR

This flag is documented in section 46.2.1.

### 50.34 ESMF_LOGKIND

This flag is documented in section 46.2.2.
50.35 ESMF_LOGMSG
This flag is documented in section 46.2.3.

50.36 ESMF_MESHELEMENTYPE
This flag is documented in section 32.2.1.

50.37 ESMF_MESHLOC
DESCRIPTION:
Used to indicate a specific part of a Mesh. This is commonly used to specify the part of the Mesh to create a Field on.
The type of this flag is:
type(ESMF_MeshLoc)
The valid values are:

ESMF_MESHLOC_NODE The nodes (also known as corners or vertices) of a Mesh.
ESMF_MESHLOC_ELEMENT The elements (also known as cells) of a Mesh.

50.38 ESMF_MESHOP
DESCRIPTION:
Specifies the spatial operation with two source Meshes, treating the Meshes as point sets.
The type of this flag is:
type(ESMF_MeshOp_Flag)
The valid values are:

ESMF_MESHOP_DIFFERENCE Calculate the difference of the two point sets from the source Meshes.

50.39 ESMF_METHOD
DESCRIPTION:
Specify standard ESMF Component method.
The type of this flag is:
type(ESMF_Method_Flag)
The valid values are:

ESMF_METHOD_FINALIZE Finalize method.
ESMF_METHOD_INITIALIZE Initialize method.
ESMF_METHOD_READRESTART ReadRestart method.

ESMF_METHOD_RUN Run method.

ESMF_METHOD_WRITERESTART WriteRestart method.

50.40 ESMF_PIN

This flag is documented in section 47.2.1.

50.41 ESMF_POLEKIND

This flag is documented in section 30.2.5.

50.41.1 ESMF_POLEMETHOD

DESCRIPTION:

When interpolating between two Grids which have been mapped to a sphere these can be used to specify the type of artificial pole to create on the source Grid during interpolation. Creating the pole allows destination points above the top row or below the bottom row of the source Grid to still be mapped.

The type of this flag is:

type(ESMF_PoleMethod_Flag)

The valid values are:

ESMF_POLEMETHOD_NONE No pole. Destination points which lie above the top or below the bottom row of the source Grid won’t be mapped.

ESMF_POLEMETHOD_ALLAVG Construct an artificial pole placed in the center of the top (or bottom) row of nodes, but projected onto the sphere formed by the rest of the grid. The value at this pole is the average of all the source values surrounding the pole.

ESMF_POLEMETHOD_NPNTAVG Construct an artificial pole placed in the center of the top (or bottom) row of nodes, but projected onto the sphere formed by the rest of the grid. The value at this pole is the average of the N source nodes next to the pole and surrounding the destination point (i.e. the value may differ for each destination point). Here N is set by using the regridPoleNPnts parameter and ranges from 1 to the number of nodes around the pole. This option is useful for interpolating values which may be zeroed out by averaging around the entire pole (e.g. vector components).

ESMF_POLEMETHOD_TEETH No new pole point is constructed, instead the holes at the poles are filled by constructing triangles across the top and bottom row of the source Grid. This can be useful because no averaging occurs, however, because the top and bottom of the sphere are now flat, for a big enough mismatch between the size of the destination and source pole holes, some destination points may still not be able to be mapped to the source Grid.
50.42 ESMF_REDUCE

DESCRIPTION:
Indicates reduce operation

The type of this flag is:
`type(ESMF_Reduce_Flag)`

The valid values are:

- **ESMF_REDUCE_SUM**: Use arithmetic sum to add all data elements.
- **ESMF_REDUCE_MIN**: Determine the minimum of all data elements.
- **ESMF_REDUCE_MAX**: Determine the maximum of all data elements.

50.43 ESMF_REGION

DESCRIPTION:
Specifies various regions in the data layout of an Array or Field object.

The type of this flag is:
`type(ESMF_Region_Flag)`

The valid values are:

- **ESMF_REGION_TOTAL**: Total allocated memory.
- **ESMF_REGION_SELECT**: Region of operation-specific elements.
- **ESMF_REGION_EMPTY**: The empty region contains no elements.

50.43.1 ESMF_REGRIDMETHOD

DESCRIPTION:
Specify which interpolation method to use during regridding. For a more detailed discussion of these methods, as well as ESMF regridding in general, see Section 23.2.

The type of this flag is:
`type(ESMF_RegridMethod_Flag)`

The valid values are:

- **ESMF_REGRIDMETHOD_BILINEAR**: Bilinear interpolation. Destination value is a linear combination of the source values in the cell which contains the destination point. The weights for the linear combination are based on the distance of destination point from each source value.
- **ESMF_REGRIDMETHOD_PATCH**: Higher-order patch recovery interpolation. Destination value is a weighted average of 2D polynomial patches constructed from cells surrounding the source cell which contains the destination point. This method typically results in better approximations to values and derivatives than bilinear. However, because of its larger stencil, it also results in a much larger interpolation matrix (and thus routeHandle) than the bilinear.
**ESMF_REGRIDMETHOD_NEAREST_STOD** In this version of nearest neighbor interpolation each destination point is mapped to the closest source point. A given source point may go to multiple destination points, but no destination point will receive input from more than one source point.

**ESMF_REGRIDMETHOD_NEAREST_DTOS** In this version of nearest neighbor interpolation each source point is mapped to the closest destination point. A given destination point may receive input from multiple source points, but no source point will go to more than one destination point.

**ESMF_REGRIDMETHOD_CONSERVE** First order conservative interpolation. Value of a destination cell is the weighted sum of the values of the source cells that it overlaps. The weights are determined by the amount the source cell overlaps the destination cell. Will typically give less accurate approximations to values than the other interpolation methods, however, will do a much better job preserving the integral of the value between the source and destination. Needs corner coordinate values to be provided in the Grid. Currently only works for Fields created on the Grid center stagger (or the Mesh element location).

### 50.44 ESMF_ROUTESYNC

**DESCRIPTION:**

Switch between blocking and non-blocking execution of RouteHandle based communication calls. Every RouteHandle based communication method contains an optional argument `routesyncflag` that is of type `ESMF_RouteSync_Flag`.

The type of this flag is:

```
type(ESMF_RouteSync_Flag)
```

The valid values are:

**ESMF_ROUTESYNC_BLOCKING** Execute a precomputed communication pattern in blocking mode. This mode guarantees that when the method returns all PET-local data transfers, both in-bound and out-bound, have finished.

**ESMF_ROUTESYNC_NBSTART** Start executing a precomputed communication pattern in non-blocking mode. When a method returns from being called in this mode, it guarantees that all PET-local out-bound data has been transferred. It is now safe for the user to overwrite out-bound data elements. No guarantees are made for in-bound data elements at this stage. It is unsafe to access these elements until a call in `ESMF_ROUTESYNC_NBTETFINISH` mode has been issued and has returned with `finishedflag` equal to `.true.`. or a call in `ESMF_ROUTESYNC_NBWAITFINISH` mode has been issued and has returned.

**ESMF_ROUTESYNC_NBTETFINISH** Test whether the transfer of data of a precomputed communication pattern, started with `ESMF_ROUTESYNC_NBSTART`, has completed. Finish up as much as possible and set the `finishedflag` to `.true.` if all data operations have completed, or `.false.` if there are still outstanding transfers. Only after a `finishedflag` equal to `.true.` has been returned is it safe to access any of the in-bound data elements.

**ESMF_ROUTESYNC_NBWAITFINISH** Wait (i.e. block) until the transfer of data of a precomputed communication pattern, started with `ESMF_ROUTESYNC_NBSTART`, has completed. Finish up all data operations and set the returned `finishedflag` to `.true..` It is safe to access any of the in-bound data elements once the call has returned.

**ESMF_ROUTESYNC_CANCEL** Cancel outstanding transfers for a precomputed communication pattern.
50.45  **ESMF_SERVICEREPLY**

This flag is documented in section 47.2.

50.46  **ESMF_STAGGERLOC**

This flag is documented in section 30.2.

50.47  **ESMF_STARTREGION**

**DESCRIPTION:**
Specifies the start of the effective halo region of an Array or Field object.

The type of this flag is:

type(ESMF_StartRegion_Flag)

The valid values are:

ESMF_STARTREGION_EXCLUSIVE  Region of elements that are exclusively owned by the local DE.
ESMF_STARTREGION_COMPUTATIONAL  User defined region, greater or equal to the exclusive region.

50.48  **ESMF_STATEINTENT**

This flag is documented in section 20.2.

50.49  **ESMF_STATEITEM**

This flag is documented in section 20.2.

50.50  **ESMF_SYNC**

**DESCRIPTION:**
Indicates method blocking behavior and PET synchronization for VM communication methods, as well as for standard Component methods, such as Initialize(), Run() and Finalize().

For VM communication calls the ESMF_SYNC_BLOCKING and ESMF_SYNC_NONBLOCKING modes provide behavior that is practically identical to the blocking and non-blocking communication calls familiar from MPI.

The details of how the blocking mode setting affects Component methods are more complex. This is a consequence of the fact that ESMF Components can be executed in threaded or non-threaded mode. However, in the default, non-threaded case, where an ESMF application runs as a pure MPI or mpiuni program, most of the complexity is removed.

See the VM item in 6.5 for an explanation of the PET and VAS concepts used in the following descriptions.

The type of this flag is:
type(ESMF_Sync_Flag)

The valid values are:

ESMF_SYNC_BLOCKING  Communication calls: The called method will block until all (PET-)local operations are complete. After the return of a blocking communication method it is safe to modify or use all participating local data.

  Component calls: The called method will block until all PETs of the VM have completed the operation.

For a non-threaded, pure MPI component the behavior is identical to calling a barrier before returning from the method. Generally this kind of rigid synchronization is not the desirable mode of operation for an MPI application, but may be useful for application debugging. In the opposite case, where all PETs of the component are running as threads in shared memory, i.e. in a single VAS, strict synchronization of all PETs is required to prevent race conditions.

ESMF_SYNC_VASBLOCKING  Communication calls: Not available for communication calls.

  Component calls: The called method will block each PET until all operations in the PET-local VAS have completed.

This mode is a combination of ESMF_SYNC_BLOCKING and ESMF_SYNC_NONBLOCKING modes. It provides a default setting that leads to the typically desirable behavior for pure MPI components as well as those that share address spaces between PETs.

For a non-threaded, pure MPI component each PET returns independent of the other PETs. This is generally the expected behavior in the pure MPI case where calling into a component method is practically identical to a subroutine call without extra synchronization between the processes.

In the case where some PETs of the component are running as threads in shared memory ESMF_SYNC_VASBLOCKING becomes identical to ESMF_SYNC_BLOCKING within thread groups, to prevent race conditions, while there is no synchronization between the thread groups.

ESMF_SYNC_NONBLOCKING  Communication calls: The called method will not block but returns immediately after initiating the requested operation. It is unsafe to modify or use participating local data before all local operations have completed. Use the ESMF_VMCommWait() or ESMF_VMCommQueueWait() method to block the local PET until local data access is safe again.

  Component calls: The behavior of this mode is fundamentally different for threaded and non-threaded components, independent on whether the components use shared memory or not. The ESMF_SYNC_NONBLOCKING mode is the most complex mode for calling component methods and should only be used if the extra control, described below, is absolutely necessary.

For non-threaded components (the ESMF default) calling a component method with ESMF_SYNC_NONBLOCKING is identical to calling it with ESMF_SYNC_VASBLOCKING. However, different than for ESMF_SYNC_VASBLOCKING, a call to ESMF_GridCompWait() or ESMF_CplCompWait() is required in order to deallocate memory internally allocated for the ESMF_SYNC_NONBLOCKING mode.

For threaded components the calling PETs of the parent component will not be blocked and return immediately after initiating the requested child component method. In this scenario parent and child components will run concurrently in identical VASs. This is the most complex mode of operation. It is unsafe to modify or use VAS local data that may be accessed by concurrently running components until the child component method has completed. Use the appropriate ESMF_GridCompWait() or ESMF_CplCompWait() method to block the local parent PET until the child component method has completed in the local VAS.
50.51 ESMF_TERMORDER

DESCRIPTION:
Specifies the order of source terms in a destination sum, e.g. during sparse matrix multiplication.

The type of this flag is:

\[ \text{type}(\text{ESMF\_TermOrder\_Flag}) \]

The valid values are:

- **ESMF_TERMORDER_SRCSEQ** The source terms are in strict ascending order according to their source sequence index.
- **ESMF_TERMORDER_SRCPET** The source terms are first ordered according to their distribution across the source side PETs: for each destination PET the source PET order starts with the localPet and decrements from there, modulo petCount, until all petCount PETs are accounted for. The term order within each source PET is given by the source term sequence index.
- **ESMF_TERMORDER_FREE** There is no prescribed term order. The source terms may be summed in any order that optimizes performance.

50.52 ESMF_TYPEKIND

DESCRIPTION:
Named constants used to indicate type and kind combinations supported by the overloaded ESMF interfaces. The corresponding Fortran kind-parameter constants are described in section 50.31.

The type of these named constants is:

\[ \text{type}(\text{ESMF\_TypeKind\_Flag}) \]

The named constants are:

- **ESMF_TYPEKIND_I1** Indicates 1 byte integer.
- **ESMF_TYPEKIND_I2** Indicates 2 byte integer.
- **ESMF_TYPEKIND_I4** Indicates 4 byte integer.
- **ESMF_TYPEKIND_I8** Indicates 8 byte integer.
- **ESMF_TYPEKIND_R4** Indicates 4 byte real.
- **ESMF_TYPEKIND_R8** Indicates 8 byte real.

50.53 ESMF_UNMAPPEDACTION

DESCRIPTION:
Indicates what action to take with respect to unmapped destination points and the entries of the sparse matrix that correspond to these points.

The type of this flag is:

\[ \text{type}(\text{ESMF\_UnmappedAction\_Flag}) \]
The valid values are:

**ESMF_UNMAPPED_ACTION_ERROR** An error is issued when there exist destination points in a regridding operation that are not mapped by corresponding source points.

**ESMF_UNMAPPED_ACTION_IGNORE** Destination points which do not have corresponding source points are ignored and zeros are used for the entries of the sparse matrix that is generated.

### 50.54 ESMF_VERSION

**DESCRIPTION:**
The following named constants define the precise version of ESMF in use.

**ESMF_VERSION_BETASNAPSHOT** Constant of type logical indicating beta snapshot phase (.true. for any version during the pre-release development phase, .false. for any released version of the software).

**ESMF_VERSION_MAJOR** Constant of type integer indicating the major version number (e.g. 5 for v5.2.0r).

**ESMF_VERSION_MINOR** Constant of type integer indicating the minor version number (e.g. 2 for v5.2.0r).

**ESMF_VERSION_PATCHLEVEL** Constant of type integer indicating the patch level of a specific revision (e.g. 0 for v5.2.0r, or 1 for v5.2.0rp1).

**ESMF_VERSION_PUBLIC** Constant of type logical indicating public vs. internal release status (e.g. .true. for v5.2.0r, or .false. for v5.2.0).

**ESMF_VERSION_REVISION** Constant of type integer indicating the revision number (e.g. 0 for v5.2.0r).

**ESMF_VERSION_STRING** Constant of type character holding the exact release version string (e.g. "5.2.0r").

### 50.55 ESMF_XGRIDSIDE

This flag is documented in section 33.2.1.

### 51 Appendix B: A Brief Introduction to UML

The schematic below shows the Unified Modeling Language (UML) notation for the class diagrams presented in this Reference Manual. For more on UML, see references such as *The Unified Modeling Language Reference Manual*, Rumbaugh et al. [23].
ClassA

Public class. This is a class whose methods can be called by the user. In Fortran a public class is usually associated with a derived type and a corresponding module that contains class methods and flags.

ClassB

Private class. This type of class does not have methods that should be called by the user. Like a public class it is usually associated with a derived type and a corresponding module.

A line indicates some sort of association among classes.

A hollow diamond at one end of a line drawn between classes represents an association called aggregation. Aggregation is a part-whole relationship that can be read as “the class at the end of the line without the diamond is part of the class at the end of the line with the diamond.” The class that is the “part” can be created and destroyed separately, and it is usually implemented as a reference contained with the structure of the class that is the “whole.”

A filled diamond at one end of a line drawn between classes represents an association called composition. Composition is a part-whole relationship that is similar to aggregation, but stronger. It implies that that class that is the “part” is created and destroyed by the class that is the “whole.” It is often implemented as a structure within part of the contiguous memory of a larger structure.

Multiplicity indicators at association line ends show how many classes on the one end are associated with how many classes on the other end.

The triangle indicates an inheritance relationship. Inheritance means that a child class shares a set of characteristics (such as the same attributes or methods) with a parent class. The child can specialize and extend the behavior of the parent. This diagram shows a GridComp class that inherits from a more general Comp class.

This simple diagram shows that a public class called Field is associated with another public class, called Grid. The aggregation relationship indicated by the unfilled diamond means that a Field contains a Grid, but that a Grid can be created and destroyed outside of a Field. The diagram multiplicities show that a Field can be associated with no Grid or with one Grid, but that a single Grid can be associated with any number of Fields.

52 Appendix C: ESMF Error Return Codes

The tables below show the possible error return codes for Fortran and C methods.
